Having thus briefly described the character of the processes, attention may be turned to the machinery producing the electric current, the sole active agent employed in their operation. This is at present generated by two shunt-wound dynamos by Messrs. C. A. Parsons and Co., of Newcastle-upon-Tyne. These are driven direct upon the shafts of two of the same firm's steam turbines, the combination being technically known as Parson's parallel-flow steam turbo-dynamos. Separate condensers are worked by two of Messrs. Robey and Co.'s compound inverted engines, an excellent vacuum being steadily maintained. The revolutions of the turbines and dynamos number 3200 per minute. With a working pressure of 160 lb., each turbine developes 700-horse power. Steam at that pressure is supplied by a battery of five steel Lancashire boilers, each 30ft. long by 8ft. diameter, by Messrs. Beeley, of Hyde, one of the five being held as a reserve. The feed-water for these is from the town supply, and is stated to be very hard; that for condensing is freely obtained through a 16in. cast iron pipe from the adjacent canal, to which it is returned after use. The stack is situated about 200ft. from the boilers; it has a height of 180ft., with an average internal diameter of 15ft. A Green's economiser is fixed at the rear of the boiler battery.

Each of the two dynamos yields a working current of 3500 ampères, a total of 7000 ampères, which is subdivided into ten currents of 700 ampères each. A switchboard, by Messrs. C. A. Parsons and Co., provides for the distribution of these currents; upon it are two Weston ammeters for 4000 ampères each, and a Weston voltmeter, the ten currents being each provided with separate ammeters. From each side of the switchboard five cables lead to the decomposing tanks before described.

The advantages claimed for this electrolytic process are manifold. That of the first importance is cheapness.

THE ACCIDENT ON THE SNOWDON RACK RAILWAY

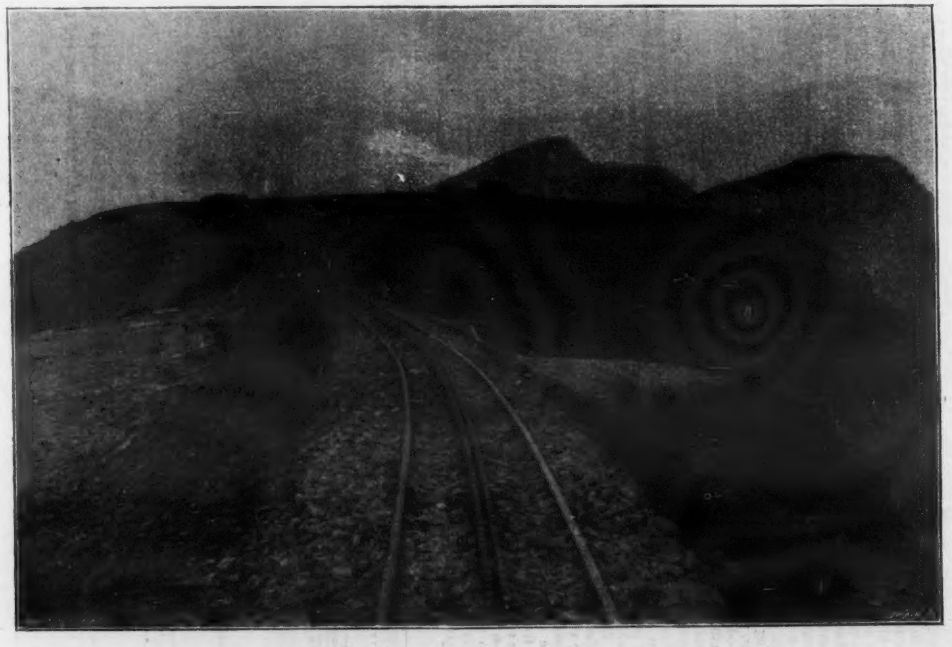
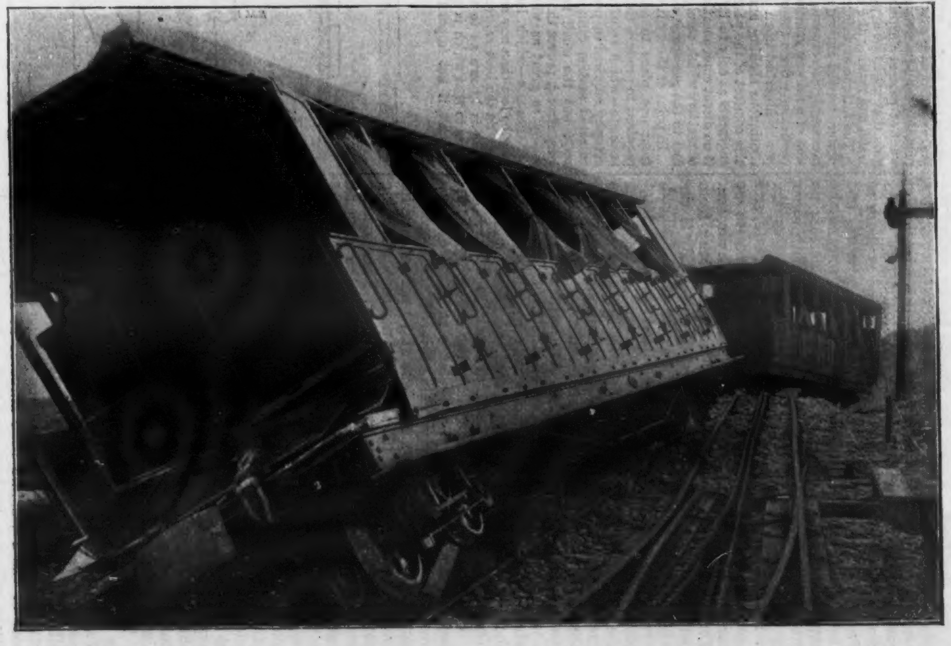
No. 1—VIEW FROM FINAL POSITION OF DERAILED CARRIAGES



No. 2—VIEW FROM POINT WHERE ENGINE LEFT RAILS

No. 3—VIEW FROM FRONT OF DERAILED CARRIAGES SHOWING SECOND TRAIN



No. 4—THE DERAILED CARRIAGES

The chairman of the company recently stated that by it both the caustic soda and the bleaching powder could be produced at about half the cost of that by any other system practised. Under the patents before named the use of diaphragms, which offer great resistance to the electric current, is dispensed with, while the adoption of gas-retort carbon for the anodes has completely solved the economic difficulty of the costly wastage of these at first experienced. The use of sulphur, pyrites, and manganese, being also dispensed with, not only is the expense of these costly agents saved, but there is no production of the noxious alkali "waste." With other processes, to produce one ton of caustic soda involves the production of from three to four tons of that waste, and streams adjacent to the works where such processes are carried on become poisoned with sulphuretted hydrogen. The working of the new system we can testify from personal observation to be wholly inodorous. By it the whole of the chlorine in the decomposed salt is utilised, whereas it is said that in the Le Blanc process at least 50 per cent. of this is lost. It is further claimed that the caustic soda produced is purer, as being wholly free from the sulphides or other sulphur compounds used in the older processes. As to this claim for quality, we may quote a report by Messrs. A. Norman Tate and Co., analytical and consulting chemists, of Liverpool, which certifies that the caustic soda manufactured by the company contains 70 per cent. of alkali, and the bleaching powder 37·4 per cent. of available chlorine.

It cannot create surprise that, the foregoing advantages being established, a very large measure of commercial success has already been achieved. The present capacity of output is about 60 tons of 70 per cent. white caustic soda, and about 100 tons of 35 per cent. bleaching powder, from 60 tons of common salt weekly. This capacity has been found quite insufficient to meet the demand upon the works. The chairman of the company informed a meeting of the shareholders held November 5th of last year, that all that could be produced with the present plant during 1896 had been sold in advance at "top" prices. It became necessary, therefore, to erect plant adequate to a great increase in production. Orders were at once placed for the required new machinery, and it is expected that this will be working within the course of the next three months, the required extension of the buildings to receive it being already well advanced at the time of our visit to the works.

The machines at present under construction will vary in types from that we have above described. Messrs. Yates and Thom, of Blackburn, have in hand four compound inverted cylinder engines, which will indicate in all 3600-horse power. They will be worked at eighty revolutions, and will drive by rope gearing eight dynamos, each of these yielding 1500 ampères at 180 volts. The works will then be furnished with a total of 5000 indicated horse-power, or approaching four times their present capacity of 1400 indicated horse-power.

We alluded in the course of our description of the processes to the success attained by the use of the new forms of anodes constructed of gas-retort carbon. It will be of interest to refer more particularly to these. The deposit which lines the retorts in gas manufacture has until quite recently been regarded almost as a waste product, it having little or no marketable value. On our late visit to the Electro-Chemical Company's works we were shown many tons of this carbon. We were struck by the difference in the grain and weight between such of this as had been obtained from London gasworks and that purchased from those in districts beyond that area. Anodes constructed with the London-produced carbon are found to have a materially longer life than those made of the country product. For the formation of these anodes the carbon is broken into rough pieces about the size of the hand, a lug being sawn upon each piece. Seven or eight of these are arranged in a frame which holds them inverted in the brine.

It is not within our province to express opinion as to the commercial value of particular systems, and we content ourselves with putting before our readers the statements made by the company. In conclusion, we would express our thanks to the courteous manager of the works, Mr. J. Leith, to whose perseverance and chemical and other experiences much of the practical success attained has undoubtedly been due, for the assistance and ready explanations afforded to us on the occasion of our visit.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

PERMANENT WAY.

Sir,—There is, as a rule, no more certain indication of power being wasted than when noise is made in connection with machinery. A train moving at high speed makes a great deal of noise. Probably many hundreds of men striking with sledge hammers on sleepers and rails would not make as much noise, or cause as much vibration as a passing train. Indeed the motion of a train at high speed produces an effect not unlike hammering, and, reasoning by analogy, the power of the engine must be largely consumed, not only in producing jolting, or visible vibration, but in setting up microscopic, or even molecular tremors in the ground and in the train. If a train could be made to move along the rails as sweetly and smoothly as the crosshead of the piston-rod glides along its guide bars it would be an ideal state of matters. This perfection of motion is, of course, impossible of accomplishment, but a consideration of what is theoretically perfect often points the way to practical improvement.

When one watches the wheels of a train passing slowly along the rails, the latter are seen to sink under the weight. When the motion of the train is very rapid the depression must be made as with a blow. It would therefore appear, that in order to avoid this shock, and consequent waste of energy, the weight should be brought to bear as gradually as possible. If this reasoning is correct, an engine having its leading wheels coupled—a type somewhat rare brings great weight to bear on the track instantaneously, and must therefore be more wasteful of energy than the type having a bogie in front, where more lightly loaded wheels depress the rails gradually. It has been noticed that the front of a train is, as it were, always running uphill. This is true, but it is not nearly the whole truth. The distance between successive wheels is usually so great that the rails spring up after each wheel has passed, so that the whole train may be said to be running up hill. Of course, when the speed is slow, this is a fallacious view, as the wheels may be said with equal truth to be running down hill. At highest velocities this downward slope behind the wheels gives probably no advantage, owing to the inertia of the track and its want of perfect elasticity. The accompanying diagram shows the gain that might be expected to arise from grouping the wheels in a train, and making the carriages of the long American type.

The fatigue experienced by a passenger is one result of engine power wasted through vibration or jolting. Vibration is not necessarily accompanied by great waste of power, but the vibration of a railway vehicle is accompanied with much waste of power, particularly when the load is not composed of rigid material. The power absorbed when hundreds of passengers are subjected to a continuous shaking and swaying is probably not inconsiderable. The comfort of the passengers is, perhaps, looked upon by railway engineers as only to be enhanced by expenditure for which there is no direct compensation. It will, no doubt, be found that a state of matters which results in smooth motion, and consequent comfort to the passenger, is a real practical economy.

In point of theory it does not require any power to move matter from one place to another on the same level beyond what is required to produce the rate of motion at which the transference is made—which is, of course trifling in comparison with the force actually required in practice. The resistance of the atmosphere to rapid motion cannot be materially diminished in any practical way, but the small retarding effect of head winds, even when very strong, proves that the resistance from this cause cannot be nearly so great as was at one time believed. Resistance from other causes—which, looked at from the theoretical point of view, may be less than any assignable amount—is in practice very great, even on the best railroads, when the speed is high. Apparently little is known as to the ratio which this great waste of power bears to that which is practically remediable; indeed, it would be difficult, if not impossible, to give even an approximation to the relative amount of power absorbed by the train and the track—that is, the amount of energy destroyed above, as compared with that destroyed below the surface of the rails. Certainly no small amount of force is necessary to produce the earthquake that always accompanies a train.

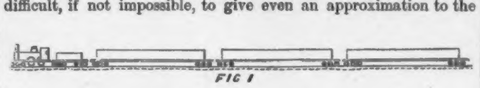


FIG 1

FIG 2

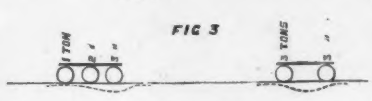

FIG 3

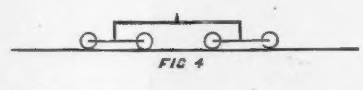

FIG 4

FIG 5

FIG 6

FIG 7

Fig. 1 is a train of long carriages supported on bogies, wheels all in groups, and as close as possible to each other; centre wheels without flanges. Fig. 2 is a train of ordinary carriages, wheels at nearly equal spaces apart. A comparison of the dotted lines showing rail deflection indicates the advantage of the former arrangement, which produces three deflections from the carriages as compared with twelve, and with slighter gradients. Fig. 3 shows the wheels of a bogie, weighted with successively higher amounts, compared with a case where the weight is equal on all wheels. Fig. 4 is a compound lever work to neutralise vibration. Practical value very doubtful. Fig. 5 indicates the path of a ball thrown along the ground, showing the effect of slight inequalities or obstacles in raising the ball when its motion is swift. Fig. 6 gives the wheel spaces agreeing with sleeper spaces, producing vertical vibration. Fig. 7 the wheel spaces regulated to prevent such vibration.
J. C.

Edinburgh, April 4th.

Sir,—It is with great surprise I read in The Engineer of 27th a letter headed Permanent Way, in which the writer states that in his opinion a road constructed absolutely rigid and uniform would be not only tolerable but perfect.

Past experience goes to show otherwise, for in the book, "Safe Railway Working," by Stretton, page 23, we see an attempt to obtain a firm permanent way was made upon the Manchester and Leeds Railway in 1839. One part of the line passed for some distance through a rock cutting, and instead of using sleepers the solid rock was dressed to a surface, and the chairs spiked directly to it. The company's officials concluded, and expected that this portion of the line would stand firm for ever. However, the road was so rigid that if a train passed over it at more than a walking pace, rails and springs were broken, and in less than three weeks from the opening of the railway orders were given for the rails to be taken up and placed upon sleepers in the ordinary way.

The lesson taught us here is that a certain amount of elasticity or give-and-take is required between the rails and the train. We all know, more or less, what a carriage without springs would be, and a rigid road would be like the carriage without springs. Again, the large amount of vibration caused to the locomotive alone would be very detrimental, to say the least. It is a well-known thing that iron, by constant vibration, becomes quite brittle. The parts of a locomotive now become very brittle quite quick enough. Therefore, no system of permanent way is required which will increase this difficulty. Whilst serving my time in the locomotive shops I have seen parts of locomotives taken down quite brittle and crystallised. Should in the future the permanent way be made rigid, as your correspondent advocates, there will be a very prosperous future for the manufacturers of springs.

April 7th. F. J. P.

CIRCULATION IN WATER-TUBE BOILERS.

Sir,—The following easy experiment may throw light on the difficulty which you discuss in your leading article of the 3rd, regarding the cause of circulation in boiler pipes, so far as it depends on the presence of bubbles of steam: Take two pieces of glass tube ½in. internal, connected by india-rubber tube, glass about 15in. long. Also a bottle with a good pouring lip, containing—only half-full—equal quantities, say, of sweet oil and water. Suck up some plain water from a jug to fill both tubes, and turn them up as a U. Suck up one till the water sinks in the other to the rubber tube, and hold it there by pressing the thumb tight on the top of the full limb, and then raise the empty limb till its top stands a couple of inches higher than that of the full limb. With the other hand shake up the bottle till oil and water are well mixed, and quickly fill the empty limb by its open mouth with the mixture to the level of the water in the thumb-stopped limb.

The apparatus is now ready for demonstration, the thumb being still tight pressed over the limb which has pure water in it; the liquids in the two limbs stand at the same level, but the limb containing water with loose drops of a lighter substance—oil—scattered about in it is a few inches longer than the other. Now remove the thumb, and let the liquid find its own level. What will happen? Circulation will instantly set in towards the limb which has the lighter drops of liquid scattered about in the water. The two columns are of the same height, and the same sectional area. One sinks down and the other rises up immediately to a certain point, and there they rest.

Is it not a good and sufficient explanation to say that the former is heavier than the latter?

Is it true to say that the reason why the oil mixture rises up is that the little drops of oil are all floating upwards, and entrain the water?
Senex.

April 6th.

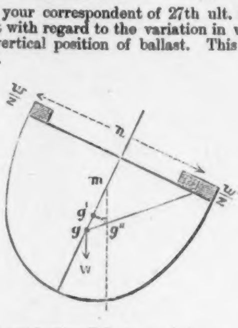
Sir,—I venture to point out a mistake in your last issue. On page 335 you have the following:—"The statement again, that in the Belleville boiler there is no circulation whatever in the commonly accepted sense of the word, evoked no contradiction from anyone present, and appears to be borne out by the behaviour of the large model shown at work, in which the bubbles of steam coursed regularly through the tubes, albeit no circulation of the water took place."

This is not in accordance with the following extract from my paper—see page 351 of same issue:—"When properly in action, the circulation is very vigorous and thorough, the alternate plugs of water and steam racing each other through the tubes of the element at a very high speed."
W. H. Watkinson.

Glasgow, April 8th.

NAVAL ARCHITECTURE—NO. IV., STABILITY.

Sir,—I think your correspondent of 27th ult. is hardly correct in his statement with regard to the variation in value of G M due to variation in vertical position of ballast. This seems to be not obvious *a priori*.



In the figure let G be the C G of vessel alone, and $\frac{w}{2}$ the weight of ballast placed on either side of middle line, and G′ the common C G of vessel and ballast; when $\frac{w}{2}$ is shifted across we have—

$$G' M = G' G'' \cot \theta = \frac{w x}{2 (W + w)} \cot \theta \text{ when } W = \text{weight or}$$

displacement of vessel.

Suppose x to remain constant for any vertical position of the ballast; now θ must be kept within the limits of inclination, for which the metacentric method holds true—*i.e.*, θ must be not > about 10 deg. Now for greater distances above G at which the ballast is placed, so θ will increase, since for same weight of ballast greater leverage of the latter results when vessel is inclined. Hence w must be reduced for higher positions of ballast if θ is to be kept within the limits, and hence $\frac{w x}{2 (W + w)} \cot \theta = G' M$ will be correspondingly reduced. Now G G′ will depend both on w and its vertical position, and it will be found that this vertical position will have greater effect on the value of G G′ than the diminution of w explained above, so that G G′ will increase; and since G′ M was diminished, there will be a tendency to compensation, so that G M (= G G′ + G′ M) will remain practically the same.
B. C. Laws.

Royal College of Science, S.W., April 2nd.

THE LIQUEFACTION OF GASES.

Sir,—The theory put forward by "Zero" as to the action of Dr. Hampson's machine for liquefying oxygen is very interesting but not quite convincing.

He says, "there is no loss of energy or heat at all from the apparatus as a whole." But energy or heat is being steadily expended on the apparatus by a steam engine; what becomes of it? If it cannot get out and is being stored up in the machine, why does not the latter burst, or get red hot, or do something violent? If cold is localised at one point, heat must be localised at another, and with the accumulation of oxygen from which heat has been abstracted there must be an accumulation of heat in some part of the apparatus. On "Zero's" theory, in the felted cylinder there ought to be a hot place which gets increasingly hot the longer the apparatus works. Does experiment prove this to be the case?

Experiment, too, would easily settle the correctness or otherwise of "Zero's" contention that what he calls Joule's effect has nothing to do with the working of the machine. Let compressed hydrogen, at the temperature of water from the main, be passed through Dr. Hampson's machine. If "Zero" is right, the hydrogen will behave as oxygen does under similar circumstances and produce cold. But if no cold is produced there will be a presumption that Joule's effect is operative in the matter, and that "Zero's" theory is wrong. The issue of the experiment would probably lead "Zero" to re-examine Joule's and Thomson's results, and he might find in them the key to the explanation of the thermo-dynamic puzzle that troubles him.

He is filled with pity for "dogmatic science," and for the thermo-dynamic blindness of learned professors. But he might remember that "dogmatic science," in the person of Professor Dewar, did originate an apparatus, in which, as in Hampson's, intense cold was produced by the expansion of gas at high pressure through a minute orifice before Hampson had actually constructed his machine, and before he received a patent. Even now, I believe, Dr. Hampson's patent has not yet been granted, much less published.

April 6th. Cryos.

[Our correspondent is in error. Dr. Hampson obtained his patent on the 23rd of May, 1895.—Ed. E.]

CANAL AND LIGHT RAILWAY LEGISLATION.

Sir,—A movement has been organised in Ireland to press on the Government the desirability of extending to canal construction, and to river navigation generally, the provisions of the forthcoming Light Railways Bill with regard to obtaining money on loans from the Treasury, and facilities for obtaining inexpensively the necessary Acts for the construction of the works.

Those interested in inland navigation in England would do well to avail themselves of the present opportunity by supporting the movement made on this side.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

**** In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

**** All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

**** We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

E. BEADLE.—*It is generally believed that the use of a tube for ignition, as in the case you mention, is free to all.*

A. E. E.—"*A Treatise on Marine Surveying,*" *by Rev. J. L. Robinson, M.A. London: Macmillan and Co.*

A.D.—*The centrifugal pump does not know whether its axis is horizontal or vertical, and its efficiency will be the same in either case, other things being equal. The height to which the water would be lifted if the pump had an efficiency of 100 per cent., would be that due to the velocity of the circumference of the revolving wheel in feet per second, or* $\frac{v^2}{2g}$, *which means the square of the velocity, divided by 64·2. But the efficiency will be less than 100 per cent., and the lift will be less in proportion. A good wheel has been found, with a circumferential velocity of 37ft. per second, to carry a head of 18·21ft., instead of about 21·5ft., the theoretical column. Very good pumps will carry a 90 per cent. column. It is understood that there is no discharge. Your pump would carry a theoretical column of about 8ft. If it carries 7ft. in practice its efficiency is very high, about 87·5 per cent*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

**** The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, April 16th, at 8 p.m. Paper: "Telephone Exchanges and their Working," by Dane Sinclair, member. Discussion.

ROYAL INSTITUTION OF GREAT BRITAIN.—Thursday, April 16th. Afternoon Lecture: "Recent Chemical Progress," by Professor Dewar, M.A., LL.D., F.R.S., M.R.I. Friday, April 17th, at 9 p.m. Paper: "Colour Photography," by M. G. Lippmann.

THE INSTITUTION OF MINING AND METALLURGY, LONDON.—Wednesday, April 15th, at 8 p.m. Paper: "Transmission of Power by Compressed Air at the North Star Mine, Grass Valley, California," by Mr. P. R. Robert, member.

CLEVELAND INSTITUTION OF ENGINEERS.—Monday, April 13th, at 7.30 p.m. Papers: "The Economical Utilisation of Waste Gases from the Blast Furnaces," by Mr. Archibald S. Keith. "Electric Tramways," by Mr. Phillip Dawson, C.E.

SOCIETY OF ARTS.—Monday, April 13th, at 8 p.m. Cantor Lectures: "Precious Stones," by Professor Henry A. Miers, M.A.—Lecture I. Wednesday, April 15th, at 8 p.m. Paper: "Early English Organ Writers," by Burnham Horner. Dr. E. H. Turpin will preside.

THE SOUTH STAFFORDSHIRE INSTITUTE OF IRON AND STEEL WORKS' MANAGERS.—Saturday, April 11th, at 7 p.m. Paper: "Suggestions on the Report of the Delegation, organised by the British Iron Trade Association, on the Iron and Steel Industries of Belgium and Germany," by Mr. H. M. Punnett.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 14th, at 8 p.m. Papers: "The Thirlmere Works for the Water Supply of Manchester," by Mr. G. H. Hill, M. Inst. C.E. "The Vyrnwy Works for the Water Supply of Liverpool," by Mr. G. F. Deacon, M. Inst. C.E. Friday, April 17th, at 8 p.m. Paper: "Recent Developments in Lighthouse Engineering," by Mr. Nicholas G. Gedye, Stud. Inst. C.E. Mr. W. T. Douglass, M. Inst. C.E., will preside.

ROYAL METEOROLOGICAL SOCIETY.—Wednesday, April 15th, at 7.30 p.m. Papers: "Mean Amount of Cloud on each day of the year at the Royal Observatory, Greenwich, on the average of the fifty years 1841 to 1890," by William Ellis, F.R.S. "Atmospheric Dust Observations from various parts of the World," by E. D. Fridlander, B.Sc. "Analysis of the Greenwich Rainfall Records from 1879 to 1890, with special reference to the Declination of the Sun and Moon," by Major H. E. Rawson, R.E., F.R. Met. Soc.

THE INSTITUTION OF JUNIOR ENGINEERS.—Friday, April 17th, at 8 p.m. Paper: "Dredgers," by Mr. Walter J. Hunter, member. Synopsis: I.—General considerations in designing dredgers. II.—A short description of the various classes of dredgers. *a.* Bucket ladder dredgers. *b.* Hopper dredgers. *c.* Other classes of dredgers: (1) sand pump, (2) grab, (3) pneumatic, (4) land, (5) spoon barges, (6) other dredgers, (7) unloading apparatus. III.—*a.* Description of a dredger built for the Peruvian Corporation. (1) Vessel, (2) machinery—boiler, engines, driving gear, bucket ladder, top and bottom tumblers, buckets, shoots, ladder hoist gear, crabs, &c.; (3) cost of dredging. *b.* Description of a dredger built for the Leeds and Liverpool Canal Co.: (1) considerations in designing the hull, (2) vessel, (3) machinery—boiler, engine, driving gear, stern delivery, &c.; (4) cost of dredging. The paper will be illustrated by diagrams.

SOCIETY OF ENGINEERS.—Monday, April 13th, at the Royal United Service Institution, Whitehall. Paper: "The Water Supply of Small Towns and Rural Districts," by Mr. Percy Griffith. Synopsis: Scarcity of published matter relating to—Points of difference between large and small works—Ownership by local authorities—Facilities for purchase—Advantages and disadvantages of municipalisation—Supply by meter *v.* supply by rate—Application of meter system at Abingdon and Malvern—Reasons for success—Borehole pumps *v.* well pumps—Improvements in pumping machinery—Matthews' system of running small pumps at high speeds—Riggs' high-speed pump—Pearns' outside packed ram—Halstead Waterworks Extensions:—Description of well-sinking, pumping machinery, reservoir, &c.—Godalming Waterworks:—impounding reservoir—Cost of pumping by means of gas engine—Oil engines for pumping purposes—Description of works at Blandford, Fenny-Stratford, Swanland and Sonning—Results of tests showing costs of pumping—Appendix statistics of thirty small waterworks.

THE ENGINEER.

APRIL 10, 1896.

THE LAST MEETING OF THE INSTITUTION OF NAVAL ARCHITECTS.

WE have been told that the last meeting of the Institution of Naval Architects was a great success. We have been assured that it was a remarkable failure. Both statements contain some truth. Both represent a misapprehension of the facts. All depends on the sense in which the words failure and success are used, and this again turns on the conception which is formed by the individual expressing an opinion as to the object, scope, and functions of the meetings of this or any other society. If the purpose of the council is to get together a number of papers to be read, and overflowing audiences to hear them, then the last meeting was, like most of its predecessors, an unqualified success. If, on the other hand, the object had in view is the advancement of naval architecture and things cognate, then we fear it will have to be admitted that the meeting was a failure. It was a failure not so much because the papers were not good in themselves, as because they were not suited to the situation; it was a failure because those present did not utilise the papers. It will be instructive, we think, to elucidate this proposition a little in detail.

The papers read may be divided into two classes—the practical and theoretical. In the first we shall place two already reproduced in our columns on water-tight doors in bulkheads. Both were excellent of their kind, but the audience quite failed to take any advantage of that excellence. The naval officers—the admirals—had it all to themselves. Colonel Soliani's paper was scarcely mentioned. Lord Charles Beresford's paper was used as a text not for a discussion on bulkhead doors and their construction, but for an attack on the Admiralty by one party and its defence by another party. The two sides would hear of no compromise. The one cried, "away with water-tight doors altogether;" the other said "we cannot do without them." Positively not one word was said or heard about bad and good methods of constructing such doors. No engineers or shipbuilders had a word to say on the point. A couple of inventors managed, indeed, to squeeze a word in edgeway, but they might just as well have been silent. There can be no doubt but that the reading of these two papers was a waste of time. Everything that was said could equally well have been said if the president had tossed to the meeting as a subject for discussion, "Have we too many water-tight doors or not in the bulkheads of her Majesty's ships?" A couple of hours were expended in discussing this point. But the impartial observer will ask, What possible effect will all this have on the construction of our men-of-war? And the answer must be simply that it will have no effect at all. Now it seems to us that Colonel Soliani's paper deserved a better fate. It is certain that we must have such doors. Surely an expression of opinion as to bad and good methods of construction is before all things about them desirable. There are at least half-a-dozen different systems of working such doors in use. Which is best? It was a remarkable fact that some 300 gentlemen—engineers and shipbuilders and shipowners and naval men—could sit quietly and express no opinion nor supply the least scrap of useful information on this subject. If it is true that there was nothing to be said, then why select such a subject for discussion? If, as we believe is the fact, a great deal remains to be said, and said with advantage, why was the discussion permitted to take the turn it did, leaving the important issues entirely unnoticed. The speakers being all far more anxious to win a dialectical success than to advance knowledge, the proceedings were appropriate to a debating club rather than to a representative scientific assemblage.

It may be said that naval officers talked about the points that most interested them, and that not being engineers, they left constructive details untouched. This is true so far as it goes. But the naval officers left Mr. Kinghorn's excellent paper on salvage appliances severely alone, and so did everyone else. The discussion simply collapsed; no one seemed to be disposed to say anything about it. Are we to assume that the subject was not sufficiently important? Perhaps not. It remains, then, to say that it was not suitable to the audience; but it would be very difficult, we think, to prove this. There must have been many persons present who knew a great deal about the subject, and yet preferred to keep silence. Thus, then, we find that the discussion on two very practical papers broke down. As regards the first, as we have said, the speakers ignored the paper and ventilated their opinions on a single point. As regards the latter, no one took the trouble to speak at all. But we may go through the whole list and find that, without any exception, the discussions were poor and inadequate. Take, for example, Mr. Seaton's paper, which we give in full this week. It bristles with points for debate. Such a paper read before the Iron and Steel Institute, for example, would most probably have been followed by an exhaustive discussion, in which eminent metallurgists and steel makers would have taken part. We have gone carefully over the report of the discussion. We give in another place its gist. We have done our best to pick out all that was worth reproducing in our pages, and we ask our readers what it all amounts to? Pages will be occupied by it in the "Transactions." Will the utterances of the speakers modify in the slightest degree future practice? Will, for instance, the fact that Mr. Manuel uses shafts so large that, according to Mr. Seaton, they might just as well be of cast iron as of forged steel, induce Mr. Seaton or anyone else to reconsider his practice and put in bigger shafts? Is it at all likely that Mr. Manuel thinks that cast iron would do just as well as wrought steel? Was any human being the wiser after the discussion than he was before?

The waste of time was appalling, and we confess we do not see how waste can be avoided in future. According to the rules of the Institution, no one should speak for more than ten minutes without the express permission of the meeting. But according to its practice, every one who stands up to speak spends a large portion of the ten minutes in a more or less personal laudation of the writer of the paper; and this, although as often as not he occupies the rest of the time in tearing the writer's arguments into shreds, and in telling the meeting that the paper is a mistake from first to last. It should be a rule of the Institution that laudation should be taken as understood; much valuable time would be saved in this way. But nothing causes such waste of time as the so-called reading of mathematical papers; every one knows that these things cannot be read aloud with any advantage. It is equally well known that they cannot be discussed with any benefit except by those who have read them carefully, and then even if such persons are present and speak, the bulk of the audience entirely fail to comprehend what is going on. All such papers should be taken as read, and printed in the "Transactions," with such written communications in the way of discussion as may be approved by the council or secretary. We have more than once said that we think three-day meetings once a year in London are a mistake; but the greatest mistake of all is to attempt to crowd into these three days work for six. Take Professor Watkinson's paper, or lecture rather, on water-tube boilers. A whole morning sitting might have been devoted to that lecture alone with advantage, instead of the fag end of one evening. There is no due sense of proportion about regulations which permit of such arrangements being made. There is reason to believe that either the Council do not attach much value to discussions, or that they are unable to find adequate speakers. But surely an improvement could be effected. We can call to mind papers and discussions which were in all respects everything that could be desired; but the papers were specially intended to be discussed. In effect it seems to us, and to many others as well, that the Institution attempts too much, and that a smaller number of better papers—better from the point of view of the conditions under which they are used—would give more satisfactory results. The discussing power of the Institute requires cultivation and development. The Institution of Naval Architects has done such excellent work in the past that its performances are judged by a very high standard; it has a considerable, if not great, reputation to live up to. We have criticised the Council, but the Council cannot accomplish impossibilities, and unless the general body of members exert themselves to make the proceedings of the Institution valuable, failure must be the result. Improvement is needed in many respects, in none more than in the proportions and conduct of discussion.

"IF THE COLLIER KEEPS THE PEACE."

This phrase was recently used by the director of one of the largest steel concerns in Sheffield, and repeated by two others this week. It expresses picturesquely the unrest at present disturbing industry in view of an anticipated renewal of difficulties in the coal trade. It is proverbially a foolish policy to meet troubles half-way, but this kind of trouble has got to be met more than half-way. It has got to be faced. The meetings already held of the Conciliation Board show an acute cleavage between coalowners and coalgetters, as represented on the one hand by the masters' executive, and on the other by the miners' leaders. The position of the coalowners may not appear to superficial observers to differ from that of the colliers. Both express a desire for the continuance of the Conciliation Board for another couple of years, but each wants it in a different way. The position taken up by the Miners' Federation is simplicity itself. "We want," in effect, says Mr. Benjamin Pickard, M.P., "recognition once for all of the principle of a minimum and a maximum wage." These are not his exact words, but they appear to be the practical outcome of them. Nor does he insist so strenuously upon a maximum wage as upon a minimum. Mr. Pickard's contention all along has been that wages should never go below what he calls a "living wage." What the "living wage" precisely is, and how it is always to be secured, has not been explained. But Mr. Pickard leaves nobody in any doubt as to what he sets down as the minimum wage. He desires the rate of miners' remuneration to be fixed on the present standard—that is, retaining the 30 per cent. advances on 1888. It is here that the coalowners come into issue with him. They point out that since the arrangement which terminated the coal war of 1893 the value of coal has gone down very considerably, and that the wages now being paid are not only in excess of what that value admits of, but are actually in excess of the rate paid in other and competing districts. For example, the seaborne coal, which comes from Northumberland and Durham, has the advantage of cheap water carriage to the metropolis. This enables the northern colliery proprietors practically to command the bulk of the London market. They have the further advantage that their miners are receiving from 10 to 15 per cent. less in wages. Outsiders may ask why it is the northern miners consent to take so much less than their brothers in the Midlands. The answer is easy enough. The northern coalfield is not bound by the decisions of the Miners' Federation, and the miner being free to follow the bent of his own inclination, he regards wages as the amount of money taken home at the week end, and not the amount per ton he receives for his labour. The Yorkshire, Derbyshire, Notts, Lincolnshire, Leicestershire, Warwickshire, Cheshire, and Lancashire miners are content to take an extra amount per ton for their output and work less in the week. It thus comes about that the coalfields of England present the singular spectacle that in the districts where the rate of pay is highest the week's wages are lowest, and in those where the rate of pay is lowest the week's wages are highest. The inevitable issue of it all is that while northern collieries are doing fairly well, the Midland collieries are doing very badly. It is stated, and believed to be true, that only one colliery in three in the Midland district is paying. In many cases the pits are being continued at a loss, a policy which, of course, can only last for a certain time, and there are many collieries where the machinery is simply being turned round without any gain whatever. All this can only have one end. It has already had its ending in the case of most of the small collieries, not a few of which have gone to the wall, and others are rapidly drifting that way. Every day it becomes more and more apparent that the work of the future is to be in the hands of the great coal concerns, such as are now opening practically virgin coalfields under conditions which admit of vast output at a low price. There are coalowners in the Midland district who are concerned both in the old style of collieries and in the new. It would be hard to find any of the old collieries where any hope of profitable work is entertained. The eyes of the owner, even in that case, are fixed upon his new collieries, where mechanical appliances are as perfect as can be procured, and the man indeed is elbowed out of the pit as much as possible by the machine. All these things do not make for the benefit of the miner, and the coalowner frankly tells him so. But the miner is loyal to his Union. All that he says is this—that to-day, though working less than he used to do, he is getting more money for it; and this seems to fit in with the humour of the majority of the Midland miners. There is, of course, an intelligent minority who hold with their brethren in the North that the wage is not what one gets per hour or per ton, but what one takes home at the week end. But then that is not the policy of the Unions, and the men themselves cling to the present condition of affairs in the hope that somehow or other they will yet have a full week's work at the full wages they are now receiving. They never believe—they are counselled not to believe—what coalowners state about losses made down the pits, and they blame the coalowners themselves, thus again following the argument of their leaders, for the low values obtained for coal as due entirely to the keen competition between coalowners for the orders in the market. Mr. William Parratt, one of the ablest of the Yorkshire miners' agents, stated very plainly at Barnsley, on Thursday, that if coalowners would agree that coal should not be sold below a certain price, they would be "black sheep" who sold below that price, "and the men would help them to punish the black sheep by stopping their pits and not allowing them to work until they repented of their error, as the men would go in heart and soul for keeping up prices and wages." From such utterances as these and other signs, it is quite clear to-day that there is danger ahead. The Miners' Federation say now, as they said in 1893, "No Reduction." What is more, they demand that under no circumstances whatever shall there ever be a reduction below the present rate. They interpret the proposition of the employers as meaning practically the establishment of a sliding scale which shall regulate wages according to values. Outsiders regard that as a sensible solution of the problem, but the miners' leaders take a diametrically opposite view. They candidly declare that they have done with the law of supply and demand. They hold that instead of values regulating wages, wages in future shall regulate values. Nor do they merely hold that doctrine. It has been cordially endorsed by the various lodge meetings throughout the Midland districts, and those here and there who dissent are as the voices of a few crying in the wilderness. That is where the difficulty is greatest. Coalowners say that they cannot continue unless the cost of output is reduced, and there is only one way left to reduce it, and that is in regard to wages. The miners' representatives put their backs to the wall and practically say—"You can help yourselves if you please. You can stop cutting each other's throats in the market, and get better prices for your product. Under any circumstances we are not going to work to let you give your coal away, and we will submit to no alteration which means less money per ton than we are now receiving." The various miners' lodges are to be "ballotted" on this point. No one who knows the coalfield can doubt what the answer will be. They will follow their leaders, and the coalowners will be face to face with the old difficulty of carrying on their industry under conditions which prevent profit, or of engaging in a fresh conflict to enforce concessions which are voluntarily refused. Things, it is to be hoped, will not come to the worst, but if a great calamity is to be averted there will have to be a much clearer and brighter understanding between both parties than there seems any prospect of while this is written.

THE GREAT MAP OF THE WORLD.

The idea of constructing a map of the world on a very large scale has long been a favourite one with geographical and other learned and scientific societies both at home and abroad. Some four or five years ago the matter was seriously and energetically discussed at an important international Congress which met at Berne. For some time the project was held in abeyance, but has recently been revived with encouraging prospects for its future execution. Although we have termed the scale a very large one, it may not perhaps appear to be so when it is stated that it is to be a natural scale of one millionth. This is equivalent to nearly 15¾ miles to the inch, which, supposing the two hemispheres to be projected on the same plane, would make the map 100ft. long. While the general consensus of those who have studied and investigated the subject appears to be nearly unanimous with regard to its ultimate value, yet it is admitted that many and grave drawbacks—we will not call them objections—exist with reference to its present practical adoption. It is the same with the proposed new map as with any other novelty of merit, improvement or reform which modify, and even sometimes completely subvert previous ideas, habits, and methods of accomplishing the same results. There must always be, more or less, a wrench when the change does come, and the proper course to adopt is to render the pressure as light and as bearable as possible. It must be borne in mind that English people, as a rule, are averse from change, though by no means averse from progress. On the contrary, they are in one sense the most progressive people in the whole world; but they prefer to make the advance and to progress in their own way, and they are also perfectly well aware that "change" is not always a synonymous term with progress.

It may not appear at first sight that there is anything particularly novel or interesting in the construction of a map of the world on a scale hitherto unattempted. Nor is there; but in connection with the project there are some attendant changes and results to which we propose to call attention, which may materially affect the subject of international time and the interests of navigation and navigators. Among these the principal are, the unification of a prime meridian, combined with a new reckoning of time and a uniformity in, at least, linear measure.

Were we disposed as a nation to regard this subject from the purely selfish point of view, we could afford to do so with more justice than the majority of our neighbours, but the interests of science and of international relationship would be at a great disadvantage if cold water were thrown upon the discoveries, inventions and industries of other people, together with their practical applications, by those who were not so immediately affected by any proposed novelty. It is well known that our meridian of Greenwich does not fulfil all the conditions desirable for so important a starting point, which could moreover be ensured by the selection of a new and universal departure. Nevertheless, at the congress held at Washington in 1884, twenty-two of the States represented there were in favour of the adoption of our meridian. Among other reasons, it was alleged, on the score of economy, that at the time the great majority of marine charts and maps were delineated with the degrees of longitude, commencing at Greenwich. No actual resolution was arrived at, because neither France nor Brazil would give their adhesion to it. Admitting for the moment that the expense—which would be very large—of providing new maps and charts, instruments, timekeepers, and other appliances indispensable to the adoption of a different zero of longitude, would be justifiable, and would in the long run repay the outlay, there are other considerations which, if they do not exactly militate against the proposed alteration, have fair claims to be heard on the other side. In 1882 the number of charts printed for the Royal Navy, the Government, and the general public was 230,000. It is very questionable with regard to astronomy, for instance, whether the meridional unification would be altogether a boon. In England, France, Russia, and other principal nations the initial meridian passes practically through the chief observatories of those countries. This coincidence is particularly favourable in making many celestial observations, and very much facilitates the working out of the arduous and difficult calculations and valuable series of tables for which we are indebted to the able astronomers stationed in different parts of the world. Again, it is extremely doubtful whether the establishment of a fresh zero of longitude would lead to a corresponding alteration in the general reckoning of time. As it is, with the exception of Greece, the greater part of the central and southern countries of Europe have already committed themselves to the adoption of a time which would not indicate noon at any of the meridional localities suggested as preferable to those already in use. Nearly all the principal European Powers have virtually given their adhesion to the recognition of the time of Central Europe, and the division of the day into twenty-four hours. The railway stations in Italy have recently employed clocks with dials which show both the old and new hourly notation. Our readers will probably recollect that some years ago attempts were made to introduce the twenty-four-hour dials in watches and clocks here. Some were purchased, possibly more from curiosity than any other motive, but the movement fell through.

More than two centuries ago Hierro, one of the Canary Islands, was put forward by the French geographers to receive the honour of being selected as the *locale* of the first meridian, but since it was reckoned as exactly 20 deg. west of Paris, its individuality was merged in that of the French capital. As a suitable zero of longitude its fame dates as far back as 140 B.C., when it formed one of the "Fortunate Isles," which was the title given by the ancients to the present Canary Islands. The Arab geographers had also reckoned their longitude from the same locality. One of the recommendations put forward in its favour at the Congress of Washington was that it did not traverse the site of any established observatory, and that its anti-meridian passing through the antipodes possessed especial advantages from a terrestrial point of view. Previously to the Assembly in America, the Seventh International Geodetic Congress held at Rome had pronounced in favour of the unification of the longitude and hour with those of Greenwich. Apart from other considerations, the economical reasons for adhering to the English first meridian are enormous. Even the opponents of the present, or perhaps we should say, the advocates of another datum point, admit the value of the existing maps and charts referring to, and based upon the Greenwich zero, and that it would require an outlay of over a couple of millions to replace them by substitutes. The production of the proposed map itself, in the number of proof sheets necessary to complete the total, is estimated at about a quarter of a million. It will be some time yet before, in the supposed interests of international science, geography, and astronomy, we shall have to shift our meridian in coincidence with that of the Canary Islands.

◆◆◆

THE MERSEY AND IRWELL JOINT COMMITTEE.

Mr. R. A. Tatten, M. Inst. C.E., presented his annual report at the meeting of the Joint Committee of the representatives of the County Councils and County Boroughs of Lancashire and Cheshire, held on the 30th ult. It is a voluminous document, and deals very fully with the work accomplished since the Committee was constituted in October, 1891. Within the district under the jurisdiction of the Committee are seven county boroughs, with a population of 1,148,674, and a rateable value of £5,214,252; eleven boroughs, population 294,277, and a rateable value of £974,411; sixty-two urban district councils, population 127,914, rateable value £867,623. On the Irwell the population numbered 998,625, and number of works 272; on the Isk the population numbered 297,217, and number of works 44; on the Medlock the population numbered 261,981, and number of works 18; on the Mersey the population numbered 633,496, and number of works 60. The report states that the practice of cinder-tipping direct into the rivers or on the banks, so that the floods carried them away, had been practically stopped, and the river beds were consequently improved. The Ship Canal dredgings now included comparatively few cinders. The number of works to prevent pollution in operation under urban and rural authorities had increased from twenty-seven to fifty-two, while those under construction had risen from eight to thirty. Orders of Court to cease pollution had been obtained in thirty-eight cases in Lancashire and Cheshire, and two in Derbyshire. The progress made by manufacturers had been greater than by local authorities. The good result on the Irwell was noticeable, while the Mersey lagged behind. Generally speaking, Lancashire was in advance of Cheshire in the improvement effected. This was partly due to the fact that some of the tributaries flowed from Yorkshire and Derbyshire into Cheshire, and were polluted before entering the latter county. In Yorkshire a Rivers Board was constituted in 1894, and had not yet got into working order. The Joint Committee are waiting to see the result of the action taken by Yorkshire. Derbyshire refused to send representatives to the Committee, and it was hoped that the County Council would take measures to deal with pollution, but as they have held back, action must be taken. In common fairness to those persons who have been compelled to spend money, their competitors must be brought under similar regulations. As a rule, the manufacturers had met the Committee in a fair spirit, although to many the cost of constructing works had been very considerable. Sir Henry Roscoe was reappointed chemical adviser to the Committee for a period of twelve months.

THE INCREASED YIELD OF THE BLAST FURNACE.

The enlargement of the output of the blast furnace of late has been more than once referred to, but usually the illustrations have been of single furnaces only. The facts allowing of a comparison on a large scale, however, are obtainable now, and they may be stated briefly. In the North-Eastern district in 1878 there were 94 blast-furnaces at work in July, and the output of these furnaces was 166,603 tons, or just about 1772 tons for the month of 31 days. In January of this year, in the same district, there were also 94 blast-furnaces in operation, but the production was enlarged to 269,195 tons, or roughly, 2863 tons per furnace for the month of 31 days. In other words, there has been on the average an increase in the output of the furnaces in the district of about 1091 tons in the month—that increase being the work of eighteen years. It is partly to be traced to the greater use of the hematite ores. In the earlier year there were only 17 furnaces engaged in smelting iron from these imported ores; but in the later year there were no fewer than 42. But it is also traceable in some considerable degree to the furnaces being of larger average capacity now, so that the work is done in a numerically smaller smelting plant; and probably it is effected in an area that is less, for the furnaces a score of years ago or so were dispersed over a large part of the North, and included many furnaces that were old and in some degree antiquated. In the renovation and renewal of the furnace plant in the largest of our iron-producing districts, there has, however, been not only the rebuilding of stacks of larger dimensions, but there has also been the employment of every resource of the metallurgist and the engineer that could be expected to add to the yield of the furnace, and hence it is that there is now traceable much of that rapid increase we have above shown. Nor is there any finality as yet attained in the average yield of the furnaces, for it is well known that furnaces of larger dimensions, and driven more powerfully, are being now employed, and that experiments in regard to the form of the plant are also being tried, so that there may be expected a further increase which has yet to be tabulated. But there is not now so rapid an enlargement as there was of the use of hematite iron ores, though no reduction of the proportion is to be anticipated, as far as can be seen.

A CORNER IN ENGINEERING MATERIAL.

We are accustomed to hear of pools and syndicates in various departments of the iron trade of America; the pig iron trade in different parts of the Continent is often subjected to the same treatment, and it is known that the steel rail combination of British makers has lately been re-formed. It is rather, however, a novelty to find that an attempt has been made to corner engineers' material, but such is the nature of the newest European ring. The story reaches us this week from France of the establishment of a strong combination designed to sustain prices in the interest of the mill owners. We learn that across the Channel twenty-three makers of structural iron and steel have completed an arrangement by which they undertake to deliver all their product to a central company in Paris. The new company is to be sole purchaser. No one is permitted to carry out orders of third parties. Only the requirements of the French State Department—army, navy, &c.—are excepted. On the other hand, the syndicate agrees to provide for the sale of the products, and therefore buys the entire output of the different works for subsequent re-sale. Each of the works is allotted a certain tonnage. No member is allowed under any circumstances to have orders given by the syndicate carried out by any other member of the syndicate, either by exchange or special arrangement. The sales territory of the syndicate is divided into a certain number of zones. The general assembly decide every month what the selling price for each zone shall be, and at the same time also determine the price at works at which the different plants must deliver the base sizes to the syndicate. The contract between the twenty-three works and the central organisation has been concluded for five years. Combinations of this sort tend to raise the price of iron and steel. But in all probability the ordinary healthy competition of the French works outside the ring, combined with that of English and German firms, will be too much for it.

LITERATURE.

Elementary Treatise on Electricity and Magnetism, founded on Joubert's "Traité Elémentaire d'Electricité. By G. C. Foster, F.R.S., and E. Atkinson, Ph.D. Longmans, Green and Co. 1896.

The authors originally intended merely to translate the French work introducing such small modifications as might seem to make it better adapted to English needs. But on further consideration they thought it desirable, while adhering to the general plan of the original, to introduce into it that view of the nature of electrical phenomena which was originated by Faraday and developed by Maxwell in his classical treatise. The adoption of this idea has necessitated the re-writing of several chapters, and it will also be found that a somewhat greater knowledge of mathematics is assumed on the part of the reader than is necessary for the comprehension of the original work. The earlier chapters deal with frictional electricity, difference of potential and induction, and are very clearly written. Chapter V. deals with "General Theorems," and here the authors explain the properties of tubes of force. These theorems are made use of in Chapter VI., which deals with "Electrical Capacity and Condensers."

The elementary nature of the work appears to have been forgotten here, as the differential calculus is used, the authors having departed widely from the simplicity of the original work. What is the use of pointing out to a young student that "The value of the integral $\int \frac{de}{s}$ which occurs in this expression depends on the size and shape of the tube, &c." All he can do is to skip the entire chapter. We fear that the same remark applies to several other parts of the work, and that it will tend to diminish its usefulness for junior classes. In the chapter upon frictional machines the authors work out the power of a double-plate Holtz machine, and conclude that it was for this particular machine 1·06 watts, or 1·06 joules per second.

Dealing with cells, the authors discuss the question as to whether the difference of potential between the plates is due to the action at the separating surface of the two metals—which may be termed the contact theory—or to the action between the metals of the surrounding air—which may be termed the chemical theory—but they do not decide this difficult question, and consider it impossible of solution. In the chapter upon thermo-electricity, a useful table is given which the authors call a thermo-electric diagram, due to Professor Tait. If the nature of the two metals is known, and also the respective heat of the junctions, the electro-motive force of the couple can be read off. For example, the iron-copper couple with one junction at 50 deg. and the other at 250 deg. gives 2000 microvolts.

The chapter upon magnetic induction is well written, and gives the results obtained by Professor Ewing. The authors refer to Professor Lodge's work, and in their chapter upon lightning conductors sum up the results of recent work by stating that the most certain way to protect a building from the effects of lightning is to encase it in a metal network in perfect conducting communication with the earth. We fear that it will be some time before architects and their clients will be induced to go so far as to afford such perfect protection as this to a building. Although the work is probably above the heads of elementary students, the authors have succeeded in putting forward the physical aspects of electricity and magnetism in the light of the most recent discoveries.

Practical Trigonometry, for the use of Engineers, Architects, and Surveyors. By Henry Adams, M.I.C.E., Professor of Engineering at the City of London College. Whitaker and Co. 1896.

This is likely to prove a very useful book, especially to young surveyors, in guiding their first timid steps in the mystery of Trigonometry. The usefulness and indispensability of the subject is shown by a few well chosen practical applications worked out completely by means of sines or cosines, or the equivalent co-ordinate steps, North and South, East and West. The definitions are given in a more interesting manner than will be found in the ordinary school books. When will mathematical writers begin the natural way of counting angles, like time, starting from 12 o'clock? At present they always start at 3 o'clock and work backwards on the clock face. The addition formulas are quoted without demonstration, but in most of the applications the trigonometry of one angle is found sufficient. In explaining the use of logarithms the author should point out that four-figure logarithms are sufficient for most practical purposes; this table as an appendix would form a very useful addition, not occupying more than four pages.

Elasticität und Festigkeit. Von C. Bach. Berlin: Julius Springer. 1894. 16s.

This is a treatise on the strength and elasticity of the materials, steel especially, which are employed by engineers. The first edition appeared in 1889, and the author, from his position as professor of mechanical engineering in the Technical High School of Stuttgart, is well qualified to act as an exponent of this subject. The diagrams are very well chosen, and a notable feature of the book are the photographic reproductions of the testing of various typical specimens and forms of material. In the mathematical part the author displays a commendable restraint; he does not choke off the practical man in search of useful information by a tropical jungle of unnecessary analytical formulas. The treatment of the difficult question of the strength of a flat plate exposed to pressure, such as the flat end of a boiler, may be instanced as a specimen of the author's best method. Under the severe requirements of modern engineers in quick-running machinery and marine work the designer cannot afford to be ignorant of the most modern developments of theory as prepared for immediate application.

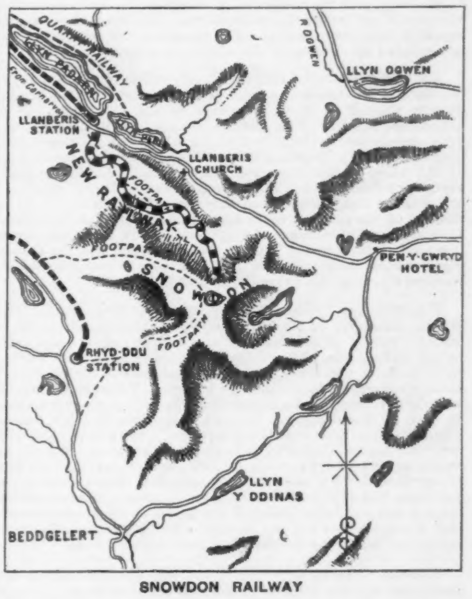
ROLLING MILL ENGINES FOR THE DOWLAIS WORKS.

The illustration on our double-page represents one of two pairs of geared rolling mill engines as constructed by Messrs. Daniel Adamson and Co., Engineering Works, Dukinfield, near Manchester, for the Dowlais Iron Company, for the new steel works lately established on the seaboard at Cardiff. Both pairs of engines are exactly similar in design and construction, and only differ in the sizes of their cylinders; the smaller pair put down being used for driving the slabbing mill, having cylinders 48in. by 60in. stroke, whilst the larger pair, now illustrated, are used for driving the plate mills, and have cylinders 54in. diameter by 60in. stroke, both engines being geared to the mill shafts by gearing having a ratio of two to one. As will be noticed, the design of the engines generally is in the direction of providing ample strength and proportions for the heavy and intermittent strain to which they are subject. Some idea of the strengths and proportions adopted in the engine under notice will be formed when we say that the gearing is in cast steel, having teeth of the double helical form, and shrouded on both sides up to the pitch line, the pinion wheel being 5ft. 8¾in. diameter, 9in. pitch, and 30in. broad on the working face, whilst the second motion wheel into which the pinion gears is 11ft. 2⅝in. diameter, the second motion shaft being of forged steel, having bearings 24in. diameter; and the crank shaft also of forged steel, with bearings 22in. diameter; the crank and crosshead pins are also of the same material, and respectively 10½in. and 14in. diameter, whilst the piston rods are 9¾in. diameter. The total delivered weight of these engines is about 280 tons. The chief feature, however, in these engines lies in the novelty of the valves and gear adopted, which are of the patent and improved Wheelock type, of which Messrs. Daniel Adamson and Co. are the sole manufacturers in Great Britain, it being one of their specialities. The general arrangement of these valves, as shown in section in our illustration, embodies the principle and adoption of valves and seats of the flat grid type, giving multiplicity of opening, ample areas, and small frictional movements. Both steam and exhaust valves are contained in one chest at each end of the cylinder, the seats of the valves being in the form of a plug turned to fit the cylinder, the chest of which is bored a little tapering for this purpose; at the same time the valves and their seats, being separate parts from the cylinder itself, can be constructed of specially hard and durable iron; thus spare valves and seats can be kept in stock, and all wear on the cylinder dispensed with; the valve shells or plugs, being in duplicate, enables one to be withdrawn for examination or replacement in the minimum of time and stoppage. It will also be noticed that the whole of the valves are placed immediately underneath the cylinders, with direct ports and passages, so that it is impossible for the water of condensation to collect in the cylinders or passages, as it drains away naturally. The whole arrangement of the valves and gear is extremely compact and perfectly accessible in every part. The reversing gear is of the Allen straight link type, and is worked by hydraulic power controlled from the driver's platform, the driver's platform being arranged at such a level as enables the driver to clearly see the mill floor; another feature is a somewhat special arrangement of the reversing and handling gear, which is in duplicate, the platform being so arranged that the engines can be handled from either side, it being the ultimate intention to put down mills on each side of the engines, and for which the necessary clutches are provided.

We may say, in conclusion, that the engines have now been at work some time, and have given every satisfaction, and have fully justified the claim of the makers that the arrangement of valves and gear as adopted is the most superior and economical for the purpose. Messrs. Daniel Adamson and Co. have also supplied the whole of the boiler plant and receiver range, supplying steam for all purposes to this most modern example of steel works.

THE ACCIDENT ON THE SNOWDON RAILWAY.

As our readers are generally aware, a very regrettable and fatal accident occurred on the Snowdon Railway on Monday. A train consisting of an engine and two carriages, followed by a second train composed of an engine and one carriage, safely ascended the mountain by noon. In descending, however, about one mile from the summit the engine of the first train mounted the rails near or at the curve which is seen in one of the engravings we publish on page 371, where it leaped the rails and tumbled down the slope. The brakes were immediately applied to the carriages by Mr. Oswell, the resident engineer of the line, and Mr. Aitcheson, the manager, who stuck to their posts, and called on the passengers to keep their seats. The brakes acted at once, the carriages came to a standstill, and the passengers alighted. Unfortunately, one passenger, despite the warning of his friends and of Mr. Aitcheson, jumped over the low side door—the sides of the carriages being open—and struck the rock; he broke his legs, and has since died. Another passenger jumped, but he was only slightly hurt. After the passengers had alighted, the second train, which is supposed somehow to have been signalled by the first engine striking a wire in falling, came on. The driver, perceiving the carriages of the first train at a standstill ahead of him, put on the brake, but the engine came into collision with the carriages, which it sent off the road, but itself remained on the rails.



SNOWDON RAILWAY

The driver and stoker of the engine which went over the slope both jumped from it and saved themselves almost unhurt. There were eighty-three passengers in the first train, all of whom were almost unhurt, except the two who jumped off. The permament way is, we learn, not in the least damaged. The safety of the passengers is probably due to the method of working. The engines are not coupled to the train, but in going up simply push the rear carriage, and in descending allow the front carriage to push it. The carriages being provided with ample brake power are thus unaffected by any defect in the working of the engine. A general description of the railway was published in The Engineer, vol. lxxix., from which we reproduce the accompanying plan, showing the route and position of the line. The photographs which we reproduce on page 371 have been taken for us by Mr. R. C. Symons, of Llanberis.

No. 1 is taken from a position looking up from the derailed carriages towards the scene of disaster. It shows the starting place where the engine run away, viz., at the place where an engine and carriage is seen standing in the distance. The engine left the rails and tumbled over, where the group of men in white trousers are standing in the near distance, a little to the right, and behind the telegraph post. No. 2 view is taken from the point where engine left the rails. Looking down from this it will be seen that the line is not damaged, and in the immediate foreground is the spot where the engine turned over. View No. 3 is from the front of the derailed carriages looking up over the embankment, a nearer view than No. 1. View No. 4 shows the derailed carriages.

On Wednesday at the request of Sir Douglas Fox, the engineer of the line, Major Marindin, on behalf of the Board of Trade, visited the scene of the accident, but the line being private property, the Board has no power to hold an inquiry.

RAILWAY MATTERS.

The Cambrian Railways Company have decided to reduce the first-class fares over the whole of its system to 1½d. per mile for single tickets. It is understood that the alteration will be effected in time to give summer visitors the full benefit of the reduction.

In the current session twenty-two tramway Bills, constructing nearly 103 miles, and proposing capital to the amount of £2,353,200, are being promoted. As compared with 1895, the number of Bills shows an increase of sixteen, and the capital proposed an increase of £2,116,146.

A general classification of the accidents on American railways in February last gives the following:—Defects of road, 6; defects of equipment, 27; negligence in operating, 22; unforeseen obstructions, 17; unexplained, 57; or a total of 129. Of these no less than 91 were derailments, and 42 of these were unexplained derailments.

Rapid progress is being made with the extension of the Liverpool Overhead Railway to the southern extremity of the city, and it is expected that by the end of August the line will be so far completed as to provide for the direct conveyance of passengers from the Dingle to Seaforth. The railway at present terminates at the Herculaneum Dock, and to bring the Dingle into connection there will be 250 yards of iron viaduct and 800 yards of tunnel, both built for double line.

According to an official statement of revenue and expenditure for six months ending December 31st, 1894 and 1895 respectively, on the West Australian Government Railways, the miles opened were 550. The revenue to December 31st, 1894, was £132,818, and for 1895 £214,286, or an increase of £81,468, or over 60 per cent. The expenditure was £77,094 in 1894, and £108,960 in 1895, or an increase of £31,866, or 41 per cent. The expenditure per cent. of revenue fell from 58·04 to 50·84.

An attempt to wreck a train was discovered early on the morning of the 1st inst. on the Manchester, Sheffield, and Lincolnshire line, between Sheffield and Doncaster, just in time to avert the disaster. Near Conisborough two blocks of limestone, each weighing about a hundredweight, were found on the rails, and further on a third obstruction of a similar character was found. Fortunately, a goods driver noticed the stones, and warned the nearest signalman in time to enable him to stop an approaching passenger train.

An unusual accident occurred on the London and North-Western Railway main line, between Lancaster and Preston, and near to Garstang Station, on Tuesday, to a goods train from Carlisle, which included a wagon laden with heavy machinery consigned to Blackpool. The weight caused the spring of the wagon to give way, with the result that it caught in the chairs supporting the metals, and before the accident was discovered about a mile length of chairs were broken. The damage to the permanent way necessitated the conduct of the traffic over a single line.

An important development in connection with the purchase of the tramway system of the metropolis by the London County Council is likely, according to the *City Press*, to be announced shortly. Negotiations, it says, are in progress, and have already reached an advanced stage, for the formation of what may be termed a Tramway Trust. This trust will acquire a lease of the whole of the tramways, and pay to the Council a yearly rent, to be determined. The movement has the hearty support of the existing companies, whose directors realise that it is the best solution of the problem to be found; and it is also understood that amongst the members of the Council there is a general consensus of opinion in its favour. Wonder when will the Council carry out the work entrusted to it, and cease to constitute itself a business scheming and promoting concern.

Writing on "Co-operation by Rail and Road," Mr. H. M. Kennedy, of Plumpton, says:—"Cumberland should be among the first of the counties to use light railways and automotors on its roads. The centre of the arable area with which I have to do is nine miles from the nearest railway station, though three broad-gauge lines bound the triangle. To make the coming transits pay, co-operation is essential. To such movement we hope to have an impulse given by Lord Winchilsea and Mr. Horace Plunkett, from whom visits are expected. We now pay £400,000 a day for imports similar to those produced at home. The bill for butter and margarine exceeds £45,000 per day, and that for eggs is nearly £73,000 a week. By co-operation, facile transit, and judicious technical instruction, these enormous imports can be greatly and profitably reduced and home products substituted." Mr. Kennedy does not say in what way "judicious technical instruction" is to bring about any of these desirable ends.

A new railway was completed last summer along the west coast of Italy from a junction 45 miles south of Naples to Reggio, nearly opposite Messina, in Sicily, a distance of 227 miles. The approach by rail to Sicily heretofore was made by going nearly due east across the peninsula, 169 miles from Naples to Metaponto, on the instep of the boot, and then following the sole of the foot south, southeast, and finally around the toe northward a little way to Reggio, 267 miles further. The time required was 21 hours, which was some hours longer than the steamer voyage between Naples and Messina, and naturally even the comfort of a Pullman sleeping car, which was attached to the through train, attracted few passengers, especially as the fare was nearly 16 dols., to say nothing of the sleeper. By the new line the distance of 272 miles between Naples and Reggio is made in 13½ hours. The *Railroad Gazette* says there is a Pullman car, as before, and the cars are ferried across the straits, only a few miles below Scylla and Charybdis, to Messina. The construction of the new line has extended through many years, and has been very costly. There are about 100 bridges of considerable size on the line, and 82 tunnels, one about 3 miles long, one 2¾ miles, two about 2 miles, and fifteen more from ⅝ to 2 miles long.

The Great Northern Railway Company has just completed at its Doncaster Plant Works two new first-class and third-class dining cars, which have been sent on a trial trip from Doncaster to Retford, thence to Newark, Grantham, and Nottingham, returning in the evening to Doncaster. The cars, which excited much interest *en route*, ran with perfect smoothness, there being nothing to choose in that respect between the first-class and the third. The first-class dining saloon is 55ft. 6in. long; the length over platforms, 62ft. 0½in.; extreme length over vestibules, 64ft.; extreme width, 9ft.; extreme height from rails, 13ft. 4in. The car is carried on two six-wheeled bogies, and weighs 36 tons 19 cwt. The saloon compartment is a model of elegant appointment and comfortable arrangement, and all the accessories in lavatories, kitchens, &c., leave nothing to be desired. A special feature is Gould's patent vestibule, continuous platform, buffer, and automatic coupler. By this means the cars are joined together, and the passenger can walk from one end of the train to the other. The third-class dining car has a length in body extending to 64ft. 5¾in.; the extreme length of the vestibule, 69ft. 9¾in.; extreme width, 9ft.; and extreme height from the rails, 13ft. 4½in. This car is also carried on two six-wheeled bogies, and fitted with the Gould patent vestibule, &c. The appointments of the third-class are so complete that there seems practically little difference betwixt the two. The furnishing, fittings, lighting, illumination, and heating being on the most sumptuous and elaborate scale, both for third-class and first-class passengers. These cars, which are believed to be the largest in England, are to be used on the Leeds and London service, commencing this month.

NOTES AND MEMORANDA.

New South Wales produced in 1894, 452,756 cwt. of sugar, and 1,573,886 gallons of molasses.

From the experiments described in a paper on the "Origin of the Röntgen Rays," by M. Jean Perrin, the conclusion is drawn that the Röntgen rays are developed only at those points where the kathode rays are arrested, and that this is true whatever material may be used for the tube.

The number of letters passing through the New South Wales Post-office in 1894 was 67,993,400, of which 11,125,500 were for places beyond the Colony, as were 9,503,900 of the 41,667,300 posted during the same period. In 1855 the number of letters and newspapers—inland and foreign—was about 2,000,000.

The *Revue des Sciences*, in the course of an article on aluminium, gives some very striking statistics to show how rapidly the production of it has increased in the United States since 1883, in which year it did not exceed 83 lb. In 1886 the production had increased to 3000 lb.; in 1889, to 47,468 lb.; in 1891, to 150,050 lb.; and in 1893 to 339,629 lb.; while in 1894 the total was 550,000 lb. The *Iron Age* puts the production for 1895 at 850,000 lb., and estimates that this year it will not fall short of 6000 lb. per diem.

A paper was recently read before the Paris Academy of Sciences on "The Invisible Radiations Emitted by the Salts of Uranium," by M. H. Becquerel. A confirmation and extension of previous experiments upon potassium uranyl sulphate. Uranium salts appear to be unique in the length of time during which they give off photographically active rays in the dark. On comparing the rate of discharge of a gold leaf electroscope by the radiations from a crystal of potassium-uranyl sulphate and a Crookes' tube respectively, the effect of the tube was found to be, *Nature* says, over one hundred times greater than that of the crystal.

A paper was recently read before the Paris Academy of Sciences on "The Mechanical Action proceeding from a Crookes' Tube," by M. J. R. Rydberg. On repeating the experiments of MM. Gossart and Chevallier, it was found that the actions observed on the radiometer had their origin in the well-known layer of positive electricity with which the external antikathodic surface of the Crookes' tube is covered during the discharge. By covering the radiometer with a metallic gauze screen, it is possible to take Röntgen photographs through it, without any rotation or mechanical effect being observable.

A means of communicating to the *x* rays the property of being deviated by the magnet, is described in a recent number of the *Comptes Rendus*, by M. A. Lafay. A bundle of rays from a Crookes' tube was allowed to imprint on a sensitive plate the shadow of a platinum wire supported on a very thin sheet of silver. When the whole was placed in a powerful magnetic field—400 C.G.S. units—the reversal of the current produced a sensible deflection of the image, if the needle was strongly electrified by being placed in connection with the negative pole of the induction coil. If the needle was not electrified, no sensible deflection of the image could be produced.

M. Eugene Fariot, an engineer of some repute and a worker in aëronautics, one of the siege aëronauts who escaped from Paris in the Louis Blanc, died recently at the age of sixty-eight. *Nature* says he has bequeathed a sum of £4000 to the Société Française de Navigation Aerienne, of which he was a member. One half of this sum is to pay the expenses of experiments, and the other half to be funded in the name of the society; the interest to be expended yearly on its behalf. Consequently, it is expected that an end will be put to the long stagnation in scientific aëronautics in France, owing to the indifference of the public authorities for an art so popular in that country. The result shows the wisdom of the authorities.

Mr. J. H. McConnell, in a recent paper before the Western Railroad Club, made some interesting comparisons of rolling stock of to-day and of twenty-five years ago. At that time a large portion of the traffic was handled by 16in. by 24in. cylinder locomotives, and the maximum load for a freight car was 20,000 lb. To-day cars of 60,000 lb. capacity are common, and sometimes they reach 80,000 lb. The latest refrigerator cars when fully loaded weigh as high as 100,000 lb. The early cars carried 300 bushels of grain; the modern cars carry 1000 bushels. The early sleeping cars weighed 60,000 lb.; the modern sleeper weighs 100,000 lb. The 30-ton engine has grown to weigh 60 tons; the ten-wheel engine has increased from 45 tons to 90 tons; and the consolidation from 50 to 80 tons. An 1870 engine weighing 100,000 lb., and carrying 140 lb. of steam, hauled 24 loads, weighing 582 tons; the 1895 engine weighs 150,000 lb., carries 180 lb. steam pressure, and hauls 35 loads weighing 1120 tons over the same division. Twenty-five years ago, with a time schedule of 22 miles an hour, it would have been considered an impossibility to make an engine haul ten cars on a schedule of 40 miles an hour; yet it is now done every day, and these engines maintain a speed of 55 miles per hour between stations, with ten cars.

On February 6th, Mr. Morris R. Sherrerd, of the Newark, N.J., Board of Public Works, in conjunction with the officials of the East Jersey Water Company, made some experiments on the carrying power of mains. The main selected was the 36in. branch to the high-service supply, and in preparation for it the water in the South Orange Avenue reservoir in Newark was drawn down 3ft. Observations were taken at eight points. The normal pressure of the 48in. line at Belleville was increased from 70 lb. to 84 lb., and at the South Orange Avenue end of the 36in. main from a normal pressure of 20 lb. to 28½ lb. The test was continued for one hour, and during that time the 36in. Venturi meter readings showed an average daily flow of 22,500,000 gallons under the contract requirement as to height of delivery, which in this case was measured by pressure. The 36in. main is 25,000ft. long, and the pressure under which it delivered the 22,500,000 gallons would be equivalent to a grade of 2·4ft. per 1000ft. Previous to the test the average daily draught through the 39in. main was 11,000,000 gallons, and the highest 16,000,000 gallons, or 6,500,000 less than the actual capacity. The test showed the actual capacity of the 48in. main to be about 35,400,000 gallons in twenty-four hours. The *Engineering Record* says the 48in. conduit was designed for a delivery of 50,000,000 gallons, and the 36in. conduit for 25,000,000 gallons in twenty-four hours.

The cost and the difficulties of transport in Persia are great and curious. Not long ago the cost of transport from the port of Bushire to Shiraz and Ispahan rose to four times the ordinary rates, and it fluctuates violently at short periods. Recently the main cause was a mortality amongst horses, mules, and donkeys in the south of Persia. They died along the road of murrain, and their bodies were left by the wayside, tainting the air and the grazing, and so increasing the epidemic. A constant source of disturbance to transport is the travelling of local officials. They all require a large amount of carriage, and their messengers are sent into the bazaars and the surrounding country to impound all the animals they can get. The muleteers object, as their animals are overloaded and ill-treated, while they get no adequate hire, are kept away from their homes for indefinite periods at their own cost, and are abused and beaten by the great man's hirelings. The system of seizing baggage animals is called "*Mal bigiry*," and when it becomes known that it is intended, the muleteers flee with their beasts to the hills and hide. Those who are on the road leave their loads at the nearest village and disappear to some place for security, so that for a fortnight or more it is quite impossible to get any animals, for until the muleteers know that the place has returned to its ordinary state they will keep away. In consequence of the frequency of this disorganisation in the south of Persia, Manchester goods which reached Isaphan by the Persian Gulf now go by Baghdad, Kermanshah, and Hamadan—a longer and apparently more expensive route.

MISCELLANEA.

The new battleship about to be built at Devonport will have engines developing 15,000 indicated horse-power with forced draught, with which it is estimated that the vessel will attain a speed of 18·75 knots.

The Royal Agricultural Society will offer prizes for self-moving vehicles for light and heavy loads such as have commonly to be carried by farmers and others dealing in farm and dairy produce, but not for passenger vehicles, the trials to take place in connection with the Manchester meeting next year.

The Admiralty, says the *Army and Navy Gazette*, have directed that in future the torpedo boat destroyers are to be subjected to a two hours' steam trial after commissioning, and before leaving port for service each vessel is to attain a mean indicated horse-power of at least nine-tenths of the engine-power guaranteed by contract.

The Sheffield City Council, at its meeting on the 8th inst., decided, by 29 votes to 14, to advance the Borough Surveyor's salary from £800 to £1000. At a recent meeting the Council refused a smaller advance to the Medical Officer of Health, who has consequently become a candidate for the post of Medical Officer of Health for the West Riding.

The first-class barbette battleship Benbow is to undergo an extensive refit at Devonport. Her masts will be lengthened to give greater signalling facilities at sea; her ten 6in. breech-loading guns will be replaced by ten quick-firers, and hand-loading arrangements will be fitted to her heavy guns. The cost is estimated at about £5000. She is to be completed by the second week in May.

At a meeting of the Manchester City Council on the 1st inst., the report of the Corporation Committee charged with the Ship Canal affairs was received and adopted. The report contained a number of statistics relating to the Canal, and concluded by recommending the Council to levy a special rate of 14d. in the pound to defray interest on the money raised by the Corporation on behalf of the Canal Company.

A collision took place on the 1st inst. on the Mersey, resulting in the sinking of a Dock Board dredger. The dredger ran into the Isle of Man steamer King Orry while the latter was at anchor in the river. The steamer was only slightly damaged, but the dredger sank in a few minutes, the crew being thrown into the water. All were rescued, after an exciting scene, by the steamer's boats and Customs launch.

His Honour Judge Ellison, of the Sheffield Court, who died suddenly in London on the 7th inst., was umpire between the Yorkshire coalowners and colliers in the great wages dispute of 1879. His award was in favour of the men, his Honour holding that they were then receiving barely a decent maintenance, and considering the nature of the work, he held that the coalowners had not made out a case for reduction in the area covered by the arbitration. The miners' leaders regard Judge Ellison's ruling as the forerunner of the principle of a living wage.

In connection with the Crystal Palace International Horse-drawn and Horseless-Carriage and Roads Locomotion Exhibition to be opened on May 2nd, by the Lord Mayor, there will be a chronological collection of cycles from the earliest times, marking the birth, rise, and development of the cycle—1818-1893. Those in possession of and willing to lend specimens are requested to communicate with Mr. H. Hewitt Griffin, Putney, giving full particulars of tyre, maker, and exact date manufactured. Only distinct types are required. The carriage of specimens to and from the Crystal Palace will be paid by the Crystal Palace Company.

After reaching the depth of 400ft. at Messrs. Eastman's, Latimer-road, a copious supply of water has been tapped after passing through the following beds, viz.:—Made ground, 12ft.; ballast, 18ft.; blue clay, 124ft.; mottled clays, 47ft. 6in.; black pebbles and sand, 6ft.; brown and red sand, 4ft.; green sand, 23ft.; flints, 1ft.; chalk and flints, 164ft. 6in. Total 400ft. Mr. William Whiteley's well is 600ft. deep at West Kensington. Messrs. Crosse and Blackwell, Soho-square, and Messrs. Welford and Sons, Elgin-avenue, Maida Vale, are having similar work carried out by Messrs. C. Isler and Co., who are also engaged to do similar work for the Hastings Corporation and the Wolverhampton Corporation.

The telephone service between London and Paris has been so successful that the postal authorities are about to lay a second cable across the English Channel, to meet the increasing demands for the use of the wires. The work on the land wires is now being proceeded with on both sides of the Channel. The second cable is to be laid from Lydden Spout, about two miles to the west of Dover. The land wires of the present system terminate at St. Margaret's Bay, from which point the cable starts. For the second cable, the English land wires will branch off from the old line to the north of Folkestone, and be continued across to the cliffs. It is stated that when the second cable is laid, Manchester and Liverpool and some other large centres are likely to be directly connected.

It is proposed to hold another Milling Exhibition next year in the Agricultural Hall. A writer in the *Miller* says:—"Milling engineers never felt less like exhibiting than to-day. The cry is that orders are just now as wary and shy as the African gorilla, and until that state of things alters for the better, it would be useless to look for anything like support of a milling exhibition. It is beside the mark to point to the successful Exhibition of 1881, as at that day the conditions were altogether different. There was then a comparatively large amount of virgin soil to be worked, whereas now the requirements of our millers have to a great extent been met. Again, in 1881 roller plants on any system were rarities, which, in general, proprietors were not over anxious to exhibit. For that reason the milling engineers of that day were willing to go to considerable expense in erecting more or less complete plants in the Agricultural Hall. But nowadays, with roller mills of all capacities scattered over the kingdom, the conditions are altogether reversed. What inducement is there for engineers to play at installing machinery on scaffolding more or less rickety, when, for a railway fare of a few shillings, any miller can see the same plant under the best conditions?"

A Bombay firm, Messrs. W. and A. Graham and Co., are constructing gigantic iron tanks for the storage of petroleum oil upon the Port Trust reclamation at Mody Bay. The consumption of kerosine oil in the Bombay Presidency has become more and more extensive; and the idea occurred to Messrs. Graham and Co. to import the oil in large tanks, and without shifting the tanks, to remove the oil into other tanks and reservoirs on the bunder, to fill small tins with it, and put them in the market for sale like the tins at present imported into the city. For that purpose four large round iron tanks are being constructed on the reclamation, each of which is 35ft. in height, and 64ft. in diameter, capable of holding 2500 tons of oil. Round the four tanks will be constructed a stone wall with the object of gathering in the leakage from any of the tanks. An underground store-room will also be provided, so that in case of fire or accident the oil might be poured into it. A wooden jetty, 200ft. long, will be erected, alongside which the steamers will be placed; and by means of pipes the oil will be transferred from the tanks on board into the firm's tanks on shore. A "settling tank," 17ft. in diameter, is also to be constructed by means of which the oil will be filtered and purified before being put into small tins for the market. Either the above dimensions are wrong or the 2500 tons is given by the Indian contemporary from whom we quote, instead of about 1500 tons.

LETTERS TO THE EDITOR.

(*Continued from page 372.*)

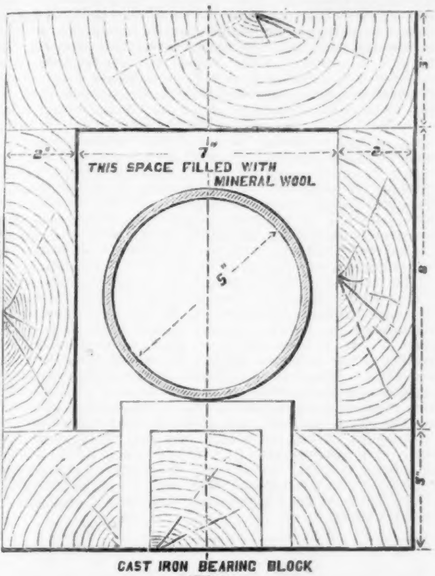
INSULATING UNDERGROUND STEAM PIPES.

SIR,—In your issue of February 21st you print a paper by R. C. Carpenter on "Methods of Insulating Underground Systems of Steam Piping." To me, all these methods appear to be good examples of how "not to do it." So far as my experience goes, it is impossible to make any wooden conduit that will keep tight. Place a section of any of the wooden conduits Mr. Carpenter describes in an ordinary steam-heated room, and in a few weeks you will find it full of season cracks. It is clear that the case will be worse when the interior of the conduit is exposed to steam heat and the outside is in contact with the earth, and I have found that when the spring thaws occur these conduits leak like baskets, and water is always running through them into the boiler room.

Cement or tile conduits can be kept tight, provided they are properly laid on solid ground. In most cases such conduits have to pass over some made ground, and are liable to crack from settlement. In such cases under drainage will not prevent them from leaking. Such conduits are also objectionable, because it is very difficult to get at the pipe, except where split tile is used. It therefore appears to me that no conduit can be considered perfect unless we know that it will at all times be water-tight, in spite of slight settlements.

I once had to convey steam underground for a low-pressure gravity-return system of steam heating. The conditions were unfavourable, as the main had to slope toward the boiler-room, and local conditions made the maximum depth to top of casing 3ft. 6in., and for part of the run the depth was only 2ft. 8in. This, too, was in a situation where the prevailing wind seldom permitted the snow to become over 5in. deep. The outside temperature is frequently – 20 deg. Fah., and occasionally drops as low as – 40 deg. Fah. The pipe had to pass over several fills caused by previously laid sewerage and water systems. For about five weeks in the spring when the "break-up" is in progress the ground is covered with several inches of slush and water.

To meet these conditions I designed the conduit as in Fig. 1. The lumber was all edged and quite dry. A trough was built in 14ft. sections, with halved joints 1ft. long. To insure rigidity the bottom joints were located 2ft. from those in the side, and all the joints were firmly screwed together after the conduit was lined up. It has been my experience that in cases like this roller bearings are of little account, since we have no guarantee that they will operate after the pipe has been in use for some time, and the roller journals have become rusted, or stick from the gumming of the oil. I therefore discarded rollers, and placed under each pipe coupling a cast iron chair, Fig. 2, which is faced on top, and allows the pipe to slide easily. This plan has been used for years by one concern which employs many hundred feet of 12in. pipe carrying steam up to 160 lb., and in no case has trouble developed.



CAST IRON BEARING BLOCK
FIG I
SECTION THROUGH CASING

To insure tightness the following plan was adopted:—Makers of planished copper can supply sheets which are slightly defective in the tinning, and have to be sold as scrap. We purchased sheets of this copper, 14 oz. and 16 oz. weights, in widths of 11in. and 41in., riveted and soldered similar widths end to end, then turned up the broad width into a trough 11½in. wide. This was first put into the trench, the wooden trough was then lowered into it, the work was then lined up, the pipe was next laid, and then the trough was filled to the top with mineral wool loosely packed in place. The wooden cover was then secured with 5in. screws, the 11in. copper was next rolled along the cover, and the joints along the top edges of conduit were then carefully soldered. The metal covering was carried through the walls of the buildings at each end of the pipe line, and pieces of copper soldered to the casing were flushed into the outside face of the walls.

To guard against any chance of the pipe getting out of line by reason of decay of the wood, the chairs were provided with two lugs, Fig. 2, which passed clear through the bottom plank and rested directly on the copper, and beneath the latter a large flat stone was carefully bedded into the earth. The chairs were secured to the plank to prevent any motion and the consequent wear on the copper. Where fills were encountered care was taken to put a bearing stone and cast chair on each side of it, so that any deflection of the conduit could not affect the pipe. The soil was very gravelly, so that no under drainage was provided, and it is questionable whether such drainage would ever be necessary with a conduit like this. A conduit like this can stand a great deal of distortion without any harm. As to its insulating qualities, I may say that it has been in use several years, has given perfect satisfaction, and at no time is there any external evidence that the pipe line exists. I have never been able to detect any escape of heat through melting of snow over the trench. Cost of the work was as follows. Cost of pipe and laying, mineral wool, and excavating trench are not included, as they form no part of the conduit proper:—

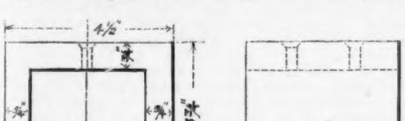


FIG. 2
BEARING BLOCK UNDER COUPLINGS
FACED ON TOP

Length of conduit	142ft.
	Dols.
Copper smith, 2¼ days, at 4·00 dols.	9·00
Steam fitter—lining up—1¼ days, at 4·00 dols.	5·00
Three labourers, 1¼ days, at 1·50 dols.	5·63
Carpenter, 9 days, at 3·00 dols.	27·00
Solder, copper tacks, and rivets	2·20
4 grs. 5in. No. 20 wood screws	5·72
1 grs. 2in. No. 14 " "	·06
1350ft. white pine at 17 per m.	22·95
520 lb. tinned copper scrap at ·11	57·20
135 lb. castings at ·03½	4·73
Carting	1·50
Total	141·09

Or about 1 dol. per lineal foot. No charges are made for stone-bearing plates or for planing chairs. Lathe work was done in our shops by students. We had left from a new building some stone which we had no other use for, and were glad to get rid of it by putting it under the conduit.

Mr. Carpenter describes a conduit consisting of a tile pipe placed inside a wooden casing. To me this seems a wholly mistaken construction. As the wood shrinks and swells it will loosen the joints in the tile. The wood will also absorb water, and be of little use as a heat insulator. It would have been better, I think, to have used a large tile and put the wood casing inside of it. If the tile is properly laid on a sand or gravel foundation and fills are carefully looked after, it can be kept tight, so that the wooden casing will be dry and of some use as a heat insulator.

The conduit I have described permits the pipe to be got at easily. A few minutes' application of the blast lamp is all that is needed to open up the sheathing, and as the screws were dipped in lard and plumbago before driving, they can be easily drawn. If no provision is to be made for opening the conduit, it seems to me that the best form of casing is galvanised spiral-riveted or welded pipe, with proper chairs for the steam main to slide on. Such pipe is made by various firms in this country, and also, I think, by Thos. Piggott and Co., Atlas Works, Birmingham, and Mechan and Sons, Glasgow. If the steam pipe is properly covered, and the work is made tight at the beginning, it will stay so, and in the end save money for its owners.

ENGINE POWER IN PADDLE STEAMERS.

SIR,—I thank your correspondent "J. M." for the particulars of the paddle-wheels of the old and new Flushing steamers. The comparison, although favouring a large diameter of wheel, does not prove that the excessive indicated horse-power required to drive those vessels 21 knots is due to a small diameter of wheel. It certainly is due to an insufficient area of resistance in the wheel race. Given a sufficient area of resistance there, then the nearer the centre of the shaft can be brought to the centre of effort of that surface, the lighter the engines will be, and the less the space they will occupy in the ship. Any error occurring in this area on the small side has usually to be rectified by enlarging the wheels, because there is no room in the boxes to increase their width, and as this increases the moment of inertia, it therefore involves more power to do the same work. Apparent error in this area may be due to a fault in the ship, which makes it more difficult without largely increased power to attain the required speed.

Taking "J. M.'s" particulars of the wheels as they now are—viz., effective diameter 18ft. 6in. (?), float area 124·68 square feet—assume the speed of the wheel 26 knots, ship 21 knots, slip 5 knots. Under these conditions the power at the floats is exactly 6600 indicated horse-power, and, taking the usual efficiency of engines, the power at the cylinders is 7780 indicated horse-power. This is much in excess of what is usually fitted for similar vessels, and yet falls short of the required power by 1200 indicated horse-power. Certainly increased slip would account for this difference, but for a trial obtained in the smooth deep water of the Clyde such slip would be abnormal.

A small diameter of wheel might cause excessive slip, but a badly designed one certainly would; and certainly, after the alterations which have been made on these wheels, the design cannot now be perfect, and a ship designed for a slower speed than that intended would cause still more. This latter seems to be the trouble with these ships, and however interesting and useful the discussion of a small diameter of wheel *versus* a large may be, I submit that we do not have in these ships a practical example by which it can be settled.

R. B. S.

Birkenhead, March 31st.

SIR,—Your correspondents write about big wheels and little wheels. They overlook the essence of the whole matter. The Flushing steamers are far too short for the speed, and that is the reason they require such enormous power. To attempt to drive a vessel less than 500ft. long at anything over 20 knots is brutal.

SPONSON.

Dumbarton, April 6th.

NORTH LONDON RAILWAY LOCOMOTIVES.

SIR,—I see in the book entitled "British Locomotives," by C. J. Bowen Cooke, page 283, that the North London locomotives were designed by Mr. J. C. Park. Surely this is a mistake. Were not these engines originally designed by Mr. Adams, late locomotive superintendent of the London and South-Western Railway, who some years ago was locomotive superintendent of the North London Railway? I think I have seen in Colburn's work on the locomotive that the designer of these engines was Mr. Adams.

April 7th. F. J. P.

[The standard North London Railway locomotive was designed by Mr. Adams.—ED. E.]

BRITISH COAL IN NORTHERN FRANCE.—British coal is one of the largest imports of Rouen, amounting to an average of 400,000 tons a year, while in 1893 and 1894 the import in French ports from Calais to La Rochelle reached 3,500,000 tons. The whole of Normandy and Brittany is largely dependent on our coal for its industries as well as for domestic consumption. The duty is 1f. 20c. per ton.

THE INSTITUTION OF CIVIL ENGINEERS, YORKSHIRE STUDENTS' ASSOCIATION.—The third annual general meeting of the above Association was held in the Law Institute, Albion-place, Leeds, on March 26th. A report of the work done during the past session was read by the hon. secretary, and unanimously adopted. The following gentlemen were elected as officers for the ensuing year:—President, Mr. Arthur Greenwood, M. Inst. C.E.; vice-presidents—Mr. Thomas Hudson, M. Inst. C.E., Mr. A. T. Walker, M. Inst. C.E., Mr. W. H. Bartholomew, M. Inst. C.E., Mr. A. E. Seaton, M. Inst. C.E.; members of Council—Mr. J. Cornock, Stud. Inst. C.E., Mr. J. Duncan, Stud. Inst. C.E., Mr. C. J. Rafard, Stud. Inst. C.E., Mr. E. B. Martin, Stud. Inst. C.E., Mr. R. H. Slade, Stud. Inst. C.E., Mr. F. L. Watson, Stud. Inst. C.E.; hon. sec., Mr. Ralph P. Morrison, Stud. Inst. C.E. A hearty vote of thanks was passed to Mr. W. E. Garforth, M. Inst. C.E., the retiring president and chairman of the meeting, and also to the vice-presidents, and Mr. F L. Watson, the hon. secretary of the Association during the past session.

THE CAUSES OF MYSTERIOUS FRACTURES IN THE STEEL USED BY MARINE ENGINEERS AS REVEALED BY THE MICROSCOPE.*

By Mr. A. E. SEATON, Member of Council.

I SUPPOSE at some time or another every engineer has had personal experience of what are known as mysterious fractures in steel. Their origin and causes have been discussed here and elsewhere, but more often in doing so the question has been begged rather than settled. That there have been an equal number of fractures with wrought iron there is every reason to believe; but owing to its laminated nature the fractures have been small and localised, and seldom of so large and important a character as with steel. I do not propose to dwell at any length on the instances I am about to give, or of others that have come under my notice from time to time of unexpected and, to a great extent, mysterious fractures in steel plates, steel forgings, and steel castings, but rather to direct the attention of the members of this Institution to the researches of Professor Arnold, of the Technical School at Sheffield, who, following the theory and line of argument of Dr. Sorby, of Sheffield, has by many years of constant application and unwearying investigation confirmed them, and demonstrated the causes of the peculiar behaviour of alloyed metals when under mechanical treatment, very notable instances of which were given by Mr. Milton in his paper on copper pipes read before this Institution last year.

The particular case to which I would call attention is the sudden and unexpected total fracture of a steel shaft end, which took place in June, 1895, as shown by the drawing marked A. The shaft in question was made of Siemens steel by a well-known and old-established firm. It was specified to be of "steel containing from 0·2 to 0·25 per cent. of carbon," and its ultimate tensile strength was to be not more than 30 tons, with an elongation of 25 per cent. in 5in. This shaft, in company with the other shafts in the ship, was surveyed, tested, and passed, not only by the owners' representative, but also by the Board of Trade surveyor for the district. There was no indication on the turning of these shafts in the lathe but that the steel was of excellent quality, and, considering that the ship ran continuously from the summer of 1883 until the time of the breakage, there was, judging by the old standards, not much fault to be found; but considering that under close examination a few months before the accident there were no visible cracks or other signs of coming danger, and certainly nothing to indicate such a complete compound fracture as took place close behind one of the collars, several fragments coming out, I think you will agree with me that it is, from an engineering point of view, not satisfactory.

A few years ago both owners and all concerned would have been content with the statement that the accident was probably due to fatigue, seeing that the shaft was so many years old, and had run so many thousands of miles, but I am somewhat sceptical of the fatigue theory, for I fail to conceive how any material, such as mild steel—or, shall I say, soft iron?—can by any application of force, which results in a stress far below the elastic limit of the material, produce any internal change in the structure of the material corresponding with what is shown by the diagram; nor, indeed, do I think that any originally sound structure in which no portion is ever stressed to the elastic limit can give way by what is known as fatigue. I therefore submitted a section of the shaft to Professor Arnold, the nature of whose researches had just previously come under my notice, and I append hereto his report and opinion on the whole matter, to which I attach more importance than anything I have so far said, or can say:—

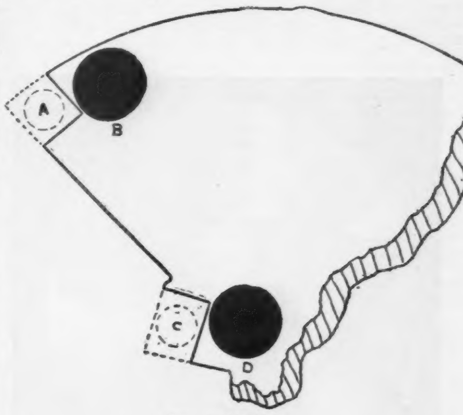

Fig. 1 Half-size

REPORT ON FRACTURED TAIL SHAFT OF S.S. N.

The transverse half-section received was broken into two quadrants. It was noted on fracture that the core of the shaft was very brittle, and showed irregular grey patches, strongly suggesting that the ingot from which the shaft was forged had "piped." The outer ring of steel surrounding the fragile core seemed fairly tough. One of the quadrants was examined chemically and microscopically. It is figured half-size in Fig. 1. The black circular holes B D indicate the positions from which the drillings were taken for analysis, the centres being 3¼in. apart. The areas A C, adjacent to the drill holes, show the position from which the micro-sections were machined.

Chemical analysis.—The figures registered on analysis were as follow:—

Sample B.—Outside of Shaft.

Combined carbon	0·310
Silicon	0·037
Manganese	0·828
Phosphorus	0·058
Sulphur	0·055

Sample D.—Inside of Shaft.

Combined carbon	0·470
Silicon	0·031
Manganese	0·986
Phosphorus	0·167
Sulphur	0·150

The above analyses show most clearly that the ingot from which the shaft was forged must have been cast very hot, and, for an ingot of the moderate dimensions necessary for the size of the shaft, a very pronounced liquation took place. In round numbers the carbon in the centre of the shaft is 50 per cent. higher than that near the circumference. The manganese has liquated with the carbon to some extent, probably in the form of a double carbide of iron and manganese. The phosphorus and sulphur of the core are each three times greater in quantity than at the circumference. It will be obvious that, even taking the mean analysis, the composition of the original steel was highly unsatisfactory as regards purity, and it was also too hard for the purpose intended.

Micrographic analysis.—The results obtained in the microscopic examinations of the sections are of a most instructive character. It will be well to discuss the microstructures under two heads.

(1) *Distribution of the carbide.*—Fig. 2 shows a portion of section C, or the hard core of the shaft, magnified about twenty-three diameters. The gray areas, constituting most of the field, consist of

---

* Read at the Thirty-seventh Session of the Institution of Naval Architects, March 26th, 1896.

iron through which is diffused irregular plates and granules of the double carbide of iron and manganese. A magnification of twenty-three diameters is not sufficient to resolve the irregular laminæ and grains of carbide which will presently be represented in Fig. 3. The dark areas of the micrographs will be hereinafter referred to as "steel." The white areas consist of fairly pure "iron." Remembering that Fig. 2 is a section, it will be obvious on mentally translating it into the solid, that the metal consists essentially of a series of "steel" cells surrounded by irregular and sometimes broken cell walls of "iron," the line of demarcation between the two constituents being very sharp, as will be seen on reference to the next figure. Fig. 3—section C—shows a point towards which the angles of three "steel" cells converge. The magnification is about 170 diameters, which in the present case is sufficient to reveal the irregular laminations of carbide. A structure of this type is always more or less brittle. The sharp junction lines between two diverse constituents are always liable to rupture under vibratory stresses, because the cohesion or adhesion is inferior to that existing between interlocked constituents. Another cause of brittleness in this material is the fact that the metal is approaching "saturation,"† *i.e.*, "steel" is the preponderating constituent, which should never be the case in material about to be employed for screw shafts. Fig. 4 shows the outer shell of the shaft, section A, magnified about 170 diameters. The contrast with Fig. 3 is startling. In the present section it will be seen that "iron" is the "predominant partner," the "steel" crystals being decisively outnumbered; the structure, in fact, consisting of irregular grains of "steel" suspended in a mass of "iron." Notwithstanding this, the structure is not altogether satisfactory, because the junction lines between the "iron" and "steel" are very sharp and definite, with little or no intrusive interlocking. This fault is always well marked in unannealed steel castings, and suggests that in the present case too little work was put upon the ingot in forging the shaft.

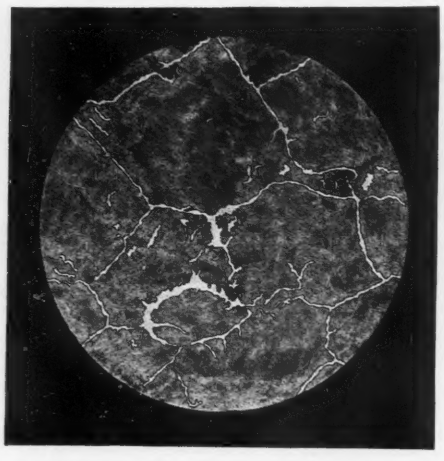

Fig. 2—Section C. Magnified about 23 Diameters. Direct Light

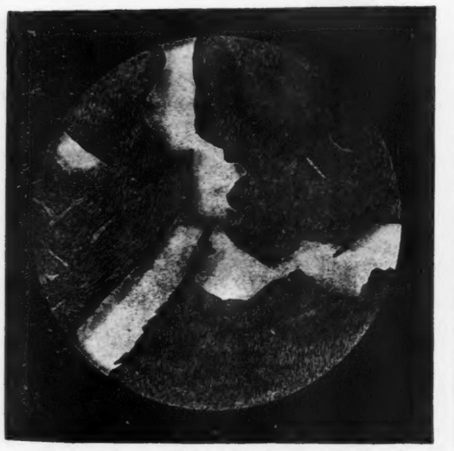

Fig. 3—Section C. Magnified about 170 Diameters. Direct Light

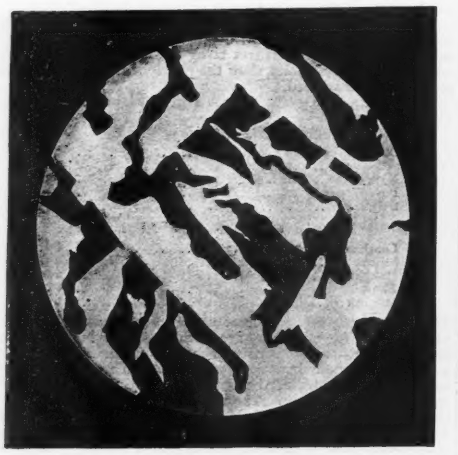

Fig. 4—Section A. Magnified about 170 Diameters. Direct Light

(2) *Distribution of the sulphide.*—Sulphide of iron, even in minute quantity, is readily recognised in steel by the microscope, but it assumes various forms all more or less dangerous to the cohesion of the mass. Its low fusion point causes it to remain liquid or semi-liquid during or after the solidification of the other constituents; and, under favourable thermal conditions, it is capable of producing the most disastrous effects. The distribution of the sulphide‡ in the interior of the present shaft assumes three forms, which are respectively exemplified in Figs. 5, 6, and 7—all section C:—(1) In large isolated globules or irregular masses, Fig. 5; (2) in smaller globules or ovoids forming an irregular train, Fig. 6; (3) in successive elongated streaks: this form is by far the most dangerous, Fig. 7. The sulphide generally, but not invariably, occurs in the iron areas, and its adhesion to the adjacent structure is practically nil; in fact, it is extremely probable that each mass of sulphide is a loose kernel separated by a microscopic fissure from the metal in which it is embedded. Well seggregated masses of sulphide, like those in the shaft under consideration, present, after etching, a hard, smooth sectional surface of a dove-grey colour, surrounded often by irregular brown rings. These may be described as rust, formed subsequently to etching, by the acid which has penetrated the surrounding fissures and which is not removed by the desiccating process to which the samples are submitted. These brown rings are therefore unconnected with the structure, but they serve to throw the sulphide into apparent relief. The sections figured are all transverse, and it is more than probable that an examination of a series of longitudinal sections would reveal the fact that some of the rounded sectional areas are the end views of lines of sulphide similar to those reproduced in Fig. 7, and mechanically equivalent to a series of minute cracks in the interior of the shaft.

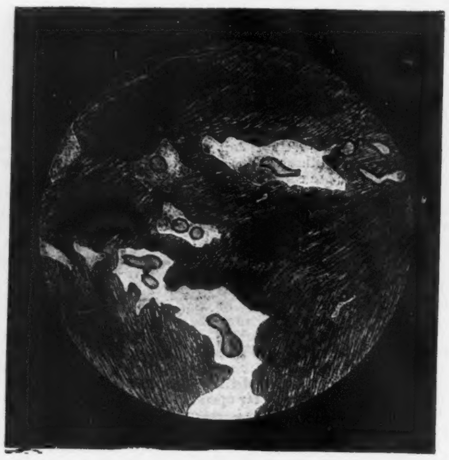

Fig. 5—Section C. Magnified about 170 Diameters. Direct Light

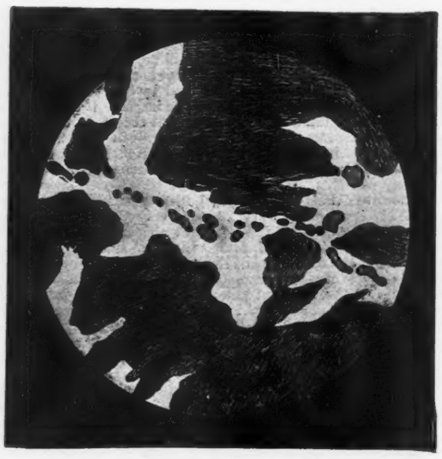

Fig. 6—Section C. Magnified about 170 Diameters. Direct Light

Summary.—It may be stated that the core of the shaft, dealt with in the foregoing report, suffered from several of the most fatal diseases to which steel is heir, namely:—(1) Bad chemical composition aggravated by liquation. (2) Pipe. (3) Unfavourable structural arrangement of constituents. With reference to the influence of the high phosphorus present, it may be stated that the microscopical evidence extant indicates that the phosphide distributes itself like the carbide, but the cohesion between crystals rich in phosphide is very faulty under vibratory shocks. The centre of the shaft, weakened by pipe, carbon and phosphorus hardness, brittle structure, and riddled with sulphide of iron, is little tougher than good grey pig iron. It is almost certain that a number of sulphide flaws in the interior gradually worked outwards along the crystalline junctions of the fairly tough metal outside, until under a vibratory shock of unusual force the whole mass ruptured. The above report is written in ignorance of the circumstances of fracture and of the history of the shaft, and although such knowledge might modify some of the deductions drawn, still, on the whole, the experimental indications obtained from the sections examined are so decisive that I think the conclusions arrived at are substantially accurate.

J. O. ARNOLD.

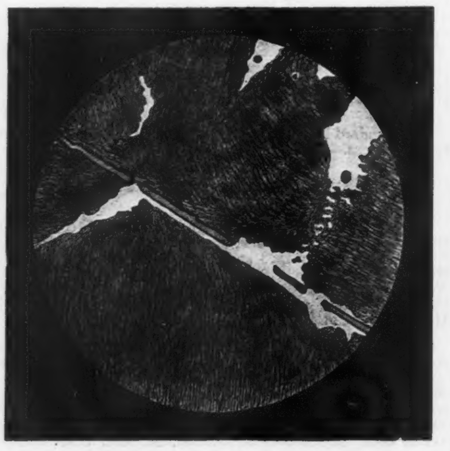

Fig. 7—Section C. Magnified about 170 Diameters. Direct Light

It will be observed that the amount of carbon present, as shown by analysis, is high, in fact much higher than it should have been; but still it certainly is not high enough to account for fracture, and I believe yet that steel with an equal amount of carbon may with advantage be used for shafts. The presence of phosphorus and sulphur is, of course, most objectionable, even in minute quantities; but Professor Arnold has demonstrated to me elsewhere that sulphur may be present to a considerable extent in a steel casting or forging and be of no serious moment, whereas the same quantity may be present in another form and be conducive to most disastrous destruction of the material. The chemist has hitherto only been able to inform us of the quantity of sulphur present; but as to whether in the dangerous or non-dangerous form he is unable to say. In fact, he can throw no light whatever on the subject, beyond stating the composition of the material, and expressing the opinion that, judging by other specimens he has examined, it is possible, and perhaps probable, that the amount of sulphur indicated by his analysis will render the steel unreliable. It seems to me, therefore, that chemical analysis alone is sufficient neither for steel nor for any other compound metal used by the engineer; while, on the other hand, the microscope reveals to us the actual structure of the material, and shows most distinctly whether it is a safe or unsafe one; it is also capable in the hands of an experienced person of practically determining the chemical analysis—certainly it will determine the chemical analysis very much more usefully than a chemist can determine the mechanical properties of the steel he has analysed; so that it appears that the use of the microscope is likely to be of the utmost advantage to the marine engineer, inasmuch as with a little experience, aided by illustrations such as I have shown in Figs. 2, 3, and 4, &c., he can see for himself whether the material he is called upon to use is such as is to be trusted; also to the steel manufacturer it will serve an equally good purpose, and one savouring of that of the skilled eye of the steel caster, whose selections of fractured blister steel enabled Sheffield manufacturers in the old days, as well as to-day, to make with certainty the different qualities of steel required in cutlery, and so establish the reputation of that great and growing place whose progress and enlightenment are so well shown by the splendid means provided by its Technical School for such investigations by Professor Arnold as I have been able to illustrate to you here to-day. I take this opportunity of thanking him for the investigations he has made for me and for his written report, as well as for the illustrations which he furnished specially for the benefit of this Institution.

The result of Professor Arnold's investigations with this particular shaft tends to show the liability of all steel shafts to begin disintegration from the centre, and the fractures and fissures, when commenced, no doubt gradually spread until they reach the surface. It is true that such fractures may occupy only a portion of the transverse section, instead of being spread over the whole. Also that such degradation proceeds without visible indication, and total rupture consequently occurs without warning, and apparently mysteriously. It follows, therefore, that to bore out the centre of a shaft, as is the practice of the Admiralty, which only slightly reduces the nominal strength, really renders it much safer, as it removes that part of the forging which is liable to be of inferior material, and in which disintegration is most likely to commence. In conclusion, I trust that the discussion which may follow will be of more importance, and possibly of more interest than the paper.

THE NOTTINGHAM WATER SUPPLY.—Last week an inquiry was opened at the Guildhall, Nottingham, as to an application made by the Corporation to the Local Government Board for power to supply water to seven rural parishes in the county. The interest in the proceedings was keen, mainly in consequence of the opposition of certain landowners and several public authorities, although the Corporation have, on the other hand, the cordial support of the villages and the Parish Councils who will reap the benefits of an improved water supply. It seems to us, says the *Nottingham Argus*, that the main question has not been considered, whether the Corporation have adopted every means to increase the existing wells and taken measures for the prevention of the present waste. "We are convinced that if the Local Government Inspector had had the assistance of an independent expert water engineer the present application would be postponed for some years," with "a saving to the town of £30,000 in interest alone."

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—At the last meeting of this Association, Mr. Wm. Royal read a paper on "The Manufacture of Crank and Propeller Shafts, and some of the Causes of their Breakage." He described the process of welding up scrap balls, shingling and piling the slabs to form the crank web, and illustrated this by reference to diagrams on the walls. He stated that shafts made of scrap steel were built up in the same way, and considered those preferable to shafts made from ingot steel, which were difficult, if not impossible, to make into sound forgings. The weight of the hammer used is an important factor, as if it is too light the outside of the mass will be drawn or extended until the ends are quite hollow, while if the hammer is well equal to its work, the ends of the forging will be round, showing that the centre is being acted on as well as the outside. When a coupling is forged on the end of a shaft it is advisable to drill a hole up to the depth of the thickness of the coupling, as the metal is frequently hollow and defective there, owing to the drawing of the outside of the mass forming the coupling. Propeller shafts of proper size and best iron, carefully sheathed with gun-metal, seldom give trouble, except from defective fitting of the propeller boss; but if neglected the action of the salt water on the gun-metal liners sets up galvanic action, and sometimes extensive corrosion takes place at the ends of the liners. Steel is not so suitable as iron for propeller shafts, as it corrodes more rapidly, and would have to be lined throughout its whole length, which is practically impossible, as it is difficult to get liners over 7ft. long in one piece. Although these shafts are easier to forge than crank shafts, they are liable to flaws of a very serious character, owing to the contraction of the mass of metal forming the coupling, as the outside cools first and tears the centre open. Another seat of flaws is often found abaft the gun-metal liner in front of the propeller, which may be induced by galvanic action, assisted by the rotation of the shaft, or by the finishing of the shaft under the steam hammer at too low a temperature. The risk in the manufacturing of crank shafts has been greatly reduced by the introduction of built shafts, which have great advantages over forged shafts. The parts being forged separately, can be relied on as being sound. Mr. Royal said a great cause of the breakage of crank shafts had been the presence of the hot well within the foundation plate of the engines, which caused the shaft to be forced out of line by the unequal expansion and contraction of the parts, and mentioned a case where three shafts had broken in two years, and further breakage stopped by planing ⅛in. off the bottom of the two centre brasses, but the best remedy was not to put the hot well in that position.

---

† The saturation point of pure iron and carbon steel is at about 0·9 per cent. of carbon. In steels containing 1 per cent. of manganese it is lowered to about 0·65 per cent. of carbon.

‡ It must be remembered that the 0·15 per cent. of sulphur present is probably equivalent to nearly 1 per cent. of sulphide, which is the substance with which the engineer has to reckon.

MEASUREMENT OF FEED AND CIRCULATING WATER, &c., BY CHEMICAL MEANS.*

By Mr. C. E. **STROMEYER**, Member.

IT is well known that the quantity of air which enters a furnace, or of the gases which pass up the funnel, cannot be accurately measured by any mechanical means, and in all modern boiler trials, where it is desired to estimate the true weight of the waste gases, recourse is had to chemical determinations. A careful analysis is made of the carbon contained in the coal, and of the carbon—in the form of carbonic acid—contained in the waste gases, then by multiplying this ratio into the weight of coal burnt per hour, the weight of the waste products is obtained. This weight is then multiplied into the specific heat, and into the difference of temperature of the air which enters the furnace, and that of the gases which pass up the funnel; and the product is the heat carried away. Complicated though this method may appear, it gives results which are far more accurate than any that can be obtained by direct measurements with an anemometer, and it therefore occurred to me that a similar process, if simplified, might with advantage be applied to the measurement of streams of water not only on land, but also at sea. As will be seen by the experiments detailed in this paper, I have succeeded in measuring both the amount of steam condensed and the circulating water of a marine engine, a task which does not appear to have been previously attempted; the results, too, are sufficiently accurate to compare well with those obtained under more favourable conditions on land engines, in which cases the measurements have always been made by positive and mechanical means.

An inquiry amongst my chemical friends elicited the fact that there are many simple tests for chemical substances, which might be depended upon for estimating them to within one-millionth of the weight of water in which they may be dissolved. The nitrate of silver test for salt—sodium chloride—is one of these, and it was therefore decided to try by this method a preliminary experiment on the feed-water of a marine engine. A measured quantity of salt—sea—water was slowly injected into the condenser of the engine while at work, and subsequently a chemical analysis for salt was carried out, both on a sample of sea water and on a sample of this adulterated feed. Supposing that their salinities stood in the ratio of 100 to 1, and supposing that the rate of injection of the sea water was half a gallon per minute, then evidently 495 lb. of steam had been condensed during the same period, with which the injected sea water had been diluted down to a 1 per cent. solution. 49½ gallons per minute would therefore be the volume of condensed steam.

Measurement of feed supply to land boilers.—The value of such a method of measuring quantities of water will, of course, depend upon the accuracy attainable, not only as regards the chemical tests, but also as regards the whole process. Being unable to make comparative tests by this process as well as by calculated measurement of the feed-water of a marine engine, an experiment was carried out ashore, in which the results could be compared with the readings of a water meter. It is well known that all town waters contain small quantities of salt in solution; in order, therefore, to find the quantity of water which has been fed into a land boiler, it was only necessary to take daily samples, both of the feed-water—town water—and of the boiler water, and to ascertain the relative daily increase of weight of salt in the boiler. Now, although the Glasgow supply, which is considered to be one of the purest drinking waters, contains only between one and two grains of salt per gallon, or about one five-hundredth per cent. by weight, yet the nitrate of silver test is so accurate that it can be depended upon to determine the exact amount to within 1 per cent. In carrying out this experiment I was at first seriously inconvenienced by irregular results, but found that these were due to condensed water in the water-gauge pipe from which the samples had been drawn. In subsequent experiments a cock was fitted direct to the boiler shell, and from that day the readings were regular. The results are contained in a table given by the author. The meter readings were commenced on Monday about noon, and ended on Saturday at about the same time. The town water was constantly running into a large tank holding about 5000 gallons, from which a sample was daily taken for analysis. The feed was drawn from this tank and pumped into two externally-fired boilers, of which the smaller one was worked 9¾ hours per day, while the large one was worked irregularly, sometimes thoughout the night. The respective working hours during the five days of the trial were 48½ and 78¼ hours. Of course, these boilers were under steam for nearly the whole period of 119¼ hours. Another set of samples of water was daily taken from each boiler and analysed. On these occasions the height of water in the gauge glass was noted, as well as the steam pressure, for the salinity of the boiler water had to be corrected on account of the evaporation which would take place during the time that it was being blown into a bucket for sampling. Thus the heat contained in the water while in the boiler would be proportional to its temperature, say 322 deg. Fah. Immediately after leaving the boiler its temperature would be lowered to 212 deg. Fah., and the heat thus liberated would evaporate a certain amount of water, which ought, of course, to be returned to the samples when cold. It amounted to about 15 per cent. The readings of the water level were necessary in order to be able to estimate the volume of water in the boiler, which had also to be corrected on account of the difference of expansion of the boiler and the water within it. Both corrections have been carried out in the table, and amount roughly to 20 per cent. The absolute weight of salt in both boilers could be estimated from the chemical test. It slowly increased from 10,830 grains (= 1½ lb.) to 56,930 grains (= 8⅛ lb.), or from ·006 per cent. to ·032 per cent. As the average saltness of the town water was 1·31 grains per gallon, it required 35,430 gallons to supply the 6⅝ lb.—or exactly 46,100 grains—of salt, and that is the estimated volume of the feed. During this period of 119¼ hours, the water meter recorded 37,270 gallons. The difference, exactly 1840 gallons, may be due either to an error of 5 per cent. in the chemical determination of the feed, equal to one-fifteenth of a grain per gallon—which will be discussed later on—or it may be due to a slight leakage of 30 gallons per day, say 1¼ gallons per hour, which is only ·4 per cent. of the feed supply. It must be remembered that the average saltness of the boiler water is 16 grains per gallon, while the feed only contains 1·31 grains, and a leakage of 150 gallons in five days would carry away 2420 grains of salt, which is as much as would be supplied by the above-mentioned 1840 gallons of missing feed-water. A method which will, under such exceedingly difficult conditions, give a result that is correct to within ·4 per cent., is surely worthy of a more general application. I would, however, wish to point out that, although in this case all the readings and the samples were taken by the boiler attendant, so that it would seem as if this method could be easily applied to land boilers, yet, as there are certain precautions which must be taken to ensure the desired accuracy, I would not recommend it for general use. These precautions are, that the boilers should be filled with fresh water before starting, otherwise the loss of salt due to even small leakages will be excessive; leakages should, if possible, be stopped entirely; and, unless the samples and water gauge readings are only taken on two succeeding Sundays, when there is no steam in the boiler, it will be necessary to make careful allowances for the boiler temperatures, the corrections amounting to about 20 per cent. for a working pressure of 80 lb. per square inch.

Measurement of feed by salt brine injections.—The above experiments were, as already mentioned, undertaken for the purpose of checking the results of some trials at sea, which, it had been vainly hoped, would contain sufficient internal evidence either to confirm or condemn the method. It was believed that the steam weights, as estimated from the indicator cards, would be found to stand in some definite relation to the feed-water; but that no dependence can be placed on them will be evident from a glance at Mr. D. Croll's paper—"Transactions" of the Institution of Naval Architects, 1894, vol. xxxv., page 425—in which, out of seven engine trials, the indicator cards only accounted for from 90 to 67 per cent. of the total steam. In the full power trials of the Research Committee on Marine Engine Trials, which lasted many hours, the variations are even greater, as will be seen from Table II., and in the exhaustive trials which were made by Professor Osborne Reynolds, F.R.S.—"Proceedings" Institution Civil Engineers, vol. xcix., page 194—similar results are obtained.

It is also a matter of everyday experience that the steam weights estimated from indicator cards of different cylinders of the same engine rarely agree, and nobody should be surprised to find that the feed-water measurements obtained by me during very short trials differ from the indicator card readings. The author holds that the results of the experiments which are detailed in tables which we do not give cannot be looked upon as proving the accuracy of the method, but they possess a relative value.

The method of carrying out these experiments was as follows:—

FIG I

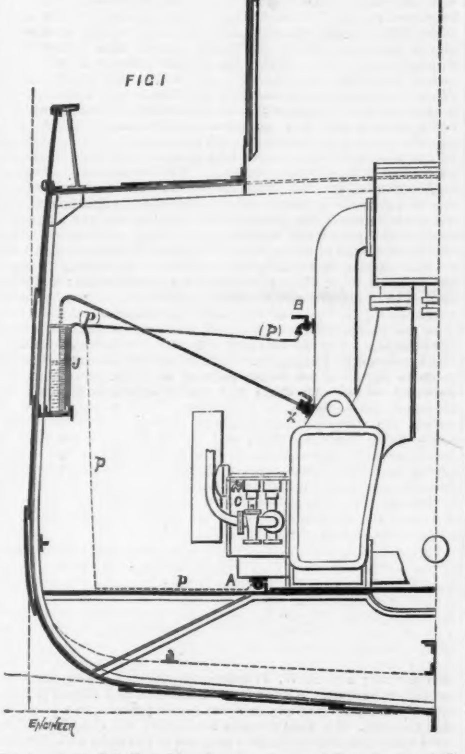

Fig. 1. A small india-rubber hose was connected to a sea cock X, and supplied sea water to a graduated glass jar J; a pipe P, capable of withstanding an internal vacuum, was led from the bottom of the jar J to a special cock A under the air pump. Both the cocks X and A were kept open for about five or ten minutes before each experiment, so that a small but steady flow of water from the sea took place, passing through the condenser into the feed pumps, from which a sample was now taken at the third cock C. A sample of sea water was also collected, and the cock X was then closed, care being taken to see that the jar J was full of water. The suction to the condenser being still open, the water-level in J would sink, and the rate of injection could easily be ascertained by noting the times at which the various marks on J were being passed. The collected samples were now chemically analysed, as will be explained later on, and the estimate of the volume of condensed steam was then a simple matter. Thus, in the case of experiment No. 1, it was found that the sample of feed-water contained 63·3 grains of salt per gallon, while the sea-water contained 1963 grains. The rate at which the condenser sucked the sea-water out of the jar J was 12·68 gallons per hour, and therefore the amount of steam condensed per hour was 12·68 × (1963 − 63·3) ÷ 63·3 = 380·5 gallons. Generally speaking, the process is somewhat more complicated, because of possible leakages of the condenser and priming. To estimate these, preliminary samples of feed and boiler water have to be collected before the injection is commenced. If the former are found to contain salt, corrections must be made which, although they are simple enough, introduce some uncertainty into the calculations, because one cannot depend on the leakages or priming being constant. All experiments with sea-water in which any leakage was detected have been rejected, but in every case samples were taken both before and after starting to inject, in order to be sure that there was no leakage.

Measurement of feed by caustic soda injections.—For this reason, and also because of the possibility which presented itself of also measuring the volume of circulating water, other experiments were made in which the chemicals injected were in one case caustic soda, and, in another trial, carbonate of soda. The results of the caustic soda trials are given in a table. Two jars were used on the trial, one for supplying the condenser and one for the circulating pump; but this arrangement did not work well, except as regards the feed, for which the injected solution amounted to less than three gallons per hour. The supply to the circulating pump could not be maintained at a constant rate, because the jar had to be constantly refilled by jugs, which left no time for accurate observation.

Measurement of circulating water by soda injections.—One of the objects of measuring the circulating water was to obtain a check on the feed-water estimate, which could be done by comparing the heat contained in the steam when it leaves the low-pressure cylinder, with the heat which is carried overboard by the circulating water. The exact amount of heat which is thus wasted has not yet been calculated, but it is evidently less than that contained in the steam when it enters the low-pressure cylinder, but it may be more than the heat contained in the steam at its exhaust temperature. Reckoning from 32 deg. Fah. these two limits are about 1150 and 1130 thermal units. The moisture contained in the steam ought, perhaps, only to be credited with from 130 to 200 thermal units, unless the whole phenomena of moisture in the cylinders can be explained by initial condensation and final re-evaporation, in which case the total feed-water—which includes the moisture—if cooled down to 32 deg. Fah., may be assumed to have parted with about 1140 thermal units. No experiments on this subject have been made on marine engines, and as regards land engines the feed and condensing water are rarely kept separate; and being mixed, they have to be measured together, and even when surface condensers have been used, only the feed which is supplied to the boiler, and not the condensed steam which leaves the engine, has been determined. The mechanical means employed for measurement are generally, tanks for the feed, and overflow weirs for the discharge water. On referring to the author's last trials, it would be seen that the observed amounts of heat rejected per pound of feed-water were 1176·5, 969, 1037, 1120. The first value may be slightly high, for although both injection cocks were opened at 3.52 p.m., the one which supplied the circulating pump was accidentally closed again until 4.10 p.m., while that for the feed was full open all the time. The error cannot be a serious one, because it takes only fifteen double strokes of the circulating pump to fill all the water spaces of the condenser. The engine having accidentally been stopped between Nos. 15 and 16, it is reasonable to assume that water had accumulated in the cylinders, which accounts for the low results in Nos. 16 and 17, and perhaps even No. 18; the latter was measured about twenty minutes after restarting. Water meters have unquestionably been brought to a high state of perfection, but none give correct readings if air should get mixed with the water, as is sure to be the case in a marine engine, unless the feed-pump is worked automatically, and unless the circulating pump is driven by a separate engine. In the author's experiments, however, the trouble to be expected with a meter, if used for measuring the flow of brine, was not that air would get into it, but that its frictional resistance would produce an irregularity in the supply. In fact, the only practical plan of using a meter would be to couple it to the engine, and thus drive the brine into the feed or circulating water, making the necessary allowances for leakages.

Chemical determinations: (1) *Salt tests.*—In the experiments the nitrate of silver test for salt was used. A large stock solution was prepared of nitrate of silver and distilled water—about 120 grains to the gallon—from which the accurately graduated burette was replenished. The sample of water to be tested was poured into the beaker, to which a few drops of a strong solution of yellow chromate of potash had been added. All the sea-water samples were first diluted down to the strength of the salted feed-water. A reading was now taken of the upper level of the nitrate of silver solution, of which as much was then run into the beaker as would just cause the sample to change its colour from a pale yellow to a reddish brown. With a little practice this could be done with the greatest nicety, as is shown by the readings of the salinity of Glasgow town water, in which there were only 1·3 grains of salt per gallon. The change of colour could not be read with the same precision when there were larger percentages of salt, because of a heavy milky precipitate of silver chloride. For fairly accurate and rapid determinations this test cannot easily be surpassed, but in inexperienced hands there is always a danger of obtaining too high a reading, because the change of colour must have taken place before it is noticed. To minimise this danger the sea-water samples were diluted down to the strengths of the feed-waters with which they had to be compared.

M. Volhardt's method: A more accurate test for salt is the following:—Prepare a weak aqueous solution of nitrate of silver and nitric acid, also a weak solution of sulphocyanate of ammonia; the two fluids should be of equal strengths. A preliminary determination of the salinity of a small portion of the sample is made as described, then a carefully measured volume of the sample is mixed with a carefully measured volume of nitrate of silver solution, but slightly more than required, so as to precipitate all the chlorides. This sample is put aside for a day in a dark place, and the clear fluid is drawn off and tested with the help of the above standard solutions. A drop or two of ferric alum salt index is first added, and then the sulphocyanate is nitrated into it out of the burette until a change of colour takes place. If this is too marked, a little nitrate of silver solution is added, and this zigzag titration continued until the neutral point has been reached. The differences of the readings of the two burettes are then subtracted from the volume of nitrate originally added to the sample, and the remainder is the exact volume of the weak nitrate of silver which was required to neutralise the salt in the sample. Both the above named tests ought to be carried out by artificial light. The clearing is net necessary with weak salt waters.

(2) *Alkali test.*—Many substances are known which change colour if transferred from an acid bath into an alkali one; but for the determination of the alkalinity of sea-water nothing is likely to surpass aurine as an index, if used as recommended by Mr. Tornö. Weak solutions of hydrochloric acid and water, and of caustic soda and water, are prepared, the two being made exactly equal in strength. They are poured into two burettes. A carefully measured volume of the water sample to be tested is poured into a Berlin bowl, a few drops of aurine dissolved in water are added, and the whole is then boiled over a Bunsen burner. The colour of the fluid will at once change from an imperceptible pale amber to a beautiful rose pink; measured quantities of hydrochloric acid are from time to time added from the burette until the rose colour has permanently disappeared, which is a sign that the hydrochloric acid is in excess. Boiling is necessary in order that all the carbonic acid in the sea-water, both free and combined, may be driven out. Drop by drop alkali solution is now added until the pink colour returns, then acid is added until it just disappears. The difference of the loss of solution from the two burettes is a measure of the alkalinity of the sample. A second sample from the same bottle is now measured out, and a slight excess—about 1 per cent.—of acid solution added, the boiling is proceeded with for about fifteen minutes, and then the neutralisation is effected as before. The strengths of the acid and alkali solutions were those adopted by the late Professor W. Dittmar, viz., each cubic centimetre contained as much caustic soda as would exactly neutralise one milligram of carbonic acid. These are the units adopted in the tables. Experiments which were subsequently carried out by me, with solutions having only one-tenth of the above strength, proved that a change of colour of the aurine index was quite perceptible on adding only ·01 cubic centimetre of the standard fluid, a quantity which affected the levels in the burettes by less than $\frac{1}{100}$in. However, having commenced the chemical determinations before I was fully aware of this extraordinary accuracy, I did not venture to dilute the fluids, and all

---

* Read at the Thirty-seventh Session of the Institution of Naval Architects, March 26th, 1896, slightly condensed.

the readings are made with the normal strengths. A still more accurate determination than any to be found in this paper could have been made if, instead of salt or soda, the rather expensive chemical, nitrate of soda, had been injected into the waters. The accuracy attainable with this substance is such that the capacity of one of the Tilbury graving docks, holding about 60,000 tons of water, could be determined chemically to within 1 per cent. of its true amount, if only 1 cwt. of nitrate were to be dissolved in the water, of which a few ounces would suffice for the analysis, which is a colourimetric one. The experiment would cost about £20. A notice will be found that the thermal capacity of sea-water is 0·973. No direct experiments on the subject seem to have been made, but the author discovered some by Mr. Schüller—Poggend. Ann., vol. cxxxvi.—on the specific heats of salt solutions, from which the above value has been estimated. The specific heat of chloride of soda is 0·21401, and the density of sea-water has been assumed to be 1·026.

Conclusions.—Having demonstrated the accuracy of this chemical method of estimating water quantities, it only remains to point out the advantages which can be obtained by its use. (1) The circulating water of a marine engine can be measured at sea; this has not been done before. The quantity of carbonate of soda—washing soda—required is approximately 2 cwt. per 1000 indicated horse-power per hour, which should be dissolved in a tank of fresh water holding about 60 gallons. (2) The feed-water of marine engines—300 c.c. samples should be collected—not fitted with slow working automatic pumps, can be measured either by injecting carbonate of soda brine or sea water. On account of the air which is mixed with the feed-water when the pumps are worked by the main engines, mechanical feed meters would not give accurate results under such conditions. (3) The method can be applied to the accurate measurement of the volume of water in small streams, and would be of special value in a mountainous district. It being possible to determine the salinity of water, holding only one grain per gallon in solution, to within 1 per cent. of its true amount, it would be necessary to add salt brine—containing 50 oz. to the gallon—at the rate of only one gallon per minute to a stream which delivers 350 gallons of water per second, and to collect a sample after thorough mixing has taken place. The measurement of the volume of water supplied to towns for drinking purposes is frequently done by weir gaugings, which are said to be unreliable to the extent of 5 per cent. In conclusion the author begged to thank Messrs. R. Napier and Sons, Messrs. Ross and Duncan, Messrs. Muir and Houston, Mr. C. M. Aikman, Mr. R. J. Beveridge, Mr. Sinclair Couper, Mr. D. Johnson, and Mr. J. Thom for their assistance during these experiments, which have now extended over a period of two years, and have entailed an amount of labour which is only faintly indicated by the five trials that have been submitted in this paper.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Tramways.—The mileage of tramways in the United States averages about 15,000 miles, owned by nearly 1000 companies, with a capital stock aggregating £150,000,000, or 10,000 dols. per mile. Of this total mileage about 75 per cent. is operated by electricity, 14 per cent. by horses, 5 per cent. by cable, and 6 per cent. by miscellaneous systems. In all the large cities there is a great network of city and suburban lines, the former extending into the densest parts of the cities—sometimes with single tracks in narrow streets, the cars going in one direction along one street and in the opposite direction in the next street—and the latter extending to the farthest suburban settlements. The following table gives an idea of the great extent of tramway mileage in some of the principal cities:—

	Miles.
Louisville	150
Philadelphia	400
New York (including 100 miles of elevated railway)	427
Boston (including suburban lines)	550
Brooklyn (including 55 miles of elevated railway)	405
Chicago (including 66 miles of elevated railway)	659
St. Louis	291
Baltimore	225
Washington	140
San Francisco	231
Pittsburgh	242
Cincinnati	261
Cleveland	192
Detroit	166

Railway operating statistics, Chicago, St. Paul, Minneapolis, and Omaha Railway.—The following is a summary of the operating statistics of this road for the year 1895:—

Passenger trains, number	23,804
Passenger trains, mileage	1,776,140
Number of cars per train, average	5·03
Passengers per train-mile	39·09
Journey per passenger, miles	44·95
Earnings per train-mile, dollars	1·19
Rate per passenger per mile, cents	2·479
Receipts per passenger, dollars	1·114
Total number of passengers	1,544,387
Freight trains, number	48,290
Freight trains, mileage	2,972,741
Number of cars per train, average	19·16
Number of miles run per train	61·56
Distance hauled per ton, miles	148·24
Earnings per train-mile, dollars	1·80
Rate per ton per mile, cents	1·150
Receipts per ton, dollars	1·705
Total tons of freight	3,141,062
Length of railway, miles	1492·23
Gross earnings per mile, dollars	5031·91
Operating expenses per mile, dollars	3241·23
Net earnings per mile, dollars	1790·68
Total mileage of engines	6,398,149
Repairs of engines and tenders per mile, cents	4·44
Enginemen, firemen, and wipers per mile, cents	7·05
Oil, waste, and tallow per mile, cents	0·24
Fuel, per mile, cents	10·30
Total cost per engine-mile run, cents	22·03
Miles run per ton of coal	25·46
Miles run per pint of oil	18·20
Miles run per pound of waste	134·38
Earnings per train-mile, dollars	1·58
Expenses per train-mile, dollars	1·02
Net earnings per train-mile, dollars	0·56
Passenger car mileage	9,821,868
Freight car mileage	56,077,449
Coal consumed by locomotives	246,887
Coal, cost per ton, dollars	2·57
Earnings—	
Passenger, per cent.	22·92
Freight, per cent.	71·31
Express, per cent.	2·10
Mail, per cent.	2·73
Miscellaneous, per cent.	·94
Total	100·00
Operating expenses—	
Maintenance of way and structures, per cent.	19·31
Maintenance of equipment, per cent.	17·79
Conducting transportation, per cent.	47·54
General expenses, per cent.	9·02
Taxes, per cent.	6·34
Total	100·00
Operating expenses, per cent. of gross earnings	60·33

Pumping station.—The new Queen-lane pumping station for the water supply of Philadelphia is within the limits of Fairmont Park, and had to be made of architecturally pleasing design, in order to meet the requirements of the Park Commission. It is in the Italian renaissance style, and has an engine-house for four great pumping engines, a boiler-house for twenty-four boilers, and an intermediate building containing the engineer's office, electrical room, dressing room, and offices for the Park Commission. The engine-house is 136ft. long by 81ft. wide, one storey high, with a height of 48ft. from floor to roof-plates. The basement is 21ft. in the clear. The walls are faced internally and externally with buff bricks, the inside being glazed for a space of 6ft. from the floor. The boiler-house is 180ft. long by 81ft. wide, and is also in one storey, brick-faced, similarly to the engine-house, with a height of 36ft. from floor to roof-plates. It has a basement 17ft. by 75ft. in each end, that in the south end being used as a machine shop, while that in the north end contains two hydraulic lifts, and opens into the mouth of the tunnel to the coal shed. The south basement has a clear space of 10ft., the north of 12ft. The intermediate building is two stories high; the first 16ft. in the clear, the second 10ft. The external walls of the buildings are enriched with belt courses, arch mouldings and foliated terra-cotta frieze. A large granite tablet, 15ft. long by 8ft. high, set in terra-cotta ornamentation, occupies the centre space over the door in the front wall. The cut stone used in the buildings is Indiana limestone. The floor of the boiler house and of all the basements is composed of cement concrete, with a granolithic finish. There is in the engine house, at a height of 42ft. from the floor, an electric travelling crane, with a clear span of 75ft. It has a lifting capacity of 20 tons, and has assisted materially in facilitating the work of erecting the engines. The lifting tackle can be placed over any point in the engine-room, except a narrow space around the walls. The chimney or stack is built central to the front wall of the boiler house, but separated from it by a space of 9ft. The inside diameter of the barrel is 12ft., and it rises to a height of 201ft. above the ground in front of the building. The external wall of the stack is built in the form of a tower, with a base 27ft. square. At a height of 181ft., where the tower ends, it is 24ft. on a side. The foundation of the stack is about 24ft. below grade level, the bottom course being 37ft. square and 2ft. thick, the stepping courses averaging 18in. in thickness. There is a cut stone base 6ft. in height from grade level. All the superstructure is of hard stretcher bricks, faced with buff bricks. The top of the tower portion of the chimney, for a height of 38ft., is decorated with terra-cotta moulded brick pilasters, with foliated caps, and an ornamental balustrade. On the four sides of the chimney below the main cornice there are ornamental terra-cotta panels, 11ft. by 14ft. Wire-glass is used in the boiler-house ventilators, but as it was found to crack—though it did not leak or give way—it is not used in the lights of the ventilators on the engine-house roof.

Water-works pumping engines.—The Queen-lane pumping station of the Philadelphia water-works has four vertical triple-expansion engines, with single-acting plungers, each engine having a capacity of 20,000,000 gallons in twenty-four hours. They work under an initial steam pressure of 140 lb., and pump through a rising main of 48in. diameter, about 8000ft. long, into a reservoir at a height which will give a static head of about 250ft., equal to a pressure, allowing for friction, of about 110 lb. The cylinders are 37in., 62in., and 96in. diameter. There are three single-acting plungers, each 34½in. diameter, all of 54in. stroke. The steam inlet to each high-pressure cylinder is 8in. diameter, and the suction and discharge pipes are each 40in. diameter at the pump, enlarging to 48in. a few feet away. There is a 48in. check valve placed in each discharge pipe, and the suction pipes are provided with foot valves. The length of suction pipes is about 300ft. The height of suction lift at ordinary stage of water in the river is about 17ft. Each pump chamber contains ninety suction and ninety discharge valves, with a net area of nine square inches through each valve. The area of the plunger is 934 square inches, and the area through the valves 810 square inches. When the pump is running 22½ revolutions per minute, which is the required speed to deliver 20,000,000 gallons of water in twenty-four hours, with an allowance of about 3 per cent. for slip, the speed of the water through the valves is 3·6ft. per second. The admission of steam to the high-pressure cylinder is controlled automatically by a Porter governor. The steam gear is of special design to give the best steam distribution and highest economy, and is particularly simple and accessible for adjustments. The steam valves are of the gridiron slide pattern, and are actuated by cams, which give quick opening and closing movements. These valves are placed at an angle so as to insure their seating, and they are held against the seats by the pressure of the steam. Being of the gridiron type, they have very small movements; and being located in the heads, give the minimum clearance, not exceeding in any case 2½ per cent. of the piston displacement. All the cylinders are jacketed with steam, and there are re-heaters between the cylinders. The jackets and re-heaters, with the exception of the low-pressure jacket, use steam of boiler pressure, the low-pressure jacket steam being reduced to 50 lb. by means of a reducing valve. All drain and jacket steam is trapped, and returned automatically to the boilers. Each pump has two fly-wheels 18ft. diameter, and weighing 40,000 lb. The air pump is single-acting, 28in. by 36in., and is driven by a beam from the low-pressure plunger crosshead. The total weight of the engines, piping, and steel substructure is 2500 tons. The greatest height from the foundation is 56ft., and the space occupied by each pump is 46ft. by 18ft. The guaranteed duty is 110,000,000 foot-pounds, during a run of thirty days by the regular city employés, and using a fair quality of coal.

Garbage disposal.—Tenders were received recently for disposing of the garbage of New York City as follows:—H. L. Fox, 2s. per ton—2000 lb.—using the Vivartas furnace cremation process, with a furnace at each of the twenty garbage dumps on the river front; Z. F. Magill, 5s. 8d. per ton, using the Brown cremation process, with one large central plant; Kelly and McGelhan, 6s. 2d. per ton, using a new cremating process with an inclined rotating cylinder; Merz Extractor Company, 3s. 9d. per ton, using the Merz utilisation process; and R. W. Peterson, 6s. per ton, using the Arnold utilisation process. All the bidders but Fox and Magill proposed to carry the garbage away in scows, as at present, to a plant outside the city. All the processes mentioned are already in actual service in other cities with the exception of the Kelly and McGelhan furnace. The city estimated that there would be 800 tons of garbage per day to be disposed of, but some of the bidders considered this to be too high. All the tenders were rejected, as on a former occasion, and it is expected that new specifications will be issued and new bids asked for on the basis of a lump sum per year, regardless of the quantity of garbage, instead of a price per ton, as the number of tons is an uncertain quantity, and if the quantity fell much below the estimate it would not pay a contractor to put in an expensive permanent plant. At San Francisco, a contract for operating a garbage crematory for fifty years has been given to M. L. V. Merle for £1000, although two other bidders tendered £430 and £213 in cash, and from 2 per cent. to 5 per cent. of the gross receipts. The contractor will put up a cremating furnace with a capacity of 250 tons per day.

The first-class battleship Majestic, flagship of the Channel Squadron, is to undergo a long series of trials. The programme, as arranged by the Admiralty, includes runs over the measured mile in Stoke's Bay as follows:—Two runs at 60 revolutions with a corresponding speed of 10 knots; four runs at 75 revolutions—12½ knots; four runs at 85 revolutions—14 knots; four runs at an indicated horse-power of 10,000 with a corresponding speed of 16½ knots; and two runs at the slowest possible speed consistent with having the vessel under proper control. The second series will be point-to-point trials between Start Point and the Lizard. This provides for the vessel steaming at 12,000 indicated horse-power—forced draught—for 4½ hours, heading westward for one-half the time, and in the opposite direction the other half. Before the trials are commenced the vessel is to be brought to a draught of 27ft. forward and 28ft. aft.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The April quarterly meeting of the Midland iron trade was held in Birmingham to-day—Thursday—and it may be considered a satisfactory gathering. Confidence was expressed that although the trade improvement is not very marked at present, yet that the improvement would become more emphasised as the year proceeded. Some well-known authorities prophesied two or three years of prosperity, and pointed to the progress of shipbuilding, and to the following by foreign Governments of the liberal policy adopted by England; also to the extension of railways in various parts of the world, more particularly in Africa and in the East. The light railway movement at home was another feature which such critics regard with hopefulness.

All branches of the engineering trades of the city and district were reported to be well occupied, and to have had a good quarter.

Marked bars were re-declared at £7 as the basis price, with 12s. 6d. extra for the L.W.R O. brand of the Earl of Dudley. Demand is improving. Merchant bars are quoted £6 to £6 5s., and common £5 5s. to £5 10s. Black sheets were obtainable at £6 12s. 6d. to £6 15s. for doubles, and £8 for lattens. In this department the great production has caused a weakening of prices, and doubles are easier to buy than in January by about 10s. per ton. Compared, however, with this time a year ago, current prices are an improvement of about 10s. on doubles and £1 on lattens. Galvanised corrugated sheets in Liverpool are £10 2s. 6d. to £10 5s. for 24 gauge, compared with £10 7s. 6d. to £10 10s. in January, or a drop of about 5s. on the quarter. But a year ago they were quoted £9 10s. f.o.b. Liverpool, so that progress has been made during the twelve months to the extent of 17s. 6d. Stamping sheets this afternoon were quoted £9 10s., and best thin sheets £11. For hoops and thin strip, £6 7s. 6d. was asked; for nail rods, £6 10s.; and for tube strip, £5 10s.

With reference to steel, the Scotch and North of England firms are so busy upon shipbuilding orders that they have been lately allowing orders for other descriptions of work—including mainly engineering sorts—to pass them—a circumstance which on several occasions has proved advantageous to this district. Prices are steady at £4 10s. for Bessemer blooms and billets, £5 12s. 6d. to £5 17s. 6d. for angles and boiler plates, £7 5s. to £7 10s. for sheets, and £5 15s. to £6 for bars. Basic steel girders and angles are £5 10s., and boiler plates £6 5s. Activity has characterised the whole of the quarter in steel, and makers are still well placed. Of structural steel generally it may be said that it is 10s. a ton better than this time last year. An excellent business was done this afternoon.

Staffordshire cinder pigs were quoted this afternoon 36s.; part-mines, 42s. 6d.; all-mine hot blast, 55s. to 57s. 6d.; and cold blast, 90s. These values are about the same as in January. The production has been heavy throughout the quarter. Values, however, are somewhat better than a year ago, the quotation for Staffordshire all-mine hot blast being then 52s. 6d. to 55s.; part-mines, 38s.; and cinder sorts, 36s. to 37s. A good deal of business was done this afternoon in Northamptons, Derbyshires, and Lincolns. Derbyshires were quoted 42s. to 43s.; Northampton forge, 41s. to 42s. 6d.; and Lincolns, 44s. to 45s. These figures are about the same as in January; but they show a considerable advance upon this time a year ago, when Lincolns were only 39s. to 40s. at stations, net. Derbyshires, 38s. to 38s. 6d., less 2½ per cent. delivered to works in this district, and Northamptons 37s. 6d. upwards.

Touching the probable future of the mechanical carriage trade, interesting reference was made at the recent annual meeting in Birmingham of Forder and Company, the hansom cab manufacturers. Mr. Hipwell thought that by the exercise of a little ingenuity on the part of the directors, some novelty might be brought out. He did not know whether the horseless conveyance would be likely to make headway in England, but it was possible it might, and he did not see why the company should not be the first in the field with mechanical cabs. The chairman—Mr. C. Forder—said he and his brother were the founders of the company. When they went out the turnover was up to £36,000 a year, but when they returned it had gone down to £17,000. They were gradually getting the trade back, and when the turnover reached £25,000 a year they would be able to pay a dividend of 10 per cent. As to the new motor, that was engineers' work at present, and not a carriage-builder's. They held all the best patents for hansom cabs, and watched every new invention very narrowly. When the new motor was perfected they would be able to supply the carriages, but it would be out of the company's line to undertake the engineering part of the work.

S. A. Daniell, Limited, is the title of a company which has been registered with a capital of £10,000 to carry on the business now conducted by Howard S. Pearson, at the Lion Works, Edward-street, Parade, and St. Peter's-place, Birmingham, as the executor of Samuel A. Daniell, deceased, as manufacturers of engineers' and other tools, copying presses, &c., iron and brass founders, and mechanical engineers. The first director is Mr. Fred Hadley, manufacturer, King's Heath, the qualification being £300, and the remuneration £200 per annum.

The Tipton Mines drainage engineering scheme was stated at the last meeting held of the South Staffordshire Mines Drainage Commissioners, to be proceeding as rapidly as possible; but it was pointed out that until the whole of the agreements with the various authorities and private owners had been signed, sealed, and delivered, no plant could be laid down.

An instructive speech upon light railways was made by Sir Alfred Hickman, M.P., at Wolverhampton a day or two ago at the annual meeting of the Locomotive Steam-enginemen and Firemen's Friendly Society. He trusted various existing restrictions would be removed by the Light Railways Bill. With regard to the cost of a light railway, he might say that a firm had offered to make a line for about £3000 a mile, and equip it with carriages and rolling stock, whereas he understood that some lines had cost from £15,000 to £16,000. Light railways, he contended, would be beneficial for farmers and other members of the community, and they would give an impetus to railway enterprise.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The holidays during the past week have tended for the time being to still further slacken off buying, and there has been a general absence of animation throughout the market. In some quarters the immediate outlook is scarcely regarded with so much satisfaction as recently, and there would certainly seem to be a quieter tone in this district as compared with other important centres of the iron trade. Generally, however, the position continues strong as regards prices, makers showing no disposition whatever to give way in the least, whilst in the steel trade the tendency is decidedly in an upward direction, the large Government inquiries now coming forward necessarily helping up this section of the market. The lull just now being experienced as regards new buying is for the most part looked upon as not more than temporary, and the only effect is perhaps to force second-hand iron upon the market, here and there, at lower figures, where merchants or dealers are not in a position to hold on.

There was only a small attendance on Tuesday's Manchester iron market, with little or no inquiry of any weight stirring. Pig iron was in but slow request, owing, in some measure, to the holidays, but chiefly to the fact that both merchants and users are well covered in most cases, so far as present requirements are concerned. Prices, however, generally maintain a firm tone, although in some cases odd parcels in second-hands might be bought for immediate delivery at under market rates. Makers hold strongly to late quotations, and for local brands are getting their full list rates of 46s. 6d., less 2½, for foundry qualities, whilst in district brands it was decided, at a meeting of Lincolnshire makers, to maintain the minimum quotations at 42s. for forge to 44s. for foundry, net cash, delivered Manchester, a trifle over these figures being got in some cases, and Derbyshire foundry remains at 46s. 6d. to 47s. net cash, delivered Manchester. With regard to outside brands offering in this market, makers are asking rather higher prices, and are not taking anything under 47s. 1d. net cash for No. 3 foundry, Middlesbrough, delivered Manchester, whilst merchants scarcely go more than 3d. below this figure, but for delivery Dock Quays 45s. 6d. would still be taken in some cases; Eglinton, delivered Lancashire ports, is now generally quoted about 47s. 6d., and for delivery Dock Quays, Manchester, 49s. 9d. to 50s. net prompt cash.

A fair amount of new business is being secured by manufactured iron makers, and forges are kept fully engaged, with a firm tone as regards prices. Lancashire bars, delivered Manchester district, are steady at about £5 10s. to £5 12s. 6d., and North Staffordshire qualities £5 12s. 6d. to £5 15s.; whilst sheets remain at about £7 10s. to £7 12s. 6d., and hoops at the Association list rates of £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, with 2s. 6d. less for shipment.

In the steel trade a strong tone is reported generally, with a steady upward movement in hematites, good foundry qualities not now being quoted by makers under 58s. and 58s. 6d., less 2½, and ordinary steel billets range from £4 10s. up to £4 15s. net cash, with boiler plates averaging £6 7s. 6d. to £6 10s. per ton, delivered in the Manchester district.

No material change is noticeable in the metal market; business in all descriptions is satisfactory, with an active demand generally. There has been no further advance in the official list rates for manufactured goods; but, as I have previously noted, makers are getting ½d. per lb. above their quoted rates, on small orders for brazed brass and copper tubes.

The position in the engineering trades is one of continued increasing activity, and evidence of this is afforded in the out-of-work returns of the trades union societies, which show a steady decrease in the unemployed list for this immediate district. The Steam Engine Makers' Society has now only 1 per cent. of the total membership of the society on donation benefit, which is less than one-quarter of the number reported on the unemployed list for the corresponding period of last year, and the tendency is in the direction of a still further reduction. The reports received by the above society from the different districts as to the condition of trade are again of a most satisfactory character, practically all departments being in a good position as regards work in hand, and it is very exceptional where establishments are not fully employed, with new orders coming forward freely, especially amongst heavy stationary engine builders. Marine centres also show a continued steady improvement, although in one or two isolated cases the position is still not very satisfactory.

Messrs. B. and S. Massey, of Openshaw, have just completed a large foreign order, which includes, among numerous other hammers, six of the Rigby type, with framing composed entirely of riveted steel plates and angles. This arrangement secures special advantages even in small sizes of hammers, and much more so in large hammers, by reducing the cost of transport, and the risk of breakage through carelessness in transhipment. The hammers, which are of the 5 cwt. and 10 cwt. sizes, are fitted with Messrs. Massey's combined self-acting and hand-worked valve gear, and have an exceptionally large "overhang" or space from the anvil pallette backwards to the upright part of the standard, so that the greatest possible working space is afforded for operating the hammer. Messrs. Massey have also just completed two unusually large and powerful steam stamps of the pillar form, with a falling weight of 15 cwt. for stamping parts of guns, the tup sliding between round iron pillars, which are hollow tubes, and strong stout bolts passing from the bottom of the base-block to the nuts at the top of the stamp for binding the whole firmly together. These stamps, of which an illustration with more complete details, will shortly be given in THE ENGINEER, are double-acting, the steam being employed not only for lifting, but also for accelerating the fall of the tup.

In the coal trade the position shows no signs of any improvement, at any rate in the immediate future. Only the slowest possible demand comes forward for all descriptions of round coal, and both in the better qualities and the inferior descriptions, even with the present limited output, supplies continue in excess of requirements, with an easing tendency in prices. The demand for house-fire qualities is necessarily largely affected by the mildness of the season, and many of the collieries closed the winter with heavy stocks on hand. Nominally there is no quotable change in list rates, but these are only being got on small orders, very low figures having to be taken for anything like quantities. The low class of round coals used for steam, forge, and general manufacturing requirements, continue a drug upon the market, and in the keen competition to secure orders prices are forced down to an excessively low point.

At the pit-mouth, best Wigan Arley coals do not average more than 9s. 6d. to 10s. per ton; Pemberton four-feet and second qualities of Arley, 8s. to 8s. 6d.; common house-fire coals, 7s. to 7s. 6d.; with about 5s. 3d. up to 6s. 3d., according to quality, representing the full average prices that are obtainable for ordinary steam and forge coals at the pit-mouth. Engine fuel is becoming rather scarce, if anything, owing partly to the limited demand upon round coals, and partly to the increased requirements for slack for coke-making purposes, owing to the general activity in the iron trade. Prices necessarily show a hardening tendency, and although it is exceptional where any really appreciable advance is being got, ordinary slack could scarcely be bought under 3s. 6d., with better qualities, 4s. 6d. to 4s. 9d.; and some special sorts, 5s. at the pit.

The shipping trade remains depressed, with common round coals, for bunker purposes, not fetching more than 6s. 9d. to 7s. 3d., and better sorts 7s. 6d. to 7s. 9d. delivered at the Garston Docks or High Level, Liverpool.

Barrow.—The week's business in hematite pig iron has been on a comparatively large scale, and the Easter holidays do not seem as usual to have checked the influx of orders. Bessemer qualities are in especial request, and orders are well held. 39 furnaces remain in blast, as compared with 28 in the corresponding week of last year. Stocks have been reduced during the week to the extent of 2090 tons, and now stand at 300,939 tons. Prices show an upward tendency. Warrant iron is quoted at 47s. 8½d. net cash sellers, 47s. 8d. buyers. Makers are still quoting 50s. per ton net f.o.b. for mixed Bessemer numbers.

Iron ore mines are more busily employed, and the trade in native qualities shows a distinct improvement. Ordinary sorts are at 10s. per ton net at mines. Spanish is still largely used, and is quoted at 12s. 9d. at West Coast ports.

Practically every branch of the steel trade is busy. Orders are plentiful for rails, ship and boiler plates, hoops, billets, and merchant steel generally, and there are indications, what with the orders on hand and those offering, that a very brisk continuance of trade will be experienced throughout the year.

There is nothing new to report in the shipbuilding and marine engineering branches of trade.

Coal and coke find good markets, and prices are firm, but not quotably higher.

Shipping is more active. The exports of pig iron during last week represented, from West Coast ports, 5650 tons, and of steel 7670 tons, as compared with 4156 tons and 5120 tons respectively in the corresponding week of last year, an increase of 1494 tons of pig iron and 2550 tons of steel. The aggregate shipments to date this year show 84,168 tons of pig iron and 113,313 tons of steel, as compared with 67,310 tons of pig iron and 98,587 tons of steel in the corresponding period of last year, an increase of 16,858 tons of pig iron and 14,726 tons of steel.

There is every prospect of a big scheme being started at Barrow for the development of the great salt deposit on Walney Island. It is proposed to build works on the south end of the island, and to ship manufactured salt from a pier already in existence alongside the site of operations. Other works for the manufacture of alkali and other chemicals are contemplated. The new works are likely to be of very great advantage to the trade and commerce of Barrow.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

VERY little work has been done of late, owing to the Easter holidays, which have been most freely enjoyed, the exceptionally beautiful weather and the slackness of trade alike contributing to that issue. Trade is now being resumed, and the general state of coal continues very much as previously reported. Both the house and steam coal pits are quiet, and considerable concessions have to be made to clear off stocks. The tonnage sent to the metropolis does not increase, and is not likely to do so now, as summer weather gets more assured. Another serious factor in keeping prices low is the keen competition of the seaborne fuel. Quotations, though unaltered on the lists, are exhibiting a downward tendency, and merchants stocks are not commanding above the low rates ruling last summer, while in the case of secondary qualities even lower values have to be accepted:—Best Silkstones, 8s. to 9s. 6d. per ton; ordinary ruling from 6s. 9d. per ton; Barnsley house from 7s. 6d. to 8s.; Flockton, 6s. 9d.; and thin seam, 6s. per ton.

The Eastern Counties are doing but a slight business. Steam coal is in fair request, and, though competition is very keen, the local collieries are forwarding an average tonnage to the Humber ports. Freights are very low at present. The majority of the business is being transacted by the larger collieries both with the Humber and the other ports. A fairly good weight is being called for by the railway companies on contract account, although the large supplies have the effect of making prices low. Barnsley hards command from 6s. 6d. to 7s. per ton; inferior sorts, 6s. per ton. Gas coal is in about the same moderate condition as steam sorts. Prices are scarcely maintained, the coal contracts recently entered into by Durham firms at the rate of 6s. 3d. per ton, having the effect of keeping values down. Manufacturing fuel is in good demand, supplies being abundant, though lower than was the case a few weeks ago. Quotations remain about the same. Small nuts, 4s. 6s. to 5s. 6d. per ton; screened slack, 3s. 6d. to 4s. 6d. per ton; pit slack, 2s. 6d. per ton, and smudge 1s. per ton. Coke is in a better condition, and Derbyshire, Northamptonshire, and Lincolnshire are taking a good supply for smelting purposes. Prices are firm at 8s. to 10s. per ton.

The heavy industries of the city continue satisfactory. Makers who booked a large number of orders in the early part of the year have now the pleasant prospect of being in a position to find full employment for their men for a considerable time to come. A few manufacturers are complaining of the absence of orders. The trouble in the Transvaal has had rather an adverse effect on one or two departments of the Sheffield trades. The demand for machines, bars, sheets, and similar goods are not coming in so freely as was the case before Dr. Jameson crossed the border. It is expected that matters will settle down peacefully ere long, and the business done before the outbreak will be resumed with some large additions. It has not had the effect of stopping the large consignments of steel, tools, and general hardware goods now leaving Sheffield for the South African market. Many firms are doing quite as large a business with that part as they did before. The iron trade, as well as the steel, is in the same healthy condition. Values are well maintained. Hematites realise—West Coast, 55s. 6d. to 57s. 6d.; East Coast, 54s. 6d. to 55s. 6d. at makers' works; Lincolnshire pig iron, 41s. 6d.; foundry, 42s. 6d.; Derbyshire forge, 39s. 6d.; with foundry, 42s. 6d.; bar iron, £5 10s.; and sheets, £7 10s. Many of the local companies have issued their balance-sheets during the last week or two, and they show a healthy state of affairs all round. Good employment is reported in the rolling mills. At the carriage and wagon works in this district better business is coming in, and the men are more fully engaged than was the case a few weeks ago, while the wheel makers report large accessions of business.

In the lighter industries the end of the quarter is finishing very quietly for many houses. March is generally one of the quietest months the silver platers have during the whole year, and the present month has been no exception to the rule. The business at this season is nearly all concentrated on the requirements of hotel and boarding-house keepers at the summer resorts, as well as goods suitable for prizes, &c., at shows and sports, in which a very large business is now done. The request for forks and spoons is quite equal to what it was a week or two ago. The tendency of buyers to purchase the sterling silver goods in preference to plated wares or hollow ware goods still continues. In some of our larger establishments special attention is being paid to a pressing demand for old Sheffield patterns. The cutlery and tool makers report that they have as much business on hand as will keep their hands employed well into the autumn. The business with the Australasian Colonies has considerably advanced. There is a very large request for sheep shears from these markets as well as from New Zealand, and several houses have booked some very good orders in cutlery and similar hardware goods. A large quantity of electro-plate, in the cheaper kind, is being sent to these Colonies. The trade with India is not so good, the value of the rupee showing a distinct tendency to falling lower. The very mild weather at present being experienced has had the effect of causing an excellent request for field and garden tools, a business which has set in much earlier than is usual. In many cases makers cannot cope with the enormous requests of their customers. A good number of scythes and similar goods are being despatched to both the home and distant markets, and the prospects are exceedingly encouraging for the coming season.

The annual meetings of shareholders in local companies now being held do not exhibit any great improvement in the trading up to December 31st, 1895. The report in each case invariably sets forth that the revival set in during the latter half of the year, and that its effects will not be fully apparent until the current twelve months' trading is ascertained. The companies who make up their balance-sheets to March 31st or the middle of this year will afford a clearer idea of the volume and value of business done. At every meeting the prospects of 1896 are always accompanied with the significant proviso, "If the colliers keep the peace."

The reports from the Consular District of Sheffield to the United States during the quarter ended March 31st show a total value of £166,444, against £112,602 for the corresponding period in 1895 and £57,957 for the corresponding three months in 1894. Cutlery was sent to the States to the value of £29,819, and steel to the value of £84,444, the corresponding values having been £28,678 and £71,924 respectively.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

ON account of the holidays the market is quiet this week, but that was only what was looked for, and prices are fully maintained in all branches of the iron and allied industries. Pig iron makers especially are firm, as they have every reason to expect that, busy as they have been in March, they will be still busier in the current month, as the shipping season is now nearly in full swing. Thus the good prospects counteract any detrimental influence that might have resulted from the rather disappointing statistics issued by the Ironmasters' Association, an increase in stocks being reported where a decrease was generally expected, especially after the almost unprecedented exports.

The March shipments of pig iron were unprecedented, so far as the corresponding month in any previous year is concerned, for they reached from the Cleveland district no less than 102,908 tons, that being 33,646 tons more than in February, and 25,026 tons more than in March, 1895, and a March average is scarcely more than 80,000 tons. As compared with last year it is to be borne in mind that not only was the trade better this year, but the weather was very much better also, and permitted of shipments being made to ports which last year were icebound throughout the month. A large business was done with continental consumers and merchants last month, much more than is usual in March, and deliveries to Germany especially have never been heavier than they were last month, even in the busiest period of the year. This is due to the mild weather having allowed the inland waterways on the Continent to be open much earlier in the year than usual. Last month over 32,000 tons of pig iron were shipped directly and indirectly to Germany, that being one-third of all the pig iron shipped from the Tees, and three-fifths of the quantity sent over sea. A larger trade than the average was done with Belgium, France and Spain, but by far the greatest increase was to Germany, which had last month double the quantity usually sent in March. Altogether the tonnage of pig iron shipped from the Cleveland district last month, as compared with the periods named, has been as under:—

	Coastwise. Tons.	Foreign. Tons.	Total. Tons.
March, 1896	50,425	52,483	102,908
February, 1896 ..	44,400	24,864	69,264
March, 1895	42,696	35,188	77,884
March, 1894	46,560	40,197	86,757

Seldom, indeed, do the shipments of pig iron from the Cleveland district exceed a hundred thousand tons per month, and that this quantity should be exceeded so early in the year as March is specially worthy of attention.

The price quoted for prompt f.o.b. deliveries of No. 3 Cleveland pig iron this week has been steady at 38s. 6d.; this is both makers' and merchants' figure, and practically the makers are not now being undersold by the merchants and speculators; in fact most sellers think it is to their interest to hold off for better prices. There is no pressure among second-hands to sell, as it is the early part of the month, and as they have nearly the whole month in which to take out their iron, they are not so much concerned in finding customers as towards the end.

The difference between the prices of Scotch and Cleveland warrants is being reduced, as the latter have advanced more quickly than the former. A few weeks ago the difference between the prices for the two was 9s. 3d., and even more; to-day it is only 8s. 6d., but it should be only 4s. 6d. or 5s., which is what it costs to deliver Cleveland iron to the Scotch founders. The intrinsic worth of the two classes of iron does not justify anything like such a difference as now is reported. And such a difference is having the effect of causing a greatly increased consumption of Cleveland pig iron at the Scotch foundries, as the owners of the latter can get it at considerably lower rates than they have to pay for native iron. Never in the history of the trade, except once, has more Cleveland pig iron been sent to Scotland than in the last quarter. The average of the corresponding quarter during the last ten years has been about 85,000 tons, but this year the quantity has been 111,426 tons, of which 9519 tons went from Skinningrove. Only in 1894 was this quantity exceeded, 118,932 tons being then sent. Of the pig iron exported from the Cleveland district, nearly one half was despatched to Scotland last quarter. It will thus be seen that the Cleveland ironmasters could ill afford to lose the Scotch market.

The Cleveland ironmasters' March statistics did not come up to expectations, as an increase of 3701 tons was reported where a decrease of at least as much had been looked for, especially after such heavy shipments. The stocks of Cleveland pig iron have been increasing ever since the end of October last, and the total increase has been 88,285 tons. The total output of pig iron in the North of England in March was 274,950 tons, or 20,170 tons more than in February, but the daily output was no more. The production of pig iron during the quarter was the best on record, and if continued at the same rate, it will for the year exceed 3,000,000 tons, the best hitherto reported being 2,963,000 tons in 1894. Altogether 798,925 tons of pig were made last quarter, of which 400,541 tons were Cleveland pig, and 398,394 tons hematite, basic, and spiegel. The Cleveland iron in the quarter exceeded the requirements by 49,886 tons. The following is the official record of the production and stocks of pig iron for the North of England:—

Make of Pig Iron.

Total	355,555	351,854	3,701	—

The quarter's exports of pig iron from the Cleveland district have been much above the average, affording good evidence of the improvement in trade. The average of the first quarter over the last ten years has been about 180,000 tons, but last quarter's was 241,912 tons, or 33 per cent. more. Never have there been larger oversea shipments, these reaching 100,723 tons, whereas the best previous was 87,316 tons in 1890. As compared with the first quarter of last year there was an increase of 67,249 tons.

The finished iron and steel industries are generally well employed, and prices are very firm. Manufacturers are well booked ahead, especially those producing rails and plates, and the settlement of the wages difficulty in the shipbuilding and engineering industries will give stability to the trade, particularly as the matter has been disposed of for a twelvemonth, and employers can enter into contracts with some amount of confidence, as they know what they will have to pay for labour, which forms such a heavy item in determining the cost of building and engining vessels. Manufacturers of plates ask £5 2s. 6d., less 2½ per cent. f.o.t., for steel ship plates, and £5, less 2½ per cent. f.o.t., has to be given for steel ship angles. Iron plates and angles do not seem to be in much demand, at least, the inquiry is much below what is reported for steel, and iron angles may be had as low as £4 15s., less 2½ per cent. f.o.t. Rails are in fair request, and work at the mills is plentiful. The export of railway material from the Tees is large to Western Australia, India, and Japan.

The wages question at the shipyards and engineering establishments in the North of England has been adjusted. The boilermakers have accepted the same terms as were granted to the Amalgamated Society of Engineers, viz., the men to receive an immediate advance of 1s. per week on time and 5 per cent. on piece prices, to be followed by a further 1s. advance on time wages in September, no further changes to be made until March next at the soonest. The shipbuilders have settled for 1s. 6d. per week on time wages and 5 per cent. on piece prices, to come into operation next month, and six months are to elapse before any further change can be made. The newly formed Conciliation Board in the ironmoulding business of the North-East Coast at its first meeting a few days ago had under consideration the application of the men for an immediate advance of 2s. per week on time wages, and 5 per cent. on piece prices.

It was settled that the men should receive an immediate advance of 1s. per week on time wages and 5 per cent. on piece prices, the question of a second advance being adjourned for a month. The brassworkers and the members of the National United Society of Engineers have settled on the same terms as the boilermakers. Only the enginemen and cranemen, the patternmakers, the drillers, and the strikers yet remain to be treated with, and it is not expected that any difficulty will be experienced.

The annual report for 1895 of the United Society of Boilermakers and Iron Shipbuilders, which has a membership of 40,000 and a history of sixty-one years, remarks that the demands on the employers for additional wages, which have been moderate in character, have generally been courteously conceded, and the disputes have been few and unimportant. The year was commenced with a balance of £157,546 17s. 5d., but the terrible weather in the first quarter completely stopped all shipyard work, and disastrously affected the boiler shops and bridge yards, and a large amount of money had to come out of the society's funds. The trouble on the Clyde and at Belfast was also a source of loss to the society, and the funds at the end of 1895 were £3500 10s. short of what was reported at the beginning. The total income of the society was £117,741 1s. 3d., and the expenditure £121,241 11s. 3d.

The steam coal trade of the North shows some improvement, and prospects are good, as the Baltic season is commencing; but as yet prices do not improve, and 7s. 9d. per ton f.o.b. is still accepted for best Northumberland steam coal. The exports of coal from North-Eastern ports last month were 1,343,284 tons, or 35,194 tons decrease on March, 1895. From Welsh ports 1,512,769 tons were shipped, decrease 150,453 tons. Coke is very firm, and there is not much on sale, but the little that is to be bought cannot be had under 13s. 6d. per ton delivered at Middlesbrough furnaces, while some sellers ask and realise 14s.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The Glasgow pig iron warrant market was closed from Thursday till Tuesday owing to the holidays, and this week there has only been a moderate business done. The market has been fairly steady, but operators do not appear to have sufficient inducement to turn over much iron at present. Transactions took place in Scotch warrants from 46s. 8½d. to 46s. 10½d. cash, and 46s. 11d. to 47s. 0½d. one month. There is very little doing in Cleveland warrants in our market, and the monthly report of the Cleveland stocks being less favourable than was expected, did not encourage investors in this iron. Cleveland warrants are quoted 38s. 3½d. to 38s. 4½d. cash, and 38s. 5½d. to 38s. 6½d. one month. There has been a moderate business in Cumberland hematite warrants from 48s. 5d. to 48s. 8d. cash, and 48s. 7½d. to 48s. 10d. one month. The state of the open market does not at present supply a very accurate idea of the condition of the pig iron trade, there being a very good legitimate business passing. Scotch-made hematite pigs are in active demand.

There are forty-three furnaces producing ordinary pig iron, thirty-five hematite, and three basic; the total of eighty-one, comparing with seventy-five at this time last year. Only a small quantity of pig iron was added to the stock in Glasgow warrant stores, partly due no doubt to the holidays; but apart from these, there has been less iron available for storing.

The prices of the special brands of Scotch makers' pig iron are steady, as follow:—Govan, Monkland, and Carnbroe, Nos. 1, 48s.; Nos. 3, 46s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 51s.; Nos. 3, 48s. 6d.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 49s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The pig iron shipments, as was to be expected, are smaller than usual, amounting to only 5913 tons, compared with 7931 in the corresponding week of last year. The larger proportion of the shipments continue to be sent coastwise, and the state of the export trade is very unsatisfactory. Indeed, were it not that the consumption at home is just now exceptionally good, the Scotch pig iron trade would be in a deplorable condition. Not only are the Americans taking hardly any iron from us, but merchants there are offering to ship iron to the Clyde, Liverpool, Barrow, and Workington at prices which appear to make it almost worth the attention of consumers on this side.

The market for finished iron has been quiet in consequence of the holidays, but makers and merchants are looking forward to an increased business as the season advances. In the home trade the likelihood is that this idea may be realised, and it is hoped too that some improvement may be experienced in the foreign branch of the trade, which has long been in an unsatisfactory state.

At the steel works there was as short an interruption for the holidays as could well be. Some of the workers were inclined to be attracted to local races, and in a number of instances it is found that the men are less anxious about making full time than in times when work is slack. Upon the whole, however, the steel works this week have been well manned, and are turning out large quantities of material. The demand for shipbuilding steel is greater, perhaps, at present than at any former time, and the contracts being placed would appear to indicate that this branch will be busy for a long time to come. Makers are not at all satisfied with the returns they are getting from this produce. Notwithstanding the increased quantities of steel that are being required, it is very difficult to obtain any increase in price. Merchants state that they are still able to place orders, when these are of any importance, rather below the prices that makers are quoting.

The shipping trade in coals has been moderately well employed, taking into account the interruptions caused by the holidays. Inquiries from the Baltic ports are now more encouraging, and the prospect altogether is not unsatisfactory, so far as the volume of business likely to be done is concerned. Prices are still very low. There is a rather better demand for superior qualities of household coals for shipment, but, on the other hand, the home demand for these is easing off to some extent. A large quantity of splint coal is being got rid of, but the market is slack, owing to full supplies. Coalmasters report that the demand for steam coals is particularly backward. The total coal shipments from Scottish ports during the week amounted to 162,738 tons, against 137,191 in the corresponding week of last year. Main coal is quoted, f.o.b. at Glasgow, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; and steam, 7s. 6d. per ton.

A conference of Scotch miners' delegates was held in Glasgow a few days ago to ascertain the result of the ballot recently ordered to be taken to show whether the men are willing to adopt a four days' working week. Representatives were in attendance from Fife, Kinross, Clackmannan, Mid, East, and West Lothians, Lanarkshire, Renfrewshire, and Ayrshire. The reports showed that a ballot had been taken only in Clackmannan and Lanark. This should not occasion any surprise to those acquainted with the state of the coal trade and the circumstances of the miners. The Lanarkshire ballot could not be of any weight, inasmuch as out of a total of 30,000 miners in that county, only about 3000 have any connection with the miners. The colliers seem for the time to have little confidence in the ability of their so-called leaders to afford them any substantial assistance, and wherever they can obtain free employment they are only too glad to take the full advantage.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

The usual Easter "upset," as matter-of-fact coalowners and shippers term the people's holiday, has passed, leaving the condition of trade practically unchanged, coal firm, with respect to its best class, iron and steel moderately good, tin-plate deplorably bad. One feature of the Easter week was the despatch from Newport, Mon., of a fine cargo of over 3000 tons of steel rails to Progresso. Another was the continuance of large cargoes of coal from Cardiff to Bombay, one of 5000 tons.

Up to, and including mid-week, the attendance on 'Change, Cardiff, was very small. On Tuesday there was quite a holiday character, and all the offices were closed at 10 a.m. A little degree of animation was becoming perceptible at the time of my dispatch, and possibly by Friday, something of the old vivacity will be exhibited. There is not much ahead that is disquieting. The Plymouth strike is relegated to the limbo of the strikes innumerable that have ended in comprises—which should have been initiated at the beginning—and the discharge note is evidently thrown over.

Cardiff coal prices, first, second and small, and also house coal quotations, remain unaltered; and it is not likely that any change, one way or the other, will be made before next week. Swansea Exchange quotations were published this week, though indicating little change. Best anthracite, 11s. to 11s. 6d.; second quality, 9s. to 10s.; ordinary large, 8s. to 8s. 9d.; small rubbly culm, 4s. to 4s. 6d., f.o.b. Swansea, cash thirty days, less 2½ per cent. Steam coals, best, 9s. to 10s.; seconds, 8s. 3d. to 9s.; bunkers, 7s. 9d. to 9s.; small, 4s. 3d. to 4s. 6d. Bituminous coals, No. 3 Rhondda, 9s. 6d. to 10s.; through, 8s. to 8s. 9d.; small, 6s. 3d. to 6s. 9d.; No. 2 Rhondda, 8s. 6d. to 9s. 6d.; through, 6s. 6d. to 6s. 9d.; small, 5s. to 5s. 3d. Other quotations were coke, furnace, 12s. to 12s. 6d.; foundry, 16s. to 17s. Patent fuel, 9s. 9d. to 10s. 3d. Pitwood, 10s. 9d. per ton into trucks.

The following quotations are the last issued at Swansea:—Pig iron, Glasgow, 46s. 9d.; Middlesbrough, No. 3, 38s. 4½d.; hematite, 45s. 10½d.; Welsh bars, £5 10s. to £5 12s. 6d.; sheet iron, £6 15s. to £6 17s. 6d.; steel, £6 10s. to £6 12s. 6d.; steel rails, heavy, £4 10s. to £4 12s. 6d.; light, £4 17s. 6d. to £5 7s. 6d. Bessemer steel, tin-plate bars, £3 17s. 6d.; Siemens, £3 18s. Steel rails in fair demand. Bar trade bad.

Tin plates, makers' quotations:—Bessemer steel coke, 9s. to 9s. 1½d.; Siemens, 9s. 1½d. to 9s. 3d.; ternes, per double box, 28 by 20 C., 16s. 6d.; best charcoal, 12s. 6d. to 12s. 9d.; wasters, 6d. to 1s. less; block tin, £60 7s. 6d. to £60 8s. 9d.

Cardiff report this week is to the effect that there was little or nothing doing in the house coal, coke, or patent fuel makes, and only a few inquiries for steam coal shipment after the holidays.

Pitwood remains at 14s. 9d. to 15s.; furnace coke, 13s. to 15s.; no higher figures having been maintained; foundry, 15s. 6d. to 19s. 6d., according to quality.

The tin-plate trade appears to be entering upon most trying times, the stoppage of Cwmfelin, Worcester, and other important works shows this in the most striking manner, and at a late meeting Sir John Jones Jenkins, who has always been looked up to as the man at the helm, expressed his intention of retiring practically from business. This step has been necessitated by his health, and though personally his loss from the councils of the plate manufacturers will be great, it is hoped that he will still be represented in the trade. His aim has been a steady and consistent one to introduce mutual goodwill and union amongst masters and men, but at no one time has he seen such a divided condition as at present, rates of reduction ranging from 10 per cent. to 25 per cent. Sir John told his hearers that they had driven the trade away not only to America, but to Germany and even to France and Spain. He looked upon tinning as having departed from them for a length of time. He could not say it had altogether departed, because a large quantity was used in this country, and he hoped they would keep that, and not open our own markets to foreign nations and lead the foreigner to send tin-plates into this country. The last rumour, and fairly authenticated, is the transfer of Gowerton steel works to Landore. One of the principals is stated to have confirmed this, and said that having melting furnaces at Landore, they would add mills, and carry on the manufacture of bars. In this case Gowerton will cease, at all events for the present, to work on the old lines.

In the Briton Ferry district the outlook is very gloomy. The Vernon Mills are stopped. At the Gwalia only two of the three mills have been at work of late, and the workmen at Baglan Bay are working upon a 10 per cent. reduction. Six mills are at work at the Villiers, and three at the Earlswood. At the Briton Ferry Works an average make of pig iron has been made, and the make at the steel works and at the Albion is satisfactory.

At Melincrythan, Neath, works are to start shortly by the Neath Steel Sheet and Galvanising Co.

The shipments of tin-plates from Swansea last week totalled 35,492 boxes; received from works, 39,864 boxes.

News from the United States reveals a condition of things little, if any better, than in Wales, and bands of Welsh platers are returning.

One item of good news I am glad to chronicle, and that is that a settlement has been effected at the Old Castle Works Llanelly. The management has agreed to accept a reduction of 15 per cent. on all piecework, and 10 per cent. on all day work; wages of labourers to remain.

A good deal of satisfaction has been expressed at Cardiff that the Bristolians have decided to forego the able and expensive projects of Mr. Wolfe Barry, and will be satisfied with the expenditure of only £93,000 in, as, a Cardiff authority states "tinkering the Avon." This leaves practically the Bristol Channel and the transatlantic trade at the direction of Cardiff. Swansea Harbour Bill has passed the third reading.

I am sorry to record a mishap to the Snowdonian Railway, and for a time, until the facts of the case have been brought before the public—by the aid, I should suggest, of a Governmen official —the people will fight shy of the introduction of Swiss railway methods into Wales. At present the question is whether the permanent way was to blame, or defects in the engine, or carriages, or brakes, or cogs. As one poor fellow who jumped off has since died, an inquest will be held. Travellers who constantly use the Festiniog line, which has been long in use without accident, are satisfied that the Snowdonian Railway is certain to come out all right in the end, and eventually be one of our great engineering successes. Mr. Aitchison, the general manager, is highly commended for his ability and presence of mind.

A new industry is foreshadowed for Swansea, the treatment of sulphwores from Australia by a new method, and the utilisation of the waste sulphates from local chemical works. It is yet early to mention the matter in detail, though it is stated that a large works has been selected for trial.

A case of record loading has just taken place at Roath Dock. The steamer Totosa, 5400 tons capacity, docked at Cardiff Tuesday week at 2 a.m., and began loading fuel at the Crown Wharf, finishing it Friday morning 3.45. Her actual working hours were only 57, during which 407,780 blocks of fuel were stowed.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

Changes of importance have not taken place on the continental iron market since last week, and there is consequently very little of interest to be related. On the whole, a further upward movement can be perceived in the different branches of the iron industry.

The accounts given of the iron trade in Silesia continue to be of a decidedly favourable character, almost all the makers and manufacturers having their order books well filled with contracts. Prices continue to improve, and are expected to rise still further when the liveliest season of the year has arrived. Pig iron is actively inquired for, and in a few instances up to M. 60 p.t. has been paid for forge pig. In the bar and girder trade the position of affairs is specially gratifying. The Silesian Rolling Mill Convention resolved to raise the prices for home demand and also for export to Russia M. 5 p.t.; for export to other countries prices remain the same as before.

Throughout the iron-producing districts of Austria-Hungary trade in raw and manufactured iron continues satisfactory. The various departments are pretty full of work. In railway material business is steadily improving. The hardware manufacturers, though better off for work than they were some months ago, still complain of being only partially well employed, and are looking forward to a more active demand in the new quarter. Official quotations are:—For common forge pig, 45 to 47 fl.; grey pig, 48 to 51 fl.; Bessemer, 48 to 51 fl.; ingots, 76 to 80 fl.; Styrian bars, 115 to 120 fl.; girders, 107 to 120 fl., according to quality; heavy plates for boilermaking purposes, 150 to 160 fl., in some cases 180 fl.; tank do., 130 to 135 fl.; steel plates, 140 to 160 fl. p.t.; tin sheets, 26 fl. per box; galvanised sheets, 205 to 260 fl. per ton.

The French iron market is very firm, and prices are well maintained. Forge pig, No. 2, is quoted 140f. p.t. in the North. In Paris merchant bars fetch 145f. to 150f. p.t., while for girders 155f. to 160f. p.t. is given. The engineering and building line is briskly occupied on the whole, and there is more work expected to be given out after Easter. French output in iron and steel was for 1895 as follows:—Forge pig, 1,516,168 t.; foundry pig, 489,721 t.; merchant bars, sectional iron, 654,645 t.; iron rails, 427 t.; iron plates, 88,599 t.; steel rails, 160,417 t.; ingots, blooms, &c., 362,527 t.; steel plates, 170,346 t. Output during the last three years was:—

	1895. Tons.	1894. Tons.	1893. Tons.
Forge pig	1,516,168 ..	1,600,113 ..	1,522,115
Foundry pig	489,721 ..	469,601 ..	480,981
Totals	2,005,889 ..	2,069,714 ..	2,003,096
Bars in iron	654,645 ..	685,319 ..	696,184
Iron rails	427 ..	684 ..	775
Iron plates	88,599 ..	99,778 ..	111,212
Totals	743,671 ..	785,781 ..	808,171
Bars in steel	386,168 ..	340,116 ..	323,023
Steel rails	160,317 ..	182,510 ..	207,358
Steel plates	170,346 ..	151,564 ..	133,651
Totals	716,831 ..	674,190 ..	664,032

In the Belgian iron industry a further increase in activity can be reported, all departments being likely to remain in healthy occupation for this quarter and the next. As to prices, there is an undeniable inclination to move upwards.

Satisfactory reports continue to come in from nearly all branches of the iron and steel trades in Rheinland-Westphalia. Only here and there establishments are still but moderately off for work; but this is mostly due to some special causes. The leading firms report a considerable quantity of new orders coming forward, which will secure employment for the remainder of the year. A strong demand prevails on the pig iron market, not only on home, but also on foreign account. Increasing firmness is also reported in the malleable iron business, bars and girders selling briskly; even hoops have been enjoying a better inquiry for some time past, and all round the lately advanced prices are well maintained. A slow but steady increase in demand is also noticeable in the plate department. The sheet mills continue to be vigorously engaged, and a further rise in quotations is likely to take place next week. Rivets, which for a long time remained neglected, have visibly improved of late, both as regards prices and demand. The machine and construction shops are very busy; the same may be told of the foundries, generally.

Output of pig iron in Germany, including Luxemburg, was, for February, 1896, 500,929 t., of which 135,687 t. were forge pig and spiegeleisen 35,276 t. Bessemer, 261,633 basic, and 68,333 foundry pig. Production in February, 1895, amounted to 434,704 t., that for January of present year having been 517,988 t.; from January 1st to 29th of February, 1896, 1,018,917 t. were produced, against 924,279 t. for the same period the year before.

Shipments of coke from the Rhenish-Westphalian district to the western iron-producing districts were:—

	To Luxemburg.	To Lorraine.	To Eastern France.	Totals.
1889	418,300 ..	442,250 ..	128,280 ..	988,830
1890	454,320 ..	549,860 ..	295,280 ..	1,299,470
1891	422,369 ..	624,367 ..	427,696 ..	1,474,432
1892	415,882 ..	473,508 ..	817,036 ..	1,706,426
1893	453,443 ..	420,496 ..	982,727 ..	1,856,666
1894	626,398 ..	482,955 ..	1,112,650 ..	2,222,003
1895	599,665 ..	497,075 ..	973,586 ..	2,070,326

which shows a decrease for 1895 of 151,677 t., or nearly 7 per cent

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

The shipments of steam coal during the past week reached, notwithstanding the holiday, over 76,000 tons. The demand, now that work is resumed, is fairly good, and prices are steady. The house coal trade remains without change. Tin-plates continue dull, without any alteration in quotations. The iron and steel works are all fairly well employed.

Prices:—Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 10½d.; hematite warrants, 48s. 8d., f.o.b. Cumberland; Middlesbrough No. 3, 38s. 5d. prompt; Middlesbrough hematite, 46s. 1d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails, heavy sections, £4 15s.; light ditto, £5 to £5 5s., f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel cokes, 9s.; Siemens coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C., 18s. 6d. to 20s. Pitwood, 15s. 3d to 15s. 6d. London Exchange telegram: Copper, £45 6s 3d.; Straits tin £60 2s. 6d. Freights steady.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, April 2nd.

RECIPROCITY relations with Central and South American countries so abruptly terminated a short time ago are now meeting with fresh and unexpected support and endorsement in commercial, manufacturing, and financial circles. The incoming administration will take up the issue, and re-enact all the main features. The commercial situation is still unfavourable. The development of trade is slow, although railroad traffic is increasing, and the weekly bank clearings show that there is a much larger volume of business being done. The business situation is far from satisfactory. The iron trade is pretty active. The Lake ore vikings have chased the Bessemer steel people from the seas, and are declaring that 4 dol. ore shall be the only ore that shall be sold, except Meseba and one or two others. Coke is 2 dols. a ton. These figures mean firm and possibly higher prices for all iron and steel products into which Lake ores enter. The plate and tank mills are busy, but structural iron goes slowly. The smaller iron interests are in need of a special stimulus. Building operations are multiplying. Surprises in trade and manufacturing may toss all the present depression to the winds within any forty-eight hours.

LAUNCHES AND TRIAL TRIPS.

On Wednesday, April 1st, 1896, there was launched from the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, a spar deck steel screw steamer, No. 422. Dimensions, 322ft. by 40ft. 6in. by 28in., built to Lloyds' 100 A1 class, and with a deadweight capacity of about 4650 tons. She is built on the deep frame system, with five bulkheads, and cellular double bottom for water ballast. The spar deck is of iron, main deck of steel, and poop, bridge, and forecastle decks of wood, with handsome accommodation under bridge for captain, officers, and engineers. The engines will be supplied by Messrs. Thos. Richardson and Sons, Hartlepool, the diameter of the cylinders being 23in., 36in., 59in. by 42in. stroke, with two large steel boilers. This vessel is sister ship to the On Sang and Ilaro lately built by the same builders.

On Tuesday week last, the large new steel screw steamer Fitzpatric, built by the Tyne Iron Shipbuilding Company, Willington Quay, to the order of Messrs. Burrell and Son, of Glasgow, was taken to sea off the mouth of the Tyne for her official trial trip. The vessel is a very fine type of cargo steamer, having a deadweight carrying capacity of nearly 7000 tons, and her dimensions are 365ft. by 47ft. by 29ft. 9in. moulded. She is fitted throughout with the most modern appliances for the economical working of ship and cargo. The propelling machinery, which has been constructed by the North-Eastern Marine Engineering Company, at the Wallsend works, consists of triple-expansion engines having cylinders, 27in., 43in., 72in., by 45in. stroke, with two large multitubular steel boilers suitable for a working pressure of 170 lb. per square inch. The working of the machinery throughout the trial gave the most satisfactory results. Mr. Stewart, who has superintended the construction of ship and engines, expressed his entire satisfaction with both vessel and machinery. After the trial the vessel proceeded to Cardiff to load for Bombay. This is the fifth vessel the Tyne Iron Shipbuilding Company have recently built for Messrs. Burrell and Son, three of which vessels have been engined by the North-Eastern Marine Engineering Company, at Wallsend. The shipbuilders were represented by Mr. Bone, managing-director, and the engine builders by Mr. S. Hunter.

On the 1st inst. Messrs. Swan and Hunter launched from their yard at Wallsend the first half of the large pontoon dock they are building for the Smiths' Dock Company, of North Shields. This dock, which has been designed to lift vessels of a deadweight of 6500 tons in a space of thirty minutes, is one of Messrs. Clark and Stanfield's well-known off-shore docks, which have been already described in our columns—see December 25th, 1891, and March 14th, 1892—and has been constructed from the designs of this firm. It will be remarkable for the great rapidity with which it will be able to deal with vessels of large tonnage, and also for the fact that electricity is being used as the motive power for the pumps, the current being supplied from the yard installation. The present pontoon will be the second one that the owners have put down, the first having been so successful from every point of view, and when completed, which will be very shortly, it will make this yard the most complete and most modern equipped ship-repairing establishment in the world. Messrs. Lindbergs, of Stockholm, are also fitting their yard with one of these off-shore docks, the first portion of which was launched from their yard on the 28th ult., they being in the present case their own constructors under the supervision of the patentees, Clark and Standfield. The lifting power of this dock will be a little over 2000 tons, the motive power in this case being supplied by oil engines on the dock itself.

ON Tuesday night at Aston Cross, near Birmingham, a tram engine, with car attached, standing near Aston Church, commenced to move without the driver. The conductor was not apprised of the driver's absence until his repeated ringing of the bell failed to stop the car. The engine was rapidly descending Park-road-hill when the conductor applied the brake, but without affecting the momentum of the car, which rushed along at a rate of nearly thirty miles an hour, and dashed with terrific force into an engine and car at the foot of the hill. The runaway engine was smashed to fragments by the force of the impact, the woodwork was set on fire and blazed furiously. There were nine passengers on the runaway car, all of whom suffered more or less from shock. Fortunately most of the passengers had alighted from the standing car, but the engine driver sustained severe injuries, and was removed to the General Hospital. The driver of the runaway engine was charged at the police-court on Wednesday with drunkenness.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

24th March, 1896.

6494. Incandescent Light, W. P. Thompson.—(*The Continental-Gas-Glühlicht-Actien-Gesellschaft "Meteor" vormals Kroll, Berger, and Co., Germany.*)
6495. Cycles, W. P. Thompson.—(*M. Linman, Germany.*)

6584. Glueing the Backs of Books, J. V. Galicher, London.
6585. Igniting Incandescent Gas Lamps, J. F. Duke, London.
6586. Regulation for Incubators, E. L. Godfrey, London.
6587. Billiard Marking Apparatus, J. G. Dixon, London.
6588. Bullets for Rifled Small-arms, W. J. Jeffery, London.
6589. Spoons for Mixing Absinthe, A. J. Boult.—(*L. Rouge, France.*)
6590. Speed Gears, J. W. Hall, London.
6591. Houses, &c., A. J. Boult.—(*S. Elton, United States.*)
6592. Garden Edging and Border, A. W. Davies, London.
6593. Sprocket Chains and Wheels, F. H. Smith, London.
6594. Bottles, E. L. Forsgren, London.
6595. Window Sashes, C. J. Conlon, London.
6596. Puzzles, E. V. D. Rousseau, London.
6597. Toilet Preparations, F. T. James, London.
6598. Bale Ties, E. A. G. Schutt, London.
6599. Augmenting Quantities of Mercury, L. Ehmann and H. Obermayer, London.
6600. Lip Protector for Cigarettes, M. Lumley, London.
6601. Clinical Thermometer Cases, A. E. Dean, London.
6602. Indicating Appliances, A. E. Farrants, London.
6603. Scarifiers, H. F. Rutty, London.
6604. Exhibiting Photographs, A. G. Bessemer, jun., London.
6605. Dress Holders, A. Riddell, London.

26th March, 1896.

6606. An Electric Cyclometer, T. G. Smith, London.
6607. Shifting Spanners, Callipers, &c., F. Mitchell, Surrey.
6608. Parastudio for Photography, W. Watson, Glasgow.
6609. Trellis, F. C. Freeman, London.
6610. Adjusting Cycle Handles, A. P. J. Archbold, London.
6611. Plate Lifter, C. P. Watson, Leeds.
6612. Fishing Reel, A. Allcock, Redditch
6613. T-squares, J. Granz, Manchester.
6614. Manufacture of Bells, F. Bosshardt.—(*R. D. Freres, France.*)
6615. Indicating the Day of the Month, J. Gordon-Smith, Edinburgh.
6616. Violins and other Instruments, A. Shelmerdine, Liverpool.
6617. Copying Documents, &c., E. L. Woodward, Coventry.
6618. Rudder, W. J. Darling and J. G. Walliker, Bristol.
6619. Boots, J. A. Mayo, Bristol.
6620. Attaching Knobs to Doors, F. Parlour and T. T. Harrison, Bristol.
6621. Manufacture of Millboard, G. E. Stead, Manchester.
6622. Boots, G. E. Stead, Manchester.
6623. Loom Pickers, J. Greenwood, Manchester.
6624. Air-tight Receptacles, W. C. Johnson, Bournemouth.
6625. Holder for Telephone Receivers, A. J. Fippard, Bournemouth.
6626. Flexible Hair Curler, G. Adams, London.
6627. Anchors, E. Darby, Lowestoft.
6628. Attachment for Analogous Machine, J. Robins Glasgow.
6629. Badges, F. Sugg, Liverpool.
6630. Bats, F. Sugg, Liverpool.
6631. Folding Perambulator, R. R. Thom, Kilmarnock.
6632. Suspending a Ball of Wool, E. M. T. Huskisson, London.
6633. Lamps, J. Potter, London.
6634. Chain of Fine Steel Plates, H. W. Boucher, Wigan.
6635. Window Fasteners, J. Bryce, Leeds.
6636. Engines, W. H. Griffiths, Liverpool.
6637. Magic-lantern Slide Carriers, A. E. Bingemann, London.
6638. Machine for Cigar Manufacture, O. Wartmann, London.
6639. Connecting the Barrels of Guns, A. Reichwald.—(*Fried. Krupp, Germany.*)
6640. Night Lights, J. A. Glenveere, London.
6641. Ladders, J. Zurek, London.
6642. Construction of Chandeliers, J. Hunt, Birmingham.
6643. Velocipedes, G. D. Warren, London.
6644. Collars, T. A. French, London.
6645. Tooth, Nail, and other Brushes, R. Addis, London.
6646. Clip for Saving Candle Ends, A. O. Morley, Birmingham.
6647. Milk Steriliser, H. M. and J. T. Myers, London.
6648. Mechanism for Looms, A. Gartner and R. Atherton, London.
6649. Shoe Fasteners, E. Compton, London.
6650. Adjustable School Desk, W. L. Starkey, London.
6651. Chemical Composition, P. E. Schoenfelder and E. Kehle, London.
6652. Breeches, H. J. Nicholls, London.
6653. Silk Net, B. J. B. Mills.—(*E. Vial and Co., France*)
6654. Production of Iron, A. Karyscheff and S. Demmanie, London.
6655. Producing Carbonate, The Chemical and Electrolytic Syndicate, Ld., O. J. Steinhart, and J. L. F. Vogel, London.
6656. Savings Box, H. Mecklenburg and W. Quasching, London.
6657. Photographic Apparatus, &c., E. Pothier, London.
6658. Webs, Belts, Straps, &c., F. T. Burrows, Middlesex.
6659. Fluid Engines, R. Christian, and J. and G. Dicken, London.
6660. Pneumatic Tires, W. Fletcher, London.
6661. Pumps, M. W. Hall, London.
6662. Producing Photographic Negatives, F. H. Wood, London.
6663. Maximum, &c., Thermometers, R. A. Grosse, London.
6664. Holders or Clips for Wire, J. G. Flint, London.
6665. Device for Use with Gas Burners, C. Crastin, London.
6666. Type-writing Machines, H. E. Payne, London.
6667. Lock Mechanism for Guns, T. Horsley, jun., London.
6668. Prepayment Gas Meters, W. N. Milstead, London.
6669. Engraving Machines, F. W. Sabel, London.
6670. Houses, C. H. Leonard, London.
6671. Foundations of Lighthouses, A. F. Eells, London.
6672. Tip Parts of Boots and Shoes, G. D. Pike, London.
6673. Applying Starch to Wearing Apparel, A. G Brookes.—(*W. A. H. Henrici, United States.*)
6674. Means for Draining Brushes, W. C. Hawtin, London.
6675. Apparatus for Working Buttonholes, W. Ross, London.
6676. Tubulous Steam Boilers, D. Purves, London.
6677. Buckles, W. Hampson, J. Scott, and H. Vincent, London.
6678. Turbines, W. P. Thompson.—(*O. Lindner, Belgium.*)
6679. Babies' Feeding Bottles, A. Haworth, Liverpool.
6680. Permanent Way of Railways, A. Haworth, Liverpool.
6681. Manufacture of Brushes, C. B. Walker, Manchester.
6682. Cycles, J. T. Whittingslowe, Liverpool.
6683. Domestic Fire Grates, I. Parkinson, Liverpool.
6684. Boots, A. J. Reed, Liverpool.
6685. Insufflator, B. R. Martin, London
6686. Chairs, J. G. McCaffrey and A. D Lenty, London.
6687. Spectacle Side End Cushion, T J. Phipps, Watford.
6688. Apparatus for Mining, T. Parker and Sir J. B. Stone, London.
6689. Warp Guides, &c., T. Wray and J. T. Fletcher, London.
6690. Skate Sharpeners, H. H. Lake.—(*A. D. Banker, United States.*)
6691. Smoke-consuming Furnaces, P. A. Archipenko, London.
6692. Electric Cut-outs, A. B. Blackburn and W. L. Spence, London.
6693. Removing Wrinkles, W. S. Simpson, London.
6694. Cycles, F. S. D. Scott, London.
6695. Securing Railway Rails, M. P. Herfurth and L. Gocht, London.

27th March, 1896.

6696. Self-fastening Knob, J. G. Walthew, Bolton.
6697. Steam Guard Kettle Holder, H. M. Peak, Liverpool.
6698. Brooches, G. Davis and L. H. Bennett, Birmingham.
6699. Umbrellas, Parasols, &c., E. Flude, Leicester.
6700. Cycle Gear, C. Bell, Derby.
6701. Process of Annealing Steel, D. C. Dalzell, Birmingham.
6702. Damping Apparatus, S. R. Armitage and R. Johnson, Manchester.
6703. Compound Machines for Planing, G. Pickles, Halifax.
6704. Pumping Apparatus, P. Poggi.—(*G. M. J. Schedelin, France.*)
6705. Dolly Washing Machine, M. A. Swinburn, Great Grimsby.
6706. Brown Boot Polisher, W. J. Clarke, Great Yarmouth.
6707. Washing Machine, M. Kerr and J. Cunningham, Liverpool.
6708. Blackboards, R. M. Hall, Manchester.
6709. Calculating Instrument, H. E. Gladdum, Manchester.
6710. Cuff Guard and Protector, J. G. Williams, Manchester.
6711. Rail Joint, F. J. Reynolds, London.
6712. Coating Iron, J. Ruffle, Neath.,

6749. Cooling Apparatus for Liquids, H. Krack, London.
6750. Fruit Gatherer, F. C. E. Simon and A. P. L. Launay, London.
6751. Carbons for Electricity, W. P. Thompson.—(*A. Lessing, Germany.*)
6752. Locking Railway Switches, C. H. Schager and J. M. J. Lundin, London.
6753. Drive Chain, A. Appleby, Birmingham.
6754. Boiler Furnaces, W. O. A. Lowe and D. Lister, Liverpool.
6755. Fire-arms, J. W. Lundgren and M. Z. Viau, Liverpool.
6756. Detonating or Shooting Toys, J. Gage, Liverpool.
6757. Manufacture of Viscose, H. Spicer, London.
6758. Feeding Bottles and other Flasks, F. Delas, London.
6759. Tufted Pile Carpets, Henderson and Co., Ld., and R. Britton, London.
6760. Braces for Trousers, J. Guisinde, London.
6761. Drawing Boards, A. J. Boult.—(*A. Schmidt, Germany.*)
6762. Velocipedes, W. D. Hodgkinson, London.
6763. Cooking Stoves, E. B. Parnell, London.
6764. Funnels, E. B. Parnell, London.
6765. Manœuvring Ships, E. Smethurst and J. Knight, London.
6766. Photographic Pressure Frames, L. A. Marion, H. Guibout, G. Bishop, F. Bishop, and J. P. Kirk, London.
6767. Knives and Corn Holders, A. Anderson, London.
6768. Puzzles, W. H. Pepper, London.
6769. Pull-blocks, &c., for Vehicles, S. Parks, London.
6770. Steam Gauge Attachment, H. and W. J. Browning, London.
6771. Bottles, J. Meyer, London.
6772. Mucilage Bottles, J. S. L'Hommedieu, London.
6773. Puzzles, C. A. Edwards, London.
6774. Bicycle Holders, C. E. and M. R. Jewell, London.
6775. Wax Matches, G. D. Day, London.
6776. Elevators, J. S. Mucklé and W. H. B. Teamer, London.
6777. Thrashing-machine Drum, A. Ferri and E. Behles, London.
6778. Manufacture of Cigarettes, H. H. Wills, London.
6779. Treatment of Gold Ore, A. de C. Scott, London.

28th March, 1896.

6780. Platen Printing Machines, A. Carswell, Belfast.
6781. Protector for Heels of Boots, J. C. Tutt, London.
6782. Check Valves, H. Burns, London.
6783. Pneumatic Band, T. D. Bell, York.
6784. Beetle Mountings for Cloth, W. N. Brown and W. F. Reynolds, Antrim.
6785. Pottery Worms, H. L. Doulton, London.
6786. Cycle Pedal, E. Mattei, London.
6787. Flushing Water-closets, C. Church, London.
6788. Disengaging Boats, T. Hudson, Portsmouth.
6789. Controlling Sewage Gas, S. H. Adams and M. J. Adams, York.
6790. Stationery Cabinets, A. E. Mitchell, Bristol.
6791. Photographic Cameras, W. J. Lancaster, Birmingham.
6792. Variable Speed Gearing, W. Bowden and R. J. Urquhart, Manchester.
6793. Eyes of Hoes, R. P. Yates, Birmingham.
6794. Prepayment Gas Meters, J. Anderson, Glasgow.
6795. Explosive Shells, W. G. Hay, Liverpool.
6796. Stench Trap for Waste Pipes, T. Acton, Manchester.
6797. Educational Toy, H. Evans, Manchester.
6798. Needle Knitting Machines, J. W. Watts, Leicester.
6799. Roller Blind Furniture, J. Evans, Manchester.
6800. Boot Polishing Machine, W. H. Green, Southampton.
6801. Roller Forks for Printing Machines, F. Ullmer, London.
6802. Guiding Gasholders, E. L. Pease and Ashmore, Benson, Pease, and Co., Ld., Stockton-on-Tees.
6803. Dressing Woven Fabrics, W. Clark, Glasgow.
6804. Apparatus for Ships' Boats, J. Hamilton, Glasgow.
6805. Photographic Cameras, G. H. Banister, Woolwich.
6806. Machines for Glossing Collars, S. Barrett, Keighley.
6807. Cycle Brakes, M. I. Wilkins, Bristol.
6808. Ammonium Chloride, F. Bale, Droitwich.
6809. Distributing Artificial Manure, E. P. Smith, Gloucester.
6810. Boot Attachment, H. T. Baxter, Dundee.
6811. Preventing Draught in Chimneys, F. T. Huffam, Manchester.
6812. Adjustable Trench Plough, J. Rempl, Berlin.
6813. Golf Ball Net, G. Melville, Glasgow.
6814. Road Vehicles, R. O. Rowland, London.
6815. Window Sash Hanger, J. Browne, Dublin.
6816. Machine Potato Lifter, A. Burns, Ratho, N.B.
6817. Portable Desk, J. H. H. Hogge, W. J. Boniface, and the Pax File Syndicate, London.
6818. File Cases, J. H. H. Hogge, W. J. Boniface, and the Pax File Syndicate, London.
6819. Pad for Moistening Stamps, &c., D. Fulton, Glasgow.
6820. Automatic Vent Peg, W. C. Sanderson and F. C. Cawdell, Barnsley.
6821. Stoppers for Aerated Water Bottles, G. Hirst, London.
6822. Saddle for Cycles and the like, E. R. F. Mason, London.
6823. Measuring and Registering Cloth, J. E. Wilkinson, London.
6824. Drying Shoes and the like, W. V. Wickede, London.
6825. Pianofortes, J. and A. Acock and W. Miller, Blockley.
6826. Cleaning the Meshes of Sieves, T. C. Heath, Liverpool.
6827. Bookbinding, W. Slight, London.
6828. Rails, H. Cane, London.
6829. Centre-finding Instrument, H. Cane, London.
6830. India-rubber, W. J. Clapp and F. S. Dauncey, London.
6831. Propelling Road Carriages, M. W. W. Mackie, London.
6832. Spring Balances, I. A. Timmis and P. Ward, London.
6833. Convertible Cycle Skirt, W. Morford, London.
6834. Horseless Carriages, E. Gascoine and C. D. Courtois, London.
6835. Carbonic Acid Gas, B. T. L. Thomson, London.
6836. Substitute for Celluloid, S. W. Wilkinson, London.
6837. Hair Pins, W. Schwahn, London.
6838. Toys, H. J. Garbutt and G. C. Marks, London.
6839. Castors, R. McLeod, London.
6840. Spring Tires for Velocipedes, L. I. Perry, London.
6841. Cullender, W. G. Hugh, London.
6842. Ornamental Anklet, G. A. Boughton-Leigh, London.
6843. Securing Broom-heads to Handles, E. Nash, London.
6844. Window Fastener, A. V. Fenton, London.
6845. Composing Machines, S. H. and P. E. Hodgkin, London.
6846. Blocks for Ceilings and Roofs, O. Förster, London.
6847. Gas Lamps, W. Katofius, London.
6848. Preparing and Applying Motive Fluid, E. Field, London.
6849. Playing Games of Marbles, G. W. Thomas, London.
6850. Case for Bicycles for Transport, C. A. Pearson, London.
6851. Tool for Driving and Forcing, W. Sellar, London.
6852. Pressing Artificial Fuel, H. C. B. Forester, London.
6853. Making Artificial Fuel, H. C. B. Forester, London.
6854. Gasholders, C. C. Walker, London.
6855. Cleaning and Sorting Water, O. Schmidt, London.
6856. Washing and Bleaching Composition, C. M. Lévy, London.
6857. Coke Ovens, G. Hilgenstock, London.
6858. Solutions of Tetranitro Cellulose, C. D. Abel.—(*E. Bronnert and T. Schlumberger, Austria.*)
6859. Tires for Carriage Wheels, H. W. Brüning, London.
6860. Bottles, A. Lechenich and B. Schomann, London.
6861. Fastening Device, A. Stelzer and E. Schulthess, Brussels.
6862. Bicycles, J. G. Ferguson, London.
6863. Cowls, A. Ransom, Farnham.
6864. Short Circuiting Devices, G. A. Jewett, London.
6865. Assembling Soles of Boots, C. S. Luitwieler, London.
6866. Letter Files, A. Krah, London.
6867. Counting Mechanism, S. Berditschewsky, London.
6868. Automatic Floating Packing, E. T. Ferrier, Cardiff.
6869. Ammunition Chests, J. Ramsay and P. W. Masson, London.
6870. A Portable Bicycle House, A. P. Crouch, London.

30th March, 1896.

6871. Water-closets, W. P. Thompson.—(*J. C. Febiger, jun., United States.*)
6872. Motor for Propelling Vessels, J. Pinkert, London.
6873. Filter Presses, W. E. Heys.—(*J. Hundhausen, Germany.*)
6874. Incandescent Gas Burners, &c., W. R. Clay, Keighley.
6875. Bearings for Shafts, J. Bradbury, Manchester.
6876. Pneumatic Brakes, S. Tweedale and J. Clegg, Rochdale,
6877. Covers for Pneumatic Tires, J. Newhouse, Colne.
6878. Banjos, H. Riley, W. J. Riley, and F. Baker, Birmingham.
6879. Brakes for Cycles, W. H. Sewell and J. Aiken, Glasgow.
6880. Tea and Coffee Save-all, C. Brome, Llandinam.
6881. Wheel for Cycle Gearing, F. J. Smedley, Nottingham.
6882. Wheels for Chains, R. Hutchinson and T. Bowler, Nottingham.
6883. Mowing Machines, H. P. Saunderson, London.
6884. Pneumatic Tires for Cycles, F. W. Willcox, Sunderland.
6885. Tool Holder or Cutter Bar, C. Ferguson, Cromarty.
6886. Washing Machines, J. W. and G. T. Shepard, Cheltenham.
6887. Extracting Cyanides from Dust, R. Addie, Glasgow.
6888. Box Irons, J. A. Perks and S. Allen, Birmingham.
6889. Keyboard Appliance for Pianos, S. Suckley, Sheffield.
6890. Distributing Currents, S. Berditschewsky, London.
6891. Ashlar Block for Walling, &c., C. Wall, London.
6892. Carrying Off Obnoxious Fumes, A. H. Sach, London.
6893. Copying Books, F. G. Fender and W. Coleman, London.
6894. Tobacco Pipes, R. Whittaker, London.
6895. Spinning Frames, &c., A. V. V. Wichelin, London.
6896. Coin-freed Apparatus, G. Knight and G. Ellis, London.
6897. Preventing Re-filling Bottles, F. Rovedino, London.
6898. Bale Tie, J. Knott, London.
6899. Finger Support for Pencils, &c., H. Lombard, London.
6900. Bottle Stopper, W. Millar, London.
6901. Muzzles for Dogs and other Animals, A. Wood, London.
6902. Steam Traps, E. A. Adams, London.
6903. Jointing of Pipes and Tubes, J. W. Wyles, London.
6904. Automatic Water-tight Door, J. W. Graydon, London.
6905. Locks and Latches for Doors, H. T. Poate, London.
6906. Extensible Chair or Seat, W. Nordberg, London.
6907. Frames for Photographs, &c., E. Griffiths, London.
6908. Flower Pots, A. Young, London.
6909. Vertical Turbines, J. G. Marshall, London.
6910. Driving Mechanism, T. Hann, W. Bromley, J. Price, A. H. Smith, and D. E. Radclyffe, London.
6911. Tins for Preserved Meats, &c., A. Maconochie, London.
6912. Typewriting Machines, J. C. Fell.—(*Wyckoff, Seamans, and Benedict, United States.*)
6913. Embossing Lithographed Sheets, D. Price, Hanley.
6914. Shades and Screens, A. H. Synge and C. E. Challis, London.
6915. Motor Cycles and the like, W. Hildebrand, London.
6916. Saddles, G. Beckett, Liverpool.
6917. Locks and Lock Gates of Canals, A. Johnson, Manchester.
6918. Envelopes, J. E. Dohen and W. H. Grace, London.
6919. Making Combustible Gas, J. E. Dowson, London.
6920. Preservation of Meat, C. L. Villar, London.
6921. Extracting Metals from Ores, O. Frölich, London.
6922. Production of Illuminating Gas, V. B. Lewes, London.
6923. Compressing Hay, C. T. and W. B. Burgess, London.
6924. Curing Stinking Casks, T. Middleton and C. A. Verner, London.
6925. Electric Water Gauge, &c., H. Biermann, London.
6926. Securing Tires to Wheel Rims, R. Corsham, London.
6927. Cigar and Ash Holders, G. F. Prendergast, London.
6928. Valve for Liquid Pumps, J. S. Porter, London.
6929. New Pharmaceutical Product, S. Fränkel, London.
6930. Treating Acetylene, J. C. Mewburn.—(*A. C. Fraser, United States.*)
6931. Bicycles, P. L. Girardet, London.
6932. Moquette Fabrics, P. A. Newton.—(*W. B. Smith, United States.*)
6933. Explosion Engine, W. Hornsby, R. Edwards, D. Roberts, and J. Young, London.
6934. Filtering Material, F. Jurschina, Z. Schnitzer, and F. Hirsch, London.
6935. Rotary Pumps, H. Morris and F. Bastert, London.
6936. Kitchen Dressers, F. Mann and H. H. Akers, London.
6937. Explosives, W. Greaves and E. M. Hann, London.
6938. Briquette-making Apparatus, F. J. Müller, London.

31st March, 1896.

6939. Pocket Knives, J. M. Moss and W. Smith, Manchester.
6940. Pumps for Railway Air Brakes, G. S. Lee, Birmingham.
6941. Governor for Railway Air Brakes, G. S. Lee, Birmingham.
6942. Valve for Railway Air Brakes, G. S. Lee, Birmingham.
6943. Electric Light Door Switch, W. J. Fryer, London.
6944. New Cover for Pudding Basins, H. Wood, London.
6945. Carriage Steps, J. Whitehead and J. A. Crane, Birmingham.
6946. Reversing Gear for Engines, A. H. Truelove, Blackpool.
6947. Brushes and Brooms, H. Coombs and W. C. Seager, London.
6948. Ploughs for Cleaning Land, A. J. Lyon, Cambridge.
6949. Reversible Window Sashes, J. Shaw, Willington-on-Tyne.
6950. Fixing Tips on Cues, G. E. Cockle and S. Kyle, Clontarf, Co. Dublin.
6951. Water Trap, B. R. Phillipson, Dublin.
6952. Mechanical Horse for Riding, C. Blackmore, Bristol.
6953. Willeys for Wool, &c., H. and W. Morton, Leeds.
6954. School Slate, Drawing Board, &c., W. H. Friend, Rye.
6955. Curtain Holder, P. Philpot, Birmingham.
6956. Mantel Shelves, &c., P. Philpot, Birmingham.
6957. Roller Bands, W. and J. Richardson, Birmingham.
6858. Controlling Gear for Trucks, J. D. Bell, Glasgow.
6959. Machine for Treating Fabrics, H. C. Longsdon, Keighley.
6960. Construction of Valves, D. P. G. Matthews, Newport, Mon.
6961. Wheel Tires, J. E. Rogers, Birmingham.
6962. Self-closing Umbrellas, A. Kortenbach, Manchester.
6963. Drawing Scales, T. Jackson, Leeds.
6964. Arrangement of Torpedo Screws, F. R. Mazzinghi, Birmingham.
6965. Water-closets, E. A. Green, Sheffield.
6966. Soles for Boots and Shoes, F. T. Lehmann, Cologne.
6967. Looms, J. Fallenschmid, Cologne.
6968. Connecting Metal Pipes, A. Fletcher, jun., Glasgow.
6969. Railway Chairs, J. Paterson, Glasgow.
6970. Railway Signal Wires, T. J. Phipps, Watford.
6971. Railway Guide, T. Fox and T. F. Shepherd, Barnsley.
6972. Envelopes, J. M. Young, Glasgow.
6973. Shuttle Guard, J. Monk, J. Lang, and J. Catterall, Preston.
6974. Engines, J. S., R. D., W. D., and H. C. Cundall, Halifax.
6975. Shuttle Guards for Looms, &c., F. Baynes, Halifax.
6976. Hair-brushes, F., W. S., E., and H. Claughton, Leeds.
6977. Photographic Printing Frames, W. Tylar, Birmingham.
6978. Tobacco Pipes and Holders, J. R. Boulcott, Birmingham.
6979. Weaving Turkish Towelling, W. H. Hacking, Manchester.
6980. Boat Propeller, J. Entwisle.—(*S. N. Smith and E. S. Baring-Gould, United States.*)
6981. Electric Batteries, J. Entwisle.—(*S. N. Smith and E. S. Baring-Gould, United States.*)
6982. Screw-cutting Machines, F. Cornil, Brussels.
6983. Leather Horseshoe, P. Prince, Brussels.
6984. Water-tight Doors, J. W. Proctor, Manchester.
6985. Gas Meters, J. Hawkyard and J. Braddock, Manchester.
6986. Stokers, F. Clayton, Manchester.
6987. Method of Packing Meat, &c., S. M. Okell, London.
6988. Fire Extinguisher, H. A. Mansfield, Birmingham.
6989. Holder for Geographical Maps, I. Uschakoff, Glasgow.
6990. Mud-guard for Cycles, &c., W. Nicholls, Birmingham.
6991. Supporting Railway Tracks, F. Lessner, London.
6992. Raising Vessels, F. Kindt and J. C. Davis, London.
6993. Coin-freed Electric Meter, R. Hacking, London.
6994. Consolidated Soups, T. F. Garrett and W. M'Spouse, London.
6995. Holdfast, F. Rowbotham, Manchester.
6996. Bracelets, E. Murrle.—(*E. Kun, Germany.*)
6997. Heating Food, J. Bohensky, London.
6998. Fasteners for Shoes, W. L. Judson and H. L. Earle, London.
6999. Horizontal Coke Ovens, &c., A. Hüssener, London.
7000. Potassium Chloride, L. Epstein and F. Marza, London.

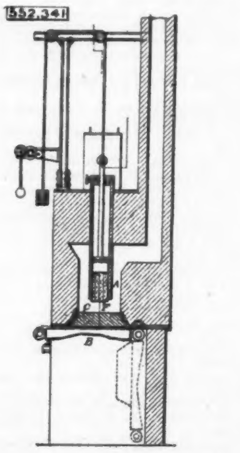
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

552,341. Electric Smelting Furnace, *J. A. Vincent and J. E. Hewes, Philadelphia, Pa.—Filed July* 18*th*, 1895.

Claim.—(1) In an electric smelting furnace, the combination of the hearth, with a removable bottom constituting one of the electrodes, an adjustable electrode arranged above the bottom and movable vertically, and feeding devices at the upper part of the hearth or furnace for delivering the materials to be smelted into the hearth. (2) In an electric furnace, the combination of the hearth A, the movable bottom B having the electrode C closing the bottom of the hearth, the vertically adjustable electrode F, the inclosing shield I surrounding the electrode F, a flue L between the shield and wall of the hearth, and feeding devices for feeding the materials to be smelted into said flue L. (3) In an electric furnace, the combination of the hearth A having a gas flue opening from its side walls, the movable bottom B having the electrode C closing the bottom of the hearth, the vertically adjustable electrode F, the inclosing shield I surrounding the electrode F, a flue L between the shield and wall of the hearth and above the gas flue, and feeding devices for feeding the materials to be smelted into said flue L.

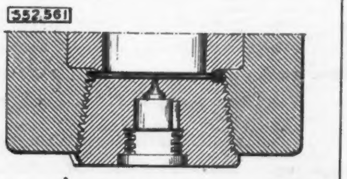
552,341



552,561. Screw-threaded Breech Block, *A. Welin, London, England.—Filed September* 16*th*, 1895.

Claim.—(1) The combination of a tapering breech block, a corresponding breech opening, a divided screw on the block such that the front face of each of the threads makes a greater angle with the axis of the block than the rear face, and a corresponding screw in the breech. (2) The combination of a tapering breech block, a corresponding breech opening, a divided screw on the block having the front face of each of its threads at right angles to the axis of the block and the rear face inclined thereto, and a corresponding screw in the breech.

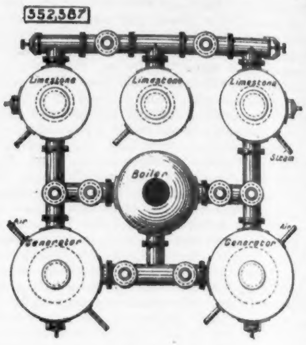
552,561



552,587. Cupola Gas-making Apparatus, *J. M. Rose, Allegheny, Pa.—Filed March* 16*th*, 1888.

Claim.—(1) A gas-making apparatus having a central boiler, two separate cupola gas generators on one side of said boiler and having valve controlled pipe connections therewith, and a series of casings containing auxiliary gas generating or treating chambers on the other side of said boiler having valve controlled connecting pipes, and valve controlled connecting pipe between the end chambers of said series and the cupola generators, substantially as and for the purposes set forth. (2) A gas-making apparatus having a central steam boiler, two generators on one side of the same, a series of casings containing connected auxiliary gas generating or treating chambers on the other side of the boiler, and valve controlled pipe connecting pipes between the end chambers of the series, and the boiler and generators, substantially as and for purposes set forth.

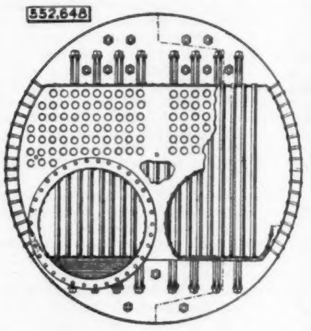
552,587



552,648. Steam Boiler, *C. Starke, Milwaukee, Wis.—Filed November* 26*th*, 1894.

Claim.—In a marine boiler of the so-called "Scotch" type, a combustion chamber flat at the top and bottom but otherwise circular, a series of vertical tubes in said chamber extending through the top and bottom of the same, and a deflector extending rearward from the front wall of the aforesaid chamber below horizontal flues through which products of combustion find their escape.

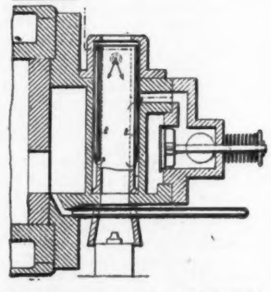
552,648



552,686. Petroleum Oil Engine, *J., S., F., and E. Carter, Billingshurst, England.—Filed April* 17*th*, 1895.

Claim.—In an explosive engine, the combination with a heater, and a tube for carrying off the products of combustion, of a sleeve surrounding said tube and forming a vaporising chamber between it and said tube, said vaporising chamber being provided with ribs *t*, *t* for causing the oil to pass over the whole surface of the heater; means for supplying oil to said vaporising chamber, an air inlet adjacent to the oil inlet to admit air to allow circulation of vapour in the vaporiser so as to empty the vaporiser on out stroke of piston, a mixing chamber in communication with said vaporising chamber, an air supplying pipe for said mixing chamber and an igniting device passing through the said tube, substantially as described.

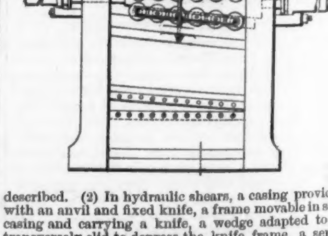
552,686



552,710. Hydraulic Shears, *E. A. W. Jefferies, Philadelphia, Pa.—Filed September* 27*th*, 1895.

Claim.—(1) In a hydraulic shears, a casing provided with an anvil and fixed knife, a frame movable in said casing and provided with a knife, a transversely slidable wedge, two series of connected rollers, one series being interposed between the wedge and casing and the other between the wedge and knife frame, both series of rollers moving slightly in the same direction in which the wedge is slid, and means for actuating said wedge, substantially as and for the purposes described. (2) In hydraulic shears, a casing provided with an anvil and fixed knife, a frame movable in said casing and carrying a knife, a wedge adapted to be transversely slid to depress the knife frame, a series of rollers connected together and interposed between the wedge and knife frame, a series of rollers connected together and interposed between the casing and wedge, said two series of rollers travelling slightly in the same direction in which the wedge is slid, means for operating said wedge and means adapted to counterbalance said knife frame and to return the same when not depressed by the wedge, substantially as and for the purposes described,

552,710



"THE ENGINEER"

1100 GUINEA ROAD-CARRIAGE COMPETITION.

On the fifth of July last we announced that the sum of 1000 guineas would be given by the proprietors of The Engineer by way of prizes for the encouragement of manufacturers and designers of horseless carriages, believing as we did that an important trade could be created in this class of machinery, and that the removal of the restrictions on the use of mechanically-propelled vehicles would result in great benefit to our farmers. As our readers are aware, we followed up this announcement by the circulation of a memorial to the President of the Local Government Board, praying for the introduction of a Bill for the amendment of the law—a memorial which was very extensively signed, and which was laid before the President, accompanied by some suggestions, invited by him, as to the form the Bill should take. The Bill has been introduced and printed in our columns. It is framed—as we ventured to hope it would be—very much on the lines we suggested. In the month of November, and, of course, before the Bill was prepared, we thought it right to publish certain preliminary conditions to enable designers and manufacturers to set to work. These conditions prescribed four classes of vehicles, and, as they have no doubt been acted upon, no change can fairly be made in them. As the law then stood, and as it stands at the present moment, the use of "light" oil or spirit is practically prohibited, because of the onerous conditions laid down by Statute for its carriage and storage, and for that reason vehicles using petroleum spirit were excluded from our competition. As, however, we gather from the Bill now before Parliament that a change in the law may be made in this respect, we have determined to admit to the competition vehicles using the hitherto prohibited spirit, and as no departure could be made from the published conditions, we have determined to offer a "supplemental" prize of 100 guineas for competition amongst vehicles of this class. The full conditions as now finally settled are given below.

The Crystal Palace has been selected as the centre from which the vehicles competing for the prizes offered by The Engineer will start, and to which they will return at the end of their long run. The Crystal Palace is well adapted for the purpose. The grounds of the Palace contain miles of gravelled roads with hills and levels, on which minor trials can be carried out by the judges with much convenience. The building is perfectly accessible, and well known to the whole world. There is ample room, and competitors will secure all the publicity they can desire.

CONDITIONS OF COMPETITION.

Note.—*These are drawn up on the assumption that the present restrictive Legislation will cease to be in force prior to the date of the Competition, and that a new Act of Parliament will have been passed giving greater facilities. It may be, however, that this new Act will not allow of all the following Conditions remaining exactly as now set forth, and they may possibly have, when the Legislation is complete, to be modified. If, unfortunately, the state of the law should make it impossible, in the judgment of the Proprietors of* The Engineer, *to hold the Competition as at present contemplated, no blame or responsibility shall attach to them or the Judges, or to the Crystal Palace Company.*

The Proprietors of **The Engineer** have agreed with the Crystal Palace Company, who have offered facilities at the Crystal Palace for showing the carriages in work there, and for holding the subsidiary trials hereafter referred to.

Judges.

The following are the names of the judges:—

Sir Frederick Bramwell, Bart., F.R.S., M. Inst. C.E.

Mr. John Audley F. Aspinall, M. Inst. C.E., Chief Engineer to the Lancashire and Yorkshire Railway.

Dr. John Hopkinson, F.R.S., M. Inst. C.E.

The competition is to be international.

Classes.

The vehicles will be divided into four classes, and one supplemental class, in each of which a prize will be given, as follows:—

A.—For the best mechanically propelled vehicle constructed to carry—including the driver—four or more persons, the total weight, when fully loaded, not exceeding two tons, a prize of **350 Guineas** will be given.

B.—For the best mechanically propelled vehicle constructed to carry either one or two or three persons, the total weight, when fully loaded, not exceeding one ton, a prize of **250 Guineas** will be given.

C.—For the best mechanically propelled vehicle constructed to carry, in addition to the driver, not more than 1 ton of goods, or parcels, the total weight, when fully loaded, not exceeding 2 tons, a prize of **250 Guineas** will be given.

D.—For the best mechanically propelled vehicle constructed to carry, in addition to the driver, 5 cwt. of goods or parcels, the weight, when fully loaded, not exceeding 1 ton, a prize of **150 Guineas** will be given.

Supplemental.—For the vehicle, whether for passengers or goods, propelled solely by a motor actuated by the vapour of oil or spirit, having a lower specific gravity than 0·8, or a flashing point lower than 73 deg. Fah., Abel's test, and constructed to satisfy the requirements of any Act of Parliament, and the rules to be made thereunder for the time being respectively in force, which, in the opinion of the judges, best satisfies the purpose for which it is built, a prize of **100 Guineas** will be given.

The judges are to have the power to divide any prize in case of vehicles proving of equal merit.

Propelling Power.

Any method of propulsion other than muscular power may be employed, provided it be contained in the vehicle.

Quality of Oil for Power Purposes.

Except in the Supplemental Class, no oil or other liquid used in any engine, whether for the production of an explosive mixture, vapour, or for fuel, shall have a lower specific gravity than 0·8, or a lower flashing point than 73 deg. Fah., Abel's test.

Entries.

Entries are to be made on printed forms—to be obtained at the offices of The Engineer—at any time prior to 6 p.m. on the last day of July, 1896, being forwarded by registered letter, addressed to the Editor of The Engineer, 33, Norfolk-street, Strand, W.C., and accompanied by a deposit of £1 for each entry; this deposit will be forfeited if the vehicle entered is not submitted for competition.

Delivery.—Description and Descriptive Drawings.

The competing vehicles must be delivered at the Crystal Palace, Sydenham, between the hours of 10 a.m. and 6 p.m. on some day prior to 2nd of October next. Prior to the delivery of each of the vehicles, there must be forwarded to the Editor of The Engineer, 33, Norfolk-street, Strand, W.C., a docket showing the weight of the unloaded vehicle, in complete running order, with its store of fuel and water—if these are to be used—this docket being furnished by a weighmaster of some public weighing machine. At the same time there must be forwarded six, at least, type-written or printed descriptions of the machines, setting out, as briefly as possible, any peculiarities of construction or of working to which the competitors desire to draw the attention of the judges, and also six sets of clear blueprint drawings or sketch tracings, to a scale of not less than 1½in. to the foot, illustrating the construction. These documents will not be returned, but on their receipt, a printed Form of Request to The Crystal Palace Company, to accept delivery of the vehicle, will be forwarded to each competitor by the Editor of The Engineer, and this Form of Request will have to be produced to the authorities at Sydenham when the vehicle is delivered.

Opening-up of Machines.

After delivery, and before the practical working run, hereinafter referred to, each vehicle is to be opened up by a skilled attendant representing the competitor, in the presence of one or more of the judges, or their representative, for their information.

Preliminary Runs.

Preliminary runs in the grounds of the Crystal Palace will be made with each of the vehicles in succession by the competitors in the presence of the judges or of someone representing them.

Practical Working Run.

This will consist of a run on the public roads of not less than 100 miles out and 100 miles home, or a total of not less than 200 miles over a course to be announced three days prior to that fixed for the run. It is impossible at present to fix the exact date for this run, but it will probably be arranged for Monday, the 12th day of October next. On starting for this run from the Crystal Palace, each vehicle is to be fully loaded and is to have its full store of fuel and water—if these are used—and is also to carry the number of adult passengers for the class in which it is entered, one of whom is to be a representative of the judges, who will be counted as part of the load.

Route Map.

There will be provided for each competitor, on making application at the office of The Engineer three days before the practical working run commences, a route map indicating the course which it is suggested the vehicles shall take, but the competitors will be free to take any road they think proper between the Crystal Palace and their destination and back.

Order of Starting.

Lots will be drawn to determine the order in which the vehicles are to start. It is intended that the first shall leave at or about 10 a.m., and the remainder at intervals of ten minutes. During the run the representative of the judges shall keep, on a printed form which he will have with him, a "log" of the run.

Change of Drivers.

Any competitor may change his driver at any place *en route*, if he should think proper.

Inspection of Vehicles on Return.

After the return of the vehicle to the Crystal Palace, it shall again be opened up by the competitor and submitted to the inspection of the judges, or their representatives, and this prior to anything being done to the vehicle in the way of repair or renewal, except such as may have been effected during the run.

Further Runs.

Should the judges so determine, further runs are to be made on subsequent days by all or any of the vehicles in the premises of the Crystal Palace Company or on the public roads.

Disqualification.

The judges reserve to themselves the right of absolutely disqualifying any vehicle or competitor from the competition for any infraction of these rules, or for any cause whatsoever, and without in any way being bound to state the reason or reasons for which such disqualification is made.

Number of Vehicles to be Exhibited by each Competitor.

No competitor, either directly or by any agent or otherwise, is to enter for competition two similar vehicles in any one of the classes above referred to; and each vehicle is to be entered by not more than one person, that is to say, in the name of one individual or firm.

Responsibility.

While obeying in all respects the instructions of the judges, it is to be fully understood and agreed by every competitor that no responsibility, legal or otherwise, is to attach either to the judges, to the proprietors of The Engineer, or to the Crystal Palace Company in respect of anything, or for any damage or injury caused to any person or thing, but all responsibility of every sort and kind, whether pecuniary or otherwise, is to attach to the competitor, and is to be borne by him.

Length of Practical Working Run.

Any vehicle which does not complete the "practical working run" at a minimum average speed of five miles an hour, to include all stoppages, shall be disqualified. The distance upon which such time allowance will be computed will be fixed by the judges and stated on the route map.

Note.—*As the attainment of high speeds is not one of the objects sought, it has been determined that nothing in speed over ten miles an hour will be placed to the credit of any competitor, but, subject to this condition, the competitors may go as they please, at any speed they think proper, running continuously day and night, or stopping as they think best.*

The following are the points which will be taken into consideration by the judges in awarding the prizes:—

(*a*) Distance run without stop for any purpose whatsoever, or without taking or receiving supplies of fuel, oil, gas, electrical, or chemical materials or electrical current or of whatever is employed for actuating the motor. Freedom from stoppages for repairs, adjustment, or for oiling or any other purpose or cause.

(*b*) Suitability of design and excellence of workmanship, not only of the actuating machinery but of the carriage.

(*c*) Safety.

(*d*) Simplicity, durability, accessibility and facilities for repairs and absence of offensive smells.

(*e*) Time occupied in getting to work and ease of starting.

(*f*) Speed (up to ten miles per hour) and hill climbing.

(*g*) Completeness of control by and certainty and decision of steering and steering gear, and efficiency and durability of brakes and brake gear.

(*h*) Weight of carriage and motor machinery and appliances.

(*i*) First cost and (to a limited extent) the cost of working.

(*j*) General efficiency.

Note.—*The quantity of fuel, oil, gas or power-giving material or electricity used during the long duration run will not be specially taken into account, although observations will be made by the judges on this subject; but trials of short duration of the vehicles selected for further tests will be made if deemed necessary for the purpose of ascertaining the cost of working of the vehicles.*

Judges' Decision to be Final.

The decision of the judges expressed in writing on any point shall be final and binding on all parties, and from such decision there shall be no appeal.

COPY OF RULES TO BE FURNISHED TO EACH COMPETITOR AND SIGNED BY HIM.

Three printed copies of these rules will be supplied to each competitor or his accredited representative, and no competitor will be allowed to deliver his vehicle at the Crystal Palace until he has signed one of these copies, and it has been handed in to the Editor of THE ENGINEER and formally acknowledged and accepted by him. In signing and forwarding this copy of these rules the competitor shall accept all the conditions herein imposed upon him, and shall agree to be bound in all respects by them.

OFFICIAL NUMBER AND STAMP ON VEHICLES.

Prior to the start for the long-distance competition there will be attached to each vehicle, in some convenient place, a card stamped with the judge's seal and bearing upon it the number assigned to that particular vehicle for the purposes of the competition. The seal must not be broken, otherwise the vehicle will be disqualified.

PARAGRAPH TO BE SIGNED BY COMPETITORS.

I agree to abide, and be bound, by the above rules and conditions, or any modifications of them which the judges may think desirable or necessary.

Signed..

THE FAILSWORTH SEWAGE PURIFICATION WORKS.

THE formal opening of the Failsworth Sewage Outfall Works took place on Thursday, April 2nd. The ceremony was attended by a large company, and was presided over by Mr. Councillor Wild, J.P., Chairman of the District Council. Mr. Councillor Dunkerley, chairman of the Sewage Committee, declared the works open. Mr. C. J. Lomax, A.M.I.C.E.—Messrs. Lomax and Lomax, Manchester and Bolton—is the engineer who has carried out the scheme. Messrs. Freeman, of Hollinwood, are the contractors, the process adopted being the "International."

The Outfall Purification Works which have been constructed embody all the latest improvements in sewage treatment, and are on a scale which will ensure the continual and successful treatment of the sewage. The sewage enters the outfall works at an elevation of 12ft. above the water level in the tanks, advantage being taken of the fall by utilising the water power for chemical mixing purposes and other minor work. Sufficient power is also obtained to work an air compressing engine which will supply the necessary power to a ram for elevating the sewage from the few houses situate somewhere about 35ft. below the water level in the tanks. The sewage passes from the mixing house into two detritus tanks. The action of the precipitant "ferozone," which has been previously mixed with the sewage, shows itself to a striking degree in these tanks. The sewage passes out by troughs into six upward-flow tanks, and the degree of clarification that takes place in these tanks is excellent; from the tanks the effluent passes on to the 6in. polarite filter beds. The filter beds adopted are on an entirely new system, the patent rights being the property of the International Water and Sewage Purification Company, Limited. In the ordinary method of filtration the beds are in the first instance slowly filled up until about 1ft. of water stands upon the surface, the process of filtration then commences. The water in passing through the bed is exposed to the purifying action of the oxygen contained in the atmosphere, but the available oxygen in the bed is rapidly exhausted, and so long as a head of water is kept upon the surface of the bed, it is physically impossible for the air to penetrate into the interstices of the filtering material. To overcome this difficulty the International Company is now using a new process, Failsworth being the second successful installation. The filter beds, being six in number, are grouped three on each side, with a central inlet channel dividing them. This inlet channel is of sufficient capacity to cover the filter beds 3in. in depth with water.

Each bed is supplied by two automatic flushing syphons, which discharge the water from the inlet channel in the space of about thirty seconds over the entire area of the filter; the water then sinks through the bed and disappears in about five minutes. The flow of water to the inlet channels is so regulated that it takes exactly twenty minutes to fill and discharge, therefore the filter bed is entirely empty and exposed to the atmosphere for fifteen minutes out of every twenty. Three inches of water spread over the surface every twenty minutes is equal to 1000 gallons to the square yard in twenty-four hours, and this is the speed at which the Failsworth filter beds are now working.

By the intermittent method of filtration purification is obtained not only by direct oxygination, but also by the organisms that have been proved to rapidly increase in the beds. The effluent as it leaves the filter beds is clear and sparkling, devoid of froth on shaking, and is free from odour. The area of the filter beds is 960 square yards. One singular feature in the intermittent filtration is, that whilst this large volume of water is being rapidly flushed upon the bed not one particle of sand is disturbed from its place.

THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—At the meeting held on Thursday, April 9th, a paper was read by Mr. A. Hanssen, C.E., on the "Commercial Efficiency of Steam Boilers." This was an exceedingly interesting paper, the author having been at considerable trouble to collect and tabulate, not only the cost of a number of various classes of boilers, but the cost of their settings, flues, and chimneys; and having ascertained their capital value and their average life, he compared the sums that it was necessary to set apart annually, to recoup the owners for the capital originally invested in them, at the termination of their average lives. The question of the use or otherwise of economisers, to be used in connection with boilers for the raising of steam, was also entered into; and the discussion that took place after the reading of the paper was directed very largely to this point. The president, Mr. S. à Court, A.M.I.C.E., was in the chair; and among those who took part in the discussion were C. T. Walrond, E. H. G. Brewster, Chester Dawson, D. Allport, A. F. White, and B. G. Willmott.

NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. V.—CURVES OF STABILITY.

IN the third paper of this series it was shown that B N—Figs. 13 to 16—or the perpendicular distance from the centre of buoyancy in the upright condition to the vertical, through the centre of buoyancy in the inclined condition of the vessel, is the arm of the lever at which the weight D of the displacement acts at that angle of inclination, when the centre of gravity coincides with the centre of buoyancy. In other words D × B N is the moment of the vessel's surface stability, or the stability due to her form alone at that angle.

It was further shown that when the centre of gravity does not coincide with the centre of buoyancy, as is almost always the case, then D × G Z is the moment of statical stability at that angle.

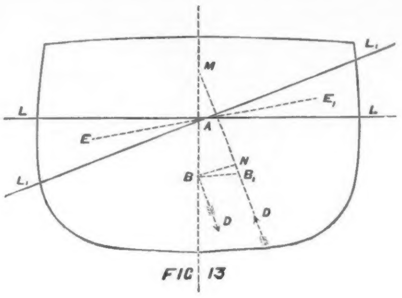

FIG 13

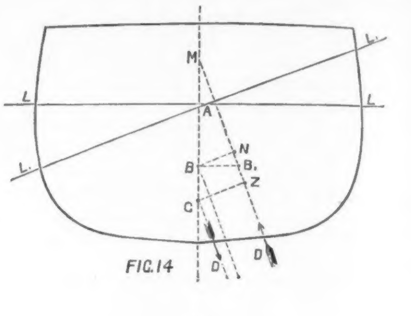

FIG. 14

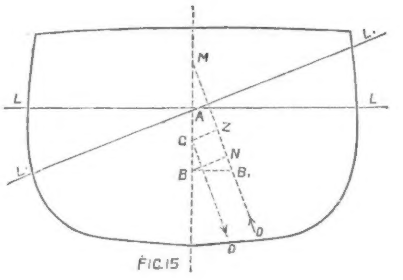

FIG. 15

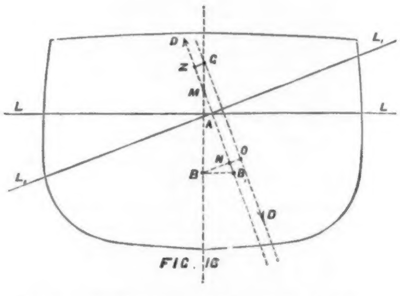

FIG. 16

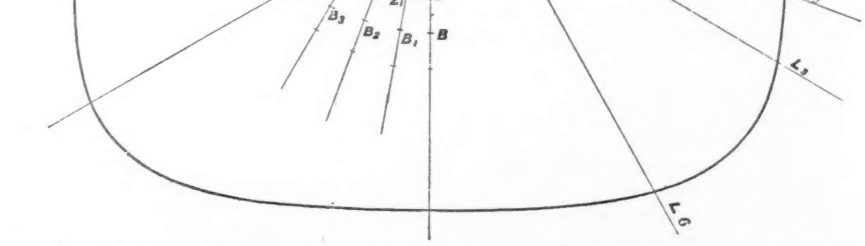
Again, referring to Figs. 13 to 16, it will be observed that when G is below B, then G Z is greater than B N, and when G is above B, G Z is less than B N. Finally, when G is above the transverse metacentre M, then G Z becomes negative, and the moment is an upsetting one.

Ordinarily G is above B, and throughout a large angle of inclination from the upright G is below M; or, rather, M is above G, for M is the variable point while the vessel is being inclined.

Let us now consider a specific vessel—see Fig. 21—with her centre of buoyancy in the upright position situated at B, and her centre of gravity at G; her load water-line under these conditions is L L.

Fig 21.



We will now incline this vessel through a small angle—say 10 deg.—when her load water line appears as L_1 L_1. This inclination is accompanied by a certain transference in the position of her centre of buoyancy, the extent of which may be calculated by a method alluded to in the second article of this series, but which is of too intricate and laborious a character to admit of description in these elementary papers. Let B_1 be the altered position of B at the 10 deg. inclination, and let G Z_1 be the perpendicular distance from G to the vertical line through B_1.

Again, incline the vessel through another 10 deg., so that now her total inclination from the upright is 20 deg. Let L_2 L_2 be the load water-line at this inclination, B_2 the centre of buoyancy, and G Z_2 the perpendicular distance from G to the vertical line through B_2. Once more incline the vessel through another 10 deg., so that now her total inclination from the upright is 30 deg. Let L_3 L_3 be the load water-line at this inclination, B_3 the centre of buoyancy, and G Z_3 the perpendicular distance from G to the vertical line through B_3.

Also let M_1, M_2, M_3, &c., be the various successive positions of the transverse metacentre at these angles of inclination. These will be almost coincident at first, but as the angles of inclination increase the positions of M will vary more considerably.

To avoid confusion we have omitted in Fig. 21 the load water-lines at 40 deg. and 50 deg., but have drawn L_6 L_6 the load water-line at 60 deg. inclination. The centre of buoyancy at that angle is B_6, the metacentre is M_6, and G Z_6 is the perpendicular from the centre of gravity upon the vertical through B_6.

This figure shows us the arms of the righting couples at 10, 20, 30 and 60 deg. of inclination; and if we further drew the nine water-lines at intervals of 10 deg. between the upright and the 90 deg. inclination, also the nine positions of the centre of buoyancy and metacentre, as well as the nine values of G Z ranging from G Z_1 to G Z_9, we would have on our diagram the materials for constructing a curve of stability.

Turning to Fig. 22, we have a horizontal line divided up into a number of equal divisions—or abscissæ—of 10 deg., and at its left-hand extremity we have a vertical scale of feet.

At the 10 deg. division on the horizontal line an ordinate has been set up representing the value of G Z in feet at that inclination, as determined by calculation for a certain vessel. Similarly at the 20 deg., 30 deg., &c., divisions, values of G Z in feet are set off, as determined by calculation for the corresponding angles of inclination. These values in this particular case increase up to an inclination of about 50 deg., after which they rapidly diminish until at an inclination of 80 deg. G Z becomes zero. That is to say, the righting leverage in this instance increases up to an angle of inclination of about 50 deg., where it is a maximum; it then diminishes continuously, until at an inclination of 80 deg. the vessel ceases to possess any righting moment, and from thence capsizes. The curve A B C drawn through the extremities of the ordinates given by values of G Z at the several angles of inclination of the vessel, is termed a curve of stability. As will be seen by comparing Figs. 21 and 22, the values of G Z in the former are not nearly so instructive regarding the stability of the vessel as when plotted in the manner shown by the latter figure, and then represented by a curve. Moreover, the curve of stability affords us values of G Z at all the intermediate inclinations between 10 deg. and 20 deg., 20 deg. and 30 deg., and so on.

But the graphical representation of the vessel's stability, as in Fig. 22, is even still further instructive if we duly consider it. This will be seen by reference to Fig. 23, which shows the curves of stability of several vessels so superimposed as to show the conditions of stability of each relatively to the others.

The curve marked *a* commences with a direction making a greater angle of inclination to the base line than either of the other curves. This indicates that the vessel to which it refers has high initial stability, due to M being at a greater height above G than in the vessels to which the other curves relate. This may be in consequence of the centre of gravity being unusually low; but more probably it results from M being unusually high. If the latter is the true explanation then the vessel is doubtless broad in proportion to her volume of displacement.

It will further be noticed that the maximum stability is attained at an angle of only 20 deg. of inclination, at which the value of G Z is about 1ft. 6in. From this it is evident that the vessel has a very low freeboard, so that an inclination of but a few degrees from the upright is sufficient to bring her gunwale below water, and that when an inclination of 20 deg. is passed so much of the upper works are submerged as to result in further inclinations being attended with a diminished value of G Z, until at about 45 deg. the latter becomes zero, and the vessel is on the point of capsizing.

These peculiarities of the curve of stability *a* in Fig. 23 point to the fact that the vessel is of such a form as that of the monitors employed in the American Civil War, or of the floating batteries built for our own navy for service in the Baltic forty years ago.

The curve indicated by letter *b* in Fig. 23 shows slightly less initial stability than *a* with a maximum value of G Z at about 35 deg., and a vanishing value at 79 deg.

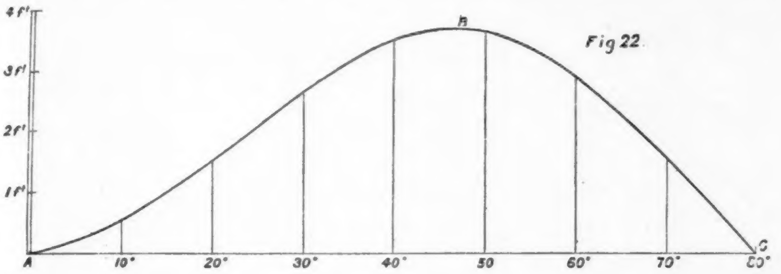


Fig 22

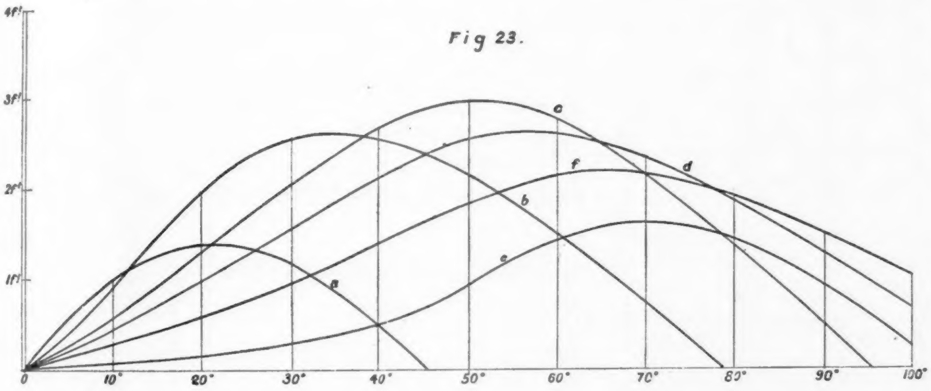

Fig 23.

This vessel has also a comparatively large G M, due probably to considerable breadth in proportion to her depth and length, as well as to a low position of the centre of gravity. She has, however, a much higher freeboard than the vessel previously considered, although her upper deck is not so high above the water-line as in the cases of *c* and *d* curves.

In both cases the vessels are doubtless uneasy rollers, and require large bilge keels to make them at all steady in a seaway. But while great breadth of beam was essential for safety in the case of the vessel shown by curve *a* in view of her low freeboard, the high initial stability was not so necessary in the case of *b*, which has sufficiently lofty sides to give her a range of stability extending to an inclination of nearly 80 deg.

The vessel, of which *c* is the curve of stability, has better sea-going qualities than either of the other two. In her case the maximum righting moment is not reached until the vessel is inclined to an angle of 50 deg. from the upright, and it is not until an inclination of more than 90 deg. is attained that her stability wholly vanishes. Of course, in supposing such large angles as these, it is understood that all openings in the deck and sides of the vessel are hermetically sealed against the admission of the sea. Moreover, the vessel is supposed to be heeled over in still water and not among waves.

The vessel, of which *d* is the curve of stability, is perhaps the most desirable sea-going type of the four. She has comparatively small initial stability, and is therefore an easy roller. Her maximum stability is not attained until an angle of 58 deg. is reached, in which condition the value of G Z, while less than in the *c* curve, is yet sufficient. But, best of all, her range of stability is such that at 90 deg. the value of G Z is the same as at 25 deg., and a state of instability is not reached until the vessel is heeled over to nearly 110 deg.

The curves marked *e* and *f* relate to the same vessel, but in different conditions of lading and immersion. The curve *e* represents the vessel when in the light condition; that is to say, without any cargo on board, while *f* is the curve of stability when loaded and ready for sea. This is a steamer with a comparatively low metacentric height, but with an awning deck which gives her a high freeboard. Hence her centre of gravity being lowered when the cargo is in, she has in that condition a greater initial stability than when her cargo holds are empty. In both cases she has a high range of stability, but is comparatively "tender" or "crank," and therefore readily inclined from the upright.

From what has been said, it will be evident that curves of stability present to the eye of an expert very important facts in relation to the sea-going qualities of the vessel to which they refer. A naval architect would not dream of giving sail power to the vessel represented by *a*, and would be very reluctant to employ her on any but coasting or harbour duties. On the other hand, *c* and *d* curves show that the vessels to which they relate are fit to carry sails, and so far as stability is concerned, to go anywhere.

But not only does the naval architect seek to know the condition of stability of a ship when at her load immersion, and with the cargo stowed so as to give a mean or average position of centre of gravity, it is often his further aim to learn something about the vessel's stability at different angles of inclination, when at lighter draughts of water, and even when in ballast trim. Hence it is no uncommon thing to find curves of stability drawn corresponding to successive depths of immersion, and their corresponding positions of M and G. During recent years several expedients have been devised for simplifying the calculations necessary to determine the movements in the position of the centre of buoyancy, due to inclining the vessel through successive angles when at different draughts of water. The particulars of these devices are of too intricate a character to admit of description in these articles; it must be sufficient to say that, thanks to the common use of mechanical calculating appliances, such as the planimeter and integrator, in our shipyards, and the simplification of methods to which allusion has been made, not only can curves of stability be calculated in about one-tenth the time occupied on such work a quarter of a century ago, but the results are also attended with greater accuracy and fuller detail.

With the facilities now possessed for determining curves of stability for the different conditions of a vessel's immersion and lading, there should be no difficulty in providing such particulars for every ship that leaves her builder's premises. Nor should there be any difficulty in instilling into the minds of shipmasters precisely what these curves are able to teach to those who will consult them. Probably the time will come when such knowledge will be demanded of all master mariners, and when all vessels will carry not only charts of the seas they will traverse, but also charts showing their conditions of stability under different conditions of loading and immersion.

THE COAL PRODUCTION OF FRANCE IN 1894.

The total quantity of mineral fuel raised in the mines of France in 1894—for which the official returns have lately appeared—was 27,417,000 tons– metric—being 1,766,000 tons, or about 7 per cent., above the production of 1893; the different classes of minerals making up this amount being:—

Coal..	25,599,000 tons	93 per cent.
Anthracite	1,365,000 ,, ...	5 ,,
Lignite	453,000 ,, ...	2 ,,
	27,417,000 ,, ...	100 ,,

The value at the pit's mouth was £12,310,400, or £520,000 above that of 1893.

Nearly the whole of the increase was due to increased productivity in the mines of the northern basins—Nord and Pas de Calais—which together furnish about 57 per cent. of the whole output, in the form of gas coking, steam, and house coals. Anthracite is got principally in the North Burgundy and Alpine districts, and lignite in Provence, nearly the whole being obtained from Fuveau, in the neighbourhood of Marseilles.

The largest individual producers, with an output exceeding 1,000,000 tons, were the mines of the following companies, all of which, with the exception of Blanzy, are in the northern basin:—Anzin, 2,826,000 tons; Lens, 2,287,000 tons; Courrières, 1,497,000 tons; Blenzy, 1,411,000 tons; Vicoigne-Noeux, 1,087,000 tons; Bethune, 1,069,000 tons; Bruay, 1,020,000 tons. Eleven other companies raised more than half-a-million tons each, the individual amounts ranging between 502,000 tons and 871,000 tons.

The deepest pits are at Salles de Gagnieres (810 metres), in Gard; Plat de Gier (777 metres), Villebœuf (650 metres), and Comberegol (606 metres), in the Loire; Montchanin (710 metres), Epinac (648 metres), and Blanzy (533 metres), in the Centre; and Anzin (700 metres), Courcelles (636 metres), and Drocourt (620 metres), in the North. The average depth of the workings is, however, considerably less, the principal output being obtained above the 500 metres level.

In the northern basins, which are the most productive, the seams are thin, but this is compensated by their large number. At Anzin there are sixty-six in all, averaging 32 inches in thickness each. At Alais the average is 4¾ft., and at Saint Etienne 9¾ft. At S. Eloy there are two seams, each of 82ft., and at Aubin one of 98½ft.

The number of hands employed in the different classes, both underground and at surface, was:—

	Men.	Youths. 16—18.	Boys. 13—16.	Women.	Totals.
Underground	86,400 ..	5,500 ..	4,500 ..	— ..	96,400
Surface ..	27,600 ..	2,500 ..	4,400 ..	3,700 ..	38,200
Total ..	114,000 ..	8,000 ..	8,900 ..	3,700 ..	134,600

There was an increase in the number of men employed underground to the extent of 2700, but the surface hands have decreased by 800, the latter being principally women and older youths, while the younger hands have increased by about 300. Female labour is now considerably restricted in the French collieries, women not being allowed to work more than eight hours daily, and that only between the hours of 9 a.m. and 5 p.m. The only night work permitted to them is in the lamp room, in which case they must not make more than seven hours' time in the twenty-four hours.

The average wages paid were for miners 4·37f.—3s. 6d.—and for surface hands 3·15f.—2s. 6d.—per day; the former averaging 280 and the latter 288 days at work in the year, giving 1278f.—£50 14s.—and 939f.—£37 5s.—as the annual earnings in each class. The annual output was 285 tons per underground hand, and 204 tons on both surface and underground men taken together, giving an average of 5·80f.—4s. 5d.—as the wages cost per ton of coal.

The selling price averaged 11·12f.—8s. 10d.—per ton taken at the pit, and 19·53f.—15s. 6d.—per ton delivered to the consumer. The extreme range in prices varied with the distance from the mines; the manufacturers in the north getting their coal at about 8s., while in the Jura and Alpine districts, owing to the long railway lead, as much as 30s. was paid. The domestic supply was not sufficient to meet the whole demands of the country, and required to be supplemented by foreign coal to the extent of 11,664,000 tons, 42 per cent. of which quantity, or 4,893,000 tons, was obtained from the United Kingdom. Nearly £500,000 was paid in customs duties upon the coal imported.

Peat is produced in the valleys of the Somme and other northern rivers, but owing to the wet season the yield fell off 174,000 tons in 1893 to 132,000 tons in 1894, the average value being 13·54f.—12s. 10d.—per ton. A considerable proportion of this is, however, used for stable litter and other than heating purposes.

BRITISH ASSOCIATION OF WATERWORKS ENGINEERS.

The establishment meeting took place on the 11th inst., at the Westminster Palace Hotel, under the presidency of Mr. D. M. F. Gaskin, M. Inst. C.E., Nottingham. Representatives were present from all parts of the country, including London, Birmingham, Birkenhead, Widnes, Oldham, Batley, South Staffordshire, Devonshire, Kent, Suffolk, Yorkshire, and Somersetshire.

The Chairman congratulated the meeting upon its representative character, and submitted a draft copy of constitution and rules for the management of the Association, which had been drawn up by a provisional committee. It was pointed out that the object of the Association would be to promote and facilitate the interchange of information, ideas, and practice amongst its members on all matters pertaining to waterworks undertakings, and the mutual advantage of water authorities and consumers; to invite from the members and others communications, written or oral, relating to waterworks engineering, management, and finance, and to receive, hear, and discuss such communications at meetings of the Association or elsewhere; to invite the exhibition of, and to exhibit at meetings of the Association or elsewhere, any new or improved machinery, apparatus, plans, drawings, or models calculated to advance the knowledge of waterworks engineering and management; to assist the Legislature, public bodies, and others in ascertaining the views of persons engaged or interested in waterworks undertakings; to originate and promote improvements in the law, and to support or oppose alterations therein, in all matters relating to waterworks; to watch over, promote, and protect the mutual interests of its members; and to provide facilities for promoting and maintaining, professionally and socially, a spirit of fraternity amongst its members. One of the objects of the Association, and by no means the least important, will be to appoint examiners and to hold examinations. The Association is to consist of three classes—members, associates, and hon. members; and the council will have power to establish a graduate class for pupils of waterworks engineers, and to elect candidates upon such conditions as they may deem advisable. Hon. members will be persons of distinguished scientific attainments whose knowledge on matters relating to water and water supply recommend them to the council. They are to be nominated and elected by the council, and are not to exceed twelve in number. The affairs of the Association are to be managed by a council of members, consisting of a president, two vice-presidents, ten members, and an honorary secretary and treasurer; and annual and general meetings are to be held at such times and places as the council may consider desirable.

The rules having been agreed to, with slight verbal alterations, Mr. Gaskin was elected the first president; Messrs. H. A. Hill, M. Inst. C.E., South Staffordshire Waterworks Company, and W. Matthews, M. Inst. C.E., Southampton, vice-presidents; and Mr. W. G. Pierce, Richmond, hon. secretary and treasurer. The council of ten, elected by ballot, are Messrs. Priestly, Cardiff; Woodward, Wolverhampton; Roberts, Ipswich; Watts, Oldham; Jones, Chesterfield; Richardson, Birkenhead; Leggett, London; Terry, Sheffield; Sandeman, Plymouth; and Bowker, Mid-Kent. It was resolved that the first annual gathering of the Association, which will take place at the end of July or the beginning of August, should be held in Nottingham. The meeting will occupy three or four days, and will cover presidential address and reading of papers, excursions, and visits to and examination of works. At a subsequent meeting of the council, Mr. W. H. Brothers, of Birmingham, was appointed general secretary. The offices are at Palace Chambers, 9, Bridge-street, Westminster.

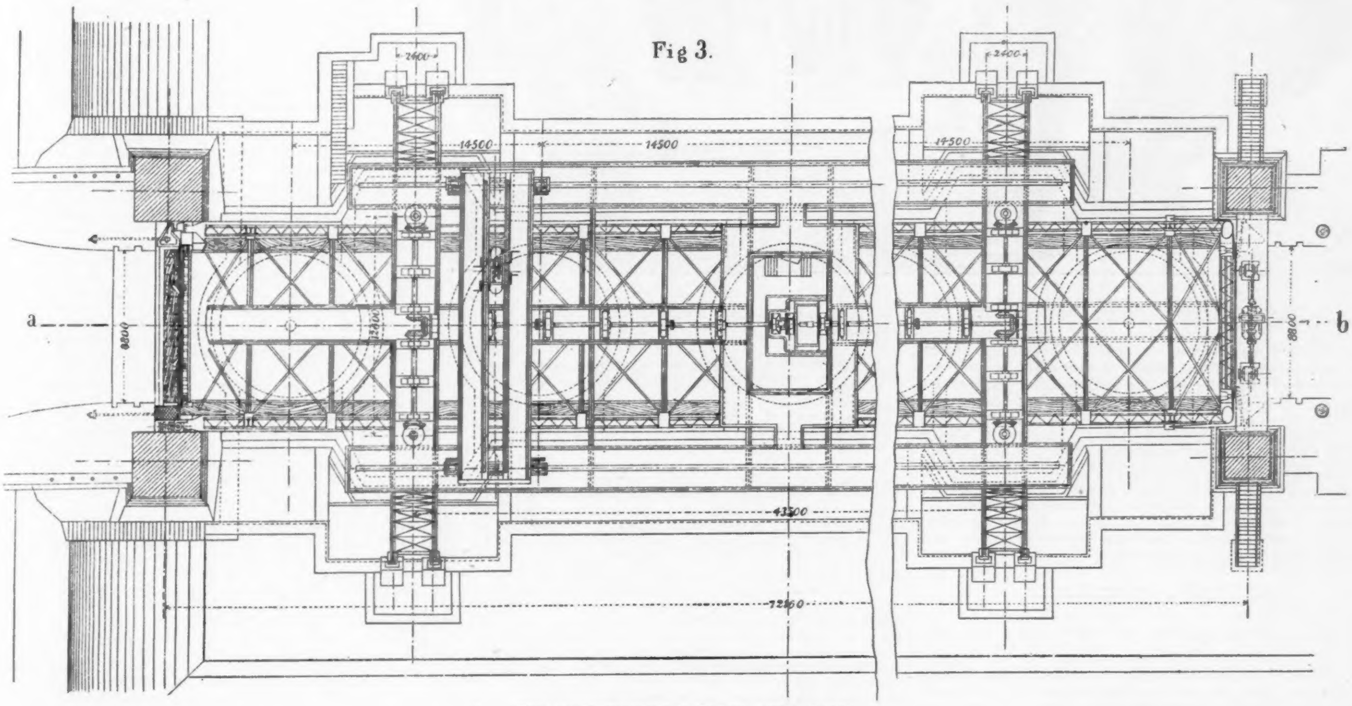
THE HEINRICHSBURG CANAL LIFT.

ON the new canal joining the Port of Emden with the Westphalian coalfield, the Dortmund district is reached by a branch about ten miles long, which joins the main line at Heinrichsburg, but at a higher level. This difference, in amounting to a maximum of about 52½ft., is to be overcome by a floating lift, which is represented in the illustration on page 388. The lifting power is derived from a series of five large floats moving in water-tight pits below the level of the lower canal, which carry the boat trough or cradle, and are made to rise or fall by adding or removing water to the trough to the extent necessary to overcome or reduce the upward thrust. The trough is made to move horizontally by running upon guide screws at the four corners of the framing, provision being also made for driving these screws from a central motor, so that the lift can be effected mechanically in the event of shortness of water or other accidental causes putting the hydrostatic balance out of use. The cradle, which is 239ft. clear length, 28¼ft. broad, and 8ft. 2in. deep, taking a boat of about 600 tons carrying capacity, is carried between two bridge girders, which are connected by lattice framed pillars with the floats below. The weight of the ironwork in these parts is about 1400 tons, and that of the water in the trough 1650 tons, giving a total for the moving weight of rather more than 3000 tons. The work, which has been undertaken by Messrs. Haniel and Lueg, of Düsseldorf, was begun in the spring of 1894 with the excavation of the basin for the cradle, and the sinking of the pits for the floats. These are of the uniform dimension of 30ft. 3in. diameter, 92ft. deep, with the distance of 46½ft. from centre to centre, leaving a rib of solid ground 17ft. wide between each. In order to disturb the solid ground as little as possible, the sinking was carried out simultaneously, the excavation being secured by a water-tight lining put in in short lengths as the ground was cut, so as to avoid exposure to the atmosphere. The first curb put in, about 10ft. down, is a cast iron ring which carries a 32in. wall of rammed concrete extending to the surface, while the top ring line of cast iron tubbing is attached to it below. This tubbing is made up of rings 5ft. high, divided into sixteen segments, with planed faces and flanges, and worked together by screw bolts with strips of lead packing in the joints, each ring being built in and backed with cement as soon as a sufficient depth of ground was excavated for placing it, so that no timbering or other obstruction was necessary. The bottoms of the pits are lined with inverts on concrete, forming spherical segments of 24ft. 8in. radius, the ends of the floats being dished to the same curvature. A 4in. horizontal bore hole lined with an iron pipe connects the whole line of pits at their lowest point, in order to ensure equality of water level in all of them.

Fig 3.



THE HEINRICHSBURG CANAL LIFT—PLAN

The sinking was completed in February, 1895, in about seven months' working time, giving an average progress of about 65ft. per month, the total contents of the ground excavated being about 15,000 cubic yards. The floats, 26ft. 3in. in diameter, 33ft. 9in. high in the cylindrical part, and about 42ft. 8in. including the curved ends, are built of mild steel plates from 0·72in. to 0·8in. thick, stiffened by twelve vertical stringers with intermediate horizontal struts, the former being of H and the latter of Z section, but no internal framing is used, in order to keep down the weight. The design of these floats has necessitated special experiments, as the existing data were not sufficient to determine the proper thickness to be given to the plating, the structures being of exceptional size, and intended to bear a pressure of nearly 100ft. of water.

The boat trough or cradle is built of plates of varying thicknesses, the upright sides being from 0·4in. to 0·56in., while in the bottom 0·32in. buckled plates are used in the middle, and 0·64in. flat ones at the sides; the whole being stiffened at intervals by cross bearers. The bearers are attached to the main girders of the lift by flat bars, giving an elastic connection so that each part may expand independently of the other. This is a point of importance, as in bright sunshine the girders are likely to elongate more than the water-cooled trough so that the rivetted seams of the latter would probably draw if the two were rigidly connected.

The trough is closed at each end by a vertical sluice gate moving on roller guides, a similar gate being placed at the end of each of the canal levels, and wedge-shaped packing pieces fixed to the ends of the trough, which bear against similar pieces on the canal end, form a water-tight joint when the trough is in position for transferring a boat. The small clearance space between the two doors is filled with water by a paddle from the canal gate, and when the level is established the two doors are locked and lifted together by the same motor. The clearance water for the upper level runs into a pipe below the cradle, where its weight is utilised in lowering the boat, and is finally discharged into the bottom canal at the other end.

The most interesting and important feature in the design, the guide screws, intended to ensure the regularity of the movement of the cradle, are attached by collar bearings to lattice frame standards at the corner of the lift, as shown in the transverse section on page 388. They are made of mild steel of 30 tons tensile strength, and 14 tons elastic limit, the maximum strain likely to be brought on them of 595 tons each, representing about 9½ tons per square inch. The total length is 80ft. 9in. and the diameter 11·2in., with a 4in. hole bored through from end to end. The screwed portion, 57½ft. long, carries a double thread 1·4in. deep, with a rise of 1 in 8. The guide nuts on the trough are made of gun-metal in two parts, each 5ft. long, enclosed in a steel plate casing. In order to keep the screws in longitudinal tension and prevent sagging, the top collar bearing is carried on a hydraulic press ram, acting upwards under the constant strain of a small accumulator. A further provision is made against bending by four sliding collars, which are moved in pairs by the trough, so that there can never be more than one-third of the length of the screw unsupported. It is intended to enclose the screws in a casing with hinged doors, opening from the passage of the nuts and closing automatically by sprigs, in order to protect the thread against dust and other disturbing influences. As the screws would, in the event of the trough being emptied, have to bear the whole upward thrust of the floats, or about 1600 tons, the pillars carrying the lower bearings are very securely anchored in pits about 8ft. square, filled with concrete, as shown in the dotted lines in the cross section.

The excess weight required to lower the trough against the thrust of the floats is about 30 tons, or about 2in. depth of water in the trough, in which case the screws only act as guides. They are, however, geared together by bevel wheels and shafting at the top, so that they can be driven by an electro-motor carried on the top of the framing above the lift, by an expenditure of 60 to 80-horse power. With sixty revolutions of the screw per minute, the trough is moved at a uniform speed of about 20ft. per minute, or 2½ minutes for the entire lift, so that allowing time for the accessory operations of warping in and out, the boats may pass through at intervals of about fifteen minutes each. The opening and shutting of the sluice gates and the working of the warping capstans are also effected by an electro-motor of about 100-horse power, the current being provided by a dynamo driven directly by a steam engine of 220-horse power, with three water-tube boilers placed in an engine-house adjoining the lift, which will also be provided with the necessary pumps for drawing the float and for feeding the high level canal.

It is expected that this lift, which will probably be completed at the end of the present year, will be much more economical in working than those depending upon hydraulic presses for balancing power. The total cost is estimated at about £112,000.

OPENING OF THE NEW MIDLAND RAILWAY STATION, GLOUCESTER.

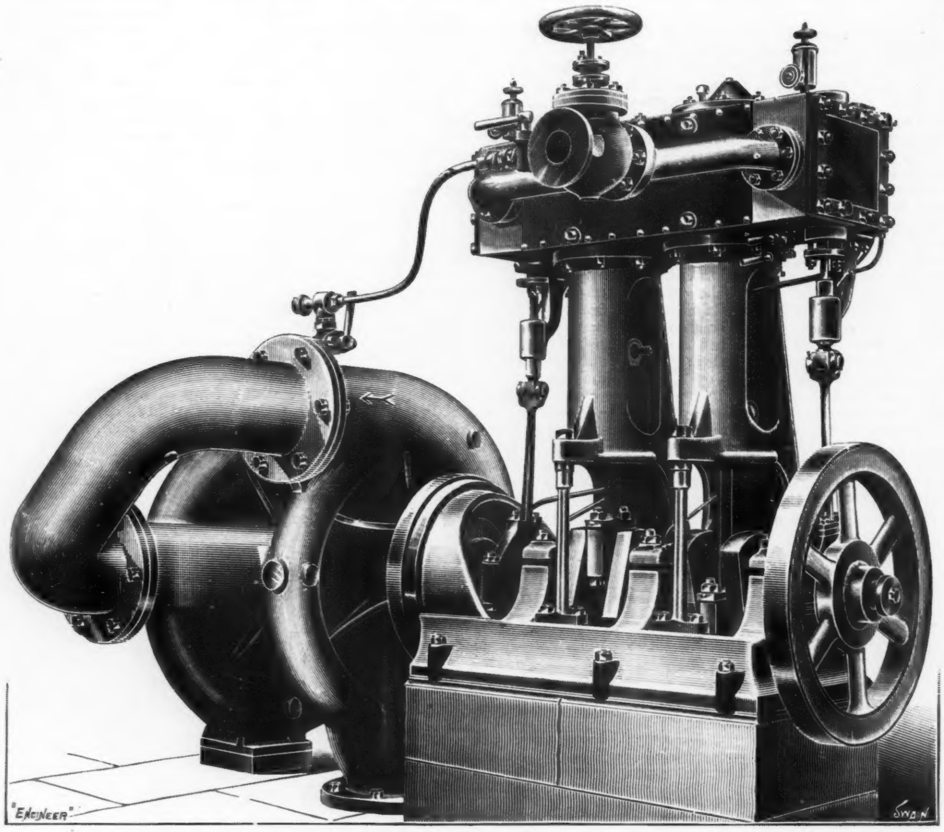
THE new Midland Railway station, Gloucester, was formally opened for all future traffic on Sunday. The new and handsome structure has been built on the site of the old engine and wagon sheds, the work being commenced in January, 1895. The architecture is of modern design, and the buildings are in three blocks—the main block and two sets of waiting and refreshment rooms and offices on the up and down platforms. The station front is 147ft. long, and is built of red pressed bricks with terra-cotta facings. A balustrade runs the whole length of the building, ornamented with panels bearing the railway company's shield. A tower has been erected up to the roof, and the original design was to extend the tower, and place in it a three-faced clock. This may yet be done. The platform frontages of the buildings are of pressed brick with Bisley stone dressings. They are covered with glazed awnings, those projecting from the waiting-rooms being built upon the cantilever principle, thus increasing the platform area, which is 40ft. in front of the main block and 16ft. off the waiting-rooms. The interior of the main block consists of an entrance 40ft. by 18ft., the walls being of buff glazed bricks, and the roof of iron, with ornamental spandrils and glazed rough plate glass. The booking hall is 40ft. by 28ft. The joinery work throughout is chiefly carried out in varnished pitch pine. Most of the ceilings of the halls and offices are fitted with lantern lights. At least two-thirds of the glazing is on the Meliowe's system. The booking-office is 40ft. by 15ft. Leading from and adjoining this department are the clerks' and station master's offices, a cloak-room 32ft. by 20ft., and a parcels office 42ft. by 20ft. A porters' room, lamp room, and other offices have yet to be built to complete the main block. Situated north-east of the new block are the up and down platform waiting-rooms, &c., which in size and number are in keeping with the general substantial and liberal character of the work. On the up platform is a telegraph office 23ft. by 19ft., with a battery room beneath. This department is fitted with ten instruments and three telephones, and is illuminated with Wenham lights. On the up platform is a handsomely appointed dining and refreshment room 52ft. long by 18ft. wide, with a mosaic floor and tiled walls in different patterns. There are four platforms in all, between 700ft. and 800ft. long. These are connected by an iron bridge with Hawkesley patent treads, and when complete will be provided with hydraulic lifts, supplied by Messrs. Armstrong, Mitchell, and Co., for luggage. This bridge, which has been erected by the Horsley Company, Greatbridge, is being extended on stone piers to the Great Western Railway Station, a distance of about 190 yards. It is 14ft. wide, and some of the spans are 136ft. long, the girders weighing about 26 tons each. The girders are 11ft. deep, and are of the lattice strutt type. The roof will be covered with panelled sheeting. The iron work connected with the station has been supplied by Messrs. Grimson and Co., Leicester.

The contractors are Messrs. J. Walker and Sons, Wirksworth, Derbyshire; Mr. C. Trubshaw is the architect, Mr. J. A. Macdonald the engineer, and Mr. T. Wright clerk of the works for the railway company. Much of the work is at present in a very rough and incomplete state, and will not be finished until the autumn, but until the old lines were converted it was impossible to progress with the work. The last train to make use of the old metals at the Barton-street curve, Gloucester, was the 5 a.m. Scotch express, and as soon as it had passed into the old Midland Station, gangs of men in readiness commenced to deflect the lines at that point, and connect them with the new route. The departure of the 7.40 a.m. train for Birmingham was the signal for closing the old station, and the 8.40 a.m. train for Bristol saw the opening of the new station for all future passenger trains. The work of the men engaged—some 300—was continued the greater part of the day in completing connections ready for the Monday's ordinary and heavy traffic. Under the full and efficient management provided everything passed off without a hitch, and no delay to trains was occasioned. The signalling had all to be re-arranged, and two new signal-boxes erected, the north-east box, prepared on Sunday, containing forty levers. The signalling work was carried out under the direction of Mr. Woodward, the company's signalling engineer. The telegraph wires had also to be re-arranged under the superintendence of Mr. Langdon. The lines of the old station will be used as carriage sidings. The new station will enable four trains to be dealt with at the station at one time, and they will not have to back in and out of the station as formerly, but will pass direct through Gloucester. It is contemplated eventually to divide and amalgamate express trains in the new station, which has hitherto been done at Cheltenham. It is estimated the entire cost of the new buildings, the engine shed, and other work contemplated in connection with the present station, will be little short of £100,000. The old Midland Station was opened for traffic in 1840.

JUMEAU, who has for many years been the chief engineer of French India, in the Franco-Indian Public Works Department, has retired on a pension. As his successor, Gurree, the deputy chief, and Fontaneilles, an engineer lately sent out from France to superintend the construction of the Karikal-Peralom Railway, have been mentioned.

DIRECT-ACTING CENTRIFUGAL SERIES PUMP AND ENGINES

MESSRS. JOHN AND HENRY GWYNNE, ENGINEERS, LONDON.



CENTRIFUGAL SERIES PUMP AND ENGINES.

THE illustration shows a vertical double-cylinder steam engine and two centrifugal pumps in series, all driven from one spindle and connected directly to the engine crank shaft. It is suitable for working against heads of 100ft., and will be found to possess many advantages over pumps of reciprocating type. The construction of the pump is simplicity itself; it has no valves, air-vessels, vibration, nor obstruction whatever, and the water passes through it in one continuous stream. It will be found to possess the merit of cheapness in first cost, and the annual charge for repairs is almost nil. By combining the pumps in series, the lift can be augmented to 150ft. We need scarcely add that the workmanship and material leave nothing to be desired.

FOREIGN COMPETITION IN THE IRON TRADE.

THE British Iron Trade Association's report on foreign competition was once more the subject of discussion before the South Staffordshire Institute of Iron and Steel Works' Managers, at Dudley, on Saturday last, when a paper dealing more particularly with practical suggestions upon the matter was read by Mr. H. M. Punnett, of Punnett, Thompson, and Co., galvanised iron manufacturers, the Cape, Smethwick, near Birmingham. Mr. Punnett was understood to voice the views of the Midland Iron and Steel Wages Board, of which he is a prominent member. The chair was occupied by Mr. W. Rubery—of W. P. Parkes and Co., Tipton Green Chain and Anchor Works, Tipton—President of the Institute.

The secretary, Mr. W. H. Carder, announced apologies for non-attendance from several members of the Commission.

Mr. H. M. Punnett said that whatever the general opinion might be as to the completeness of the report of the delegation of the British Iron Trade Association to the Continent, there could be no doubt as to its importance to both employers and employed. In truth, the facts recorded, however short they fell of that which the practical man might desire, were of the greatest interest, and provided them with matter for serious reflection. The delegation was organised by the British Iron Trade Association, but the Midland Iron and Steel Wages Board had long perceived the necessity of arousing the trade of the Midlands to inevitable changes in methods, and gladly joined in the work. As finally arranged, the combination of the several branches of the iron and steel trades gave an almost national interest to the report. At the same time the comprehensiveness of the task created difficulties in finding suitable men able to be absent together, and the large number of delegates compelled a somewhat hurried glance at a subject which required slow and careful investigation. They in Staffordshire, the centre of the sheet iron trade, had on this latter point a right to express some disappointment, for a careful examination of the appendices to the report showed that only three establishments were visited in which either iron or steel sheets were being rolled—one in Belgium and two in Germany. Further, in each of these three cases, the sheet mills were simply supplementary to extensive iron and steel plants, and were in no sense parallel to one of the South Staffordshire sheet rolling mills. It would not, therefore, be doing any injustice to say that conclusions drawn from such a very limited field of inquiry must be accepted with great caution. We all knew that Germany had several great iron centres. The delegation confined its attention to one of those areas only, that of Rhenish-Westphalia, a district which has been aptly described as the "home of the aristocracy of labour in Germany," and he did not hesitate to say that if the inquiry had been extended to the other six important iron producing centres in that country the conclusions drawn would have been very different. In support of that statement, it was only necessary to quote the report issued by our Consul-General, Sir Charles Oppenheimer, in 1893, entitled "Labour Times and Labour Wages in Germany." From that report he extracted the following figures, being the average yearly wages paid to skilled workmen in the seven districts where either iron or steel, or both, are made on a large scale.

	£	s.	d.
Rhenish-Westphalia forge and rolling mills ..	50	2	0
North-Western iron and steel industries	44	14	0
North-Eastern	44	4	0
South-Western	42	3	0
Southern	41	17	0
Saxony Thuringia	41	8	0
Silesian	30	6	0

So much for the assertion he unhesitatingly made that the report hardly touched the fringe of the great question of foreign competition. It was not, however, his purpose in that paper to criticise the report so much as to offer some practical points for consideration, and despite what he said as to the limited area examined by the delegates, it was a matter for congratulation that they selected works of the most efficient kind, and replete with every modern appliance, since they had put before them clearly what was being done, and could be done, by modern machinery, suitable material, and good workmen. Mr. Punnett said he must here ask them to remember that in his following remarks on the works visited he should confine himself to the sheet mills and forges attached thereto. The only sheet mills visited in Belgium were at "A" works, where they were told the costs of coal and pig iron were very much the same as in this district. The puddlers there, as well as in most parts of the Continent, were paid day wages, and the average was about 5s. per day. The quantity puddled per turn was rather more than with them. The hammer men and forge bar rollers earned also about 5s. per day. The wages costs, therefore, of puddled bars was much under that of England. The report added that this was somewhat due to the character of the pig used, and after saying this, one regretted that an analysis of it was not given. As to the quality of the puddled bar, the evidence was difficult to understand. Mr. Trow said, "If the iron had either been hammered or squeezed equal to ours there would have been another 7½ per cent. waste on the puddled bar;" whilst of the sheets, he said "the quality of the pig enables them to put on a superior finish," from which they must conclude that, although the puddled did not seem to him clean, it was good enough for a highly finished superior sheet commanding a very high price. One naturally asked, why, even if possible, make it better? Surely the highest art in economical manufacture was to produce a quality sufficiently good for the purpose to which it was to be applied. This remark of Mr. Trow's reminded him of the criticisms on that most interesting paper read before the Iron and Steel Institute in Birmingham last autumn, by Mr. Bonehill, on the "Puddling of Molten Iron direct from the Blast Furnace," which were directed not to the suitability of the quality produced to its required use, but to its purity compared with bars made by a much more expensive process. Thus the main object of the paper, the economic production of a common iron, was largely overlooked. The sheet mills at A works consisted of three pairs of hard rolls turning out Russian sheets of a very high class. The output was small, but Mr. Thackray said he was told "They could easily treble the output if they did not put so much finish on it." That was to say, each mill was capable of rolling 33 tons per week if necessary, instead of 11 tons which they were then doing. The number of men employed at each pair of rolls was four, say, one roller and one catcher, each getting 5s. per day, two furnacemen at about the same wage, and one boy at the rack. Now this rack arrangement, which was usual in the new mills in Germany as well as in Belgium, was one by which the last end of the pack as it leaves the rolls was lifted by a lever under the control of the catcher or a boy, and appeared to be an excellent contrivance, as it hastened the operation and relieved the catcher of the most arduous part of his duty. The extra cost must be trifling. To sum up the position of the sheet manufacturers in Belgium, they could only conclude that fewer men were employed in the mills, whilst the wages from the pig to the finished sheets were much less than in England. To pass to the German sheet mills spoken of as at H and I works. It was first necessary to point out that the few sheet rolls at each works were but a very small portion of two very large steel making plants. He would take the two works together, as they were either rolling bars or waste materials from other departments of the works. What struck our sheet rolling experts in all these millls was the very high speed at which the rolls were running, say upwards of 120 revolutions per minute, or three times as fast as was usual in this district. Severe comments had been made on this statement as to speed, but he could not see any practical difficulty in the matter with the appliances described. These consisted first of an arrangement by which the screws were not touched by the roller or his breaker down, but were regulated by a boy controlling a central wheel moving both screws at the same time. In the second place, of the before-mentioned rack for helping the catcher to return the pack quickly. Then of distinct soft rolls for breaking down the bars; and, lastly, of three high hard rolls for finishing the sheets. These appliances together meant a large output and comparatively light labour. The German sheet rollers earned 7s. per day, the furnacemen the same, and the underhands from 4s. to 5s. Thus here again the total wages cost was below that of this country. He thought they must, on the evidence of the report, credit the works visited with machinery of a high order for rolling either iron or steel sheets. As to material rolled in Germany, little need be said, since the scrap and steel bars spoken of in the report were very much what they were with them. The only great advantage Germany possessed in this respect was in its large supplies of minette ores of most suitable composition for basic steel manufacture. He would now pass to labour, which, of necessity, occupied much space in the report. All the delegates, employers and employed alike, were evidently astonished at the splendid physical appearance, manly bearing, and quiet order of the workmen engaged in the mills and works. Now this problem of labour was one of great international interest, and from that point of view the first thing that struck one was the strange difference that existed in the relations between capital and labour in the three largest iron-producing countries in the world—Germany, England, and the United States. The races inhabiting those countries were sprung from a common stock, but the necessities of life, and the influence of environment, had modified the views of each in regard to this question in the most remarkable manner. In Germany, the old idea was still in force that those entrusted by Divine Right with authority must take a paternal interest in those they are called upon to rule, and cannot permit combinations against authority. In England, the land of freedom, where everyone was at liberty to combine against those they deemed opponents, individual claims were often mistaken for national ends, and labour fought its battles without regard to capital. In the United States they found vigorous action born of new surroundings, freed from prejudices, and stimulated by undeveloped opportunities. The result of these different conditions on the quantity and quality of what was produced was very great, and must be fully understood to appreciate the power each possesses in competing with the others. The German working-man was well trained in his youth, and disciplined in early manhood by two years' compulsory service in the army. On entering a trade he was compelled to keep a record of his occupations, without which it would be most difficult for him to obtain employment. He was not allowed to combine on the lines of their trades unions; these restrictions were heavy, and had raised a spirit of dissatisfaction amongst the labouring population of Germany, which curiously enough was not even hinted at in the report. On the other hand, as a set-off against the restrictions put on personal liberty, and to compensate for our poor law and free hospital system, employers, and especially those having works in isolated districts, had hospitals and special homes for their workmen, whilst the Government had established and enforced upon the whole population a system of accident funds and old age pensions, which bade fair to produce a spirit of contentment. It was impossible to ignore the fact that the social measures in force in Germany had aided manufacturers, and if the wages were low as compared with England and America, there was a more even distribution of the wage fund, provision during illness or accident, and a pension in old age without shame or disgrace. Their English labour population was trained under other conditions. It had inherited as its birthright freedom to act alone or in concert with others. It had no obligation to the State but what it chose to give voluntarily, and it was not amenable to order as all Germans were. In the matter of discipline our lads were not as well trained as they were in the old days of apprenticeships, and after leaving school they often wasted years in any sort of occupation that could be obtained until an opening offered in some definite trade to which, if they were sharp and steady, they became attached, probably joined some trades union, and considered themselves efficient workmen. This was not an ideal system, and did not tend to a spirit of regularity and thrift, or discipline of mind and body. For all that their English working population made as fine workmen as any in the world, but one grieved that they were not trained to appreciate discipline and self-restraint. In the United States the area was too large, and the interests of different districts too much opposed to permit of effective combinations of workmen in any one trade or occupation. In the ranks of all trades in that country were to be found some of the most enterprising of all our European nationalities. They lived in an atmosphere of push and hurry, and became, by force of their surroundings, worshippers of the almighty dollar. To succeed they must give of their best, or others equally good were ready to undertake the work. The employers recognised the fact that to obtain much they must give much, and in return for dollars the workman gave of his best. He had been induced to give this general sketch from the expressed opinion of the delegation that the lot of the workmen in the few works they saw—and he must ask them to remember they saw only the picked works of the best part of Germany—was better than that of the same class in England. Such a general assertion was not just or reasonable. Were their workmen willing to give up their freedom? He for one trusted not. The great lesson which labour and capital had to learn from the report was that the continental races by industry, regularity, discipline, and thrift were doing as good work as they at their best with greater happiness at less cost. A large German manufacturer said to him years ago, "Our masters and men are not opposed to changes, but welcome the introduction of new ideas." Now, unfortunately, he declared this country was daily losing trade which belonged to her, because she failed to throw away worn-out methods and processes. At the same time, she had driven trade to the Continent through continual struggles between labour and capital. Fortunately in the iron trade they had in their wages board an automatic arrangement for the rise and fall of wages as the price of iron rose and fell. By this means they had been for many years removed from the atmosphere of strikes. Still, here they were in great danger of suffering from the deadening influence of that form of trade unionism which maintained that a rule once made cannot be altered, whether it applied to the heats a puddler might work, whatever his furnace might be capable of, or to the schedule of the sheet mill wages which was spoken of as almost inspired, although those who framed it knew only too well that it was simply a compromise between the highest and the lowest wages paid in the different works at the time it was drawn up. What they all had to do was to recognise that their trade was not English but international, and that if they could not modify their ideas and habits as readily as the best of their competitors, whether in Europe or America, those competitors and not the English will eventually command the trade. He trusted that Institute of Managers would give earnest consideration to the following points:—(1) A more even distribution of the wage fund. (2) The adoption of the American principle of a minimum stint in rolling mills. (3) A shortening of hours rather than to a decrease in the number of hands. (4) To the inculcation of a spirit of thrift and consequent self-respect on the part of those who labour in the iron trade. If they undertook this task, he was sure the Wages Board would be only too glad to receive any suggestions that might appear to them desirable. Continuing, Mr. Punnett said he had left until the last the question of carriage, not because it was the least important, but because it affected not the iron trade only, but the whole community of the Midlands. For many years they had known how seriously this district suffered from excessive charges for the carriage of their heavy materials, coal and iron, to London and Liverpool, charges twice as great as for similar distances in Germany and Belgium. and three times as much as in the United States. Much energy was at first expended in endeavours to obtain reductions from the railway companies; but all efforts in that direction had long ceased, and there did not remain a shadow of a hope of any reduction from the railways. It was now indeed universally admitted that they must fall back upon their canals, as all other nations had been driven to do. France, Belgium, Germany, and the United States came to that conclusion long ago, and those countries were now honeycombed with splendid systems of large canals with small feeders. But although they had not as yet accomplished much in the Midlands, in that district the ground had been much cleared by the efforts of many public-spirited men. He was indebted to Sir A. Hickman, M.P., for a copy of the memorandum presented by him, as chairman of one of the committees which did splendid work, to the Wolverhampton Town Council. It was entitled, "Memorandum on the Improvement of the Canal Communication between Wolverhampton and London," and as he wished to make this matter very clear, having some proposals to offer thereon, he had taken the following facts from it. The committee estimated that the traffic between Wolverhampton and London was three times as great as between Wolverhampton and Liverpool, and seven times as great as between Wolverhampton and Bristol. They concluded, therefore, that it was most important first to enlarge the waterway to London. Another reason for undertaking this special part first was the fact that the canals between Birmingham and London were free from railway control, and were all now in the hands of the Grand Junction Canal Company. An engineer—Mr. Martin—was employed to survey and draw up estimates of cost of enlarging the existing canals, which they must please remember were still paying their way, although they had to charge a very high rate on account of the smallness of the boats they were compelled to use, so as to permit of the passage of boats or steamers of 140 tons burden. The total expenditure on this enlargement was estimated at £1,250,000, whilst the benefit to be derived therefrom was a reduction in carriage charges on iron from 12s. 6d. to 6s., and on coal from 6s. 9d. to 4s. per ton. This would be an admittedly splendid result. The scheme was put before the Town Councils of Birmingham and Wolverhampton, in the hope that conjointly they would be willing to guarantee a low rate of interest on the capital required, taking into account the enormous advantages the undertaking would be to the whole community. Unfortunately at that very time the Manchester Canal was being finished, and the municipalities appealed to declined to move in the matter. Sir Alfred, in a letter which he had sent him, and which he permitted him to quote, said, "Of course the Wolverhampton and London project is conceived on very different lines to the Manchester Ship Canal, and personally I have no doubt whatever that it could be made a commercial success, and at the same time confer enormous benefits upon South Staffordshire." It seemed to him the two schemes had no earthly relation to one another. One was an attempt to create an inland port for large ocean steamers at a point not fitted by position for the collection even of the varied goods which make large steam freights profitable. The other was the improvement of an existing system of canals for carrying natural products and the goods manufactured therefrom, and bringing back in return the requirements of an enormous population, to the greatest port in the world, which sends steamers laden with passengers and goods, collected not only from England, but from the whole of North Europe, to every region of the earth. In other words, the Manchester Canal could not succeed without drawing from many other districts profitable freights for ocean-going steamers, whilst Birmingham and Wolverhampton had all that was required to supply an abundant traffic for an enlarged canal without the creation of any new thing. Now it had been often stated that the iron trade in the Midlands should be removed to the coast, and it was therefore wise in urging even the comparatively small outlay suggested to see what good reasons there were for its remaining there permanently. In the first place, they had in South Staffordshire an abundant supply of most excellent coal for manufacturing purposes. In the second place, there were large beds of iron ore in Oxfordshire, Northamptonshire, and Lincolnshire, all within a small distance of the existing works of this district by good canals, and two of them would be served by the proposed enlarged one, and the cost would make the mouths water of many an owner of German blast furnaces. Then there were a vast number of trades dependent for their very existence on a good supply of cheap iron and steel. It was not indeed any exaggeration to say, that there were not many localities in Germany as well placed for the manufacture of iron, in most of its branches, as the neighbourhood of the coalfield of South Staffordshire. The point therefore remained, how could they set about this most necessary and great undertaking? The Municipal Councils in the area had declined to find the guarantee, and were not likely to do much for the carrying out of the work, although there were many members in each council whose assistance could be safely depended upon. Putting aside the Municipal, they had next the County and District Councils, which from their very constitution were much more likely to appreciate the grave necessity for this relief to the hard-pressed Midlands. He ventured to suggest that a complete scheme be prepared again and put before every Council likely to be affected both in the immediate neighbourhood and all along the route to London. Then every colliery proprietor and ironworks owner should be invited to bring the scheme before their associations, and lastly wages boards and trade unions should be asked to co-operate. If by such means as these the whole population were convinced that the work had to be done, and were, above all, willing to make sacrifices for that purpose, the congested money bags of the wealthy would be readily opened. Canals were not a popular investment with the public. They were, as a stockbroker once said to him, "too slow," and, as he added, the average investor prefers a gold mine, not requiring any proofs as to the existence even of gold in it. They must, therefore, look to their own initiatory efforts to be prepared to make sacrifices in the present that they might assure the future. To those good men and true who had already done much of the work, he would tell the following story, and he hoped they would forgive him its somewhat personal character. Many years ago when technical education and technical instruction were much sneered at, he was a member of the Council of the Birmingham Midland Institute and desirous of establishing classes for technical instruction. The opposition he met with somewhat disheartened him, when he fortunately met the late Dr. R. W. Dale, who said to him, "I am sorry to hear you are giving up that idea of yours. Let me give you my experience of the patience and time required to carry out even the simplest reforms. Many years ago I desired some alterations in the arrangements at Carr's-lane Chapel, but my ideas were not acceptable, and I had to wait. Well, not very long since those original proposals of mine were carried out—just ten years after I first made them."

The discussion upon the foregoing papers was opened by Mr. A. W. Hickman, eldest son of Sir Alfred Hickman, of the South Staffordshire Steel and Ingot Iron Company, and of the Spring Vale Furnaces, who briefly observed that he thought Mr. Punnett's suggestions with regard to the enlargement of the canals to London was well worth consideration, and he hoped they would all do their best to carry out the scheme.

Mr. Moses Millard—Isaac Jenks and Sons, Minerva Iron and Steel Works, Wolverhampton—said in his opinion Mr. Punnett was wrong in his figures respecting the wages in Germany and Belgium as compared with England, for he thought it would be found that the sheet mill wages in those two countries were as high, if not higher, than the wages paid for the like work here. It appeared to him desirable that we should look at our trade as international. He was afraid, however, that the discussion of that evening would all end in smoke, inasmuch as, in the majority of cases, the masters were satisfied with the present conditions of manufacture, and did not show a desire to move forward as their foreign competitors had. Sheets were rolled in Germany and Belgium from very thin bars. If they were rolled from thick bars, such as $1\frac{1}{8}$in. or $1\frac{1}{16}$in., like the English use, then the concussion would be so great, with the rolls running at so high a speed, that serious breakages to the machinery would occur. As to the military bearing of the workmen, he admitted that we ought in England to have a little more discipline than we got, but he hoped the time was a long way off before we should see the same sort of discipline as they had in Belgium and Germany, for he looked upon that as being just one remove from serfdom. He hoped Mr. Punnett was right when he declared that there was a good feeling existing between the masters and men on the Continent. He hoped the men really were perfectly satisfied with their position, but his own opinion was that there was a good deal of unrest among the working class in Germany. In fact, it was a seething mass of unrest and ferment, which would just now break out into open rebellion, and then the much-vaunted military system would be displayed to disadvantage. He was sorry to say the men's unions were very much averse to any changes that seemed to go against them, even though they were for the good of the trade generally. For ten or twelve years that Institute had been constantly advocating various improvements both in machinery and methods, and also in water carriage, but the manufacturers do not seem inclined to take up the matter, and therefore things practically remain where they were. A certain employer said to him not very many years ago when improvements dealing with machinery had been suggested, "Yes, that's all very well, Millard, it might effect a saving, but the machinery in its present condition will serve my time." He, Mr. Millard, was afraid that was the opinion of most of the masters in the English iron trade at the present time.

Mr. J. W. Hall, Lloyds' Steel Foundry Company, James Bridge, commenting upon the remarks of previous speakers, contended that masters were tired of laying down improved machinery, and then finding that because prices kept falling they were no better off. He recollected the time when a certain steel works was inaugurated, as he had a little to do with making some of the plant. Steel rails then were £22 a ton; he happened a little later on to see some of the rails rolled at £19 10s.; and the last rails were rolled at £4 10s. The works were stopped, and it was reported that the proprietors had lost half a million of money over them, though whether that was correct he could not say. Both masters and men could not help but recognise how greatly conditions had altered in recent years. Formerly our foreign competitors were handicapped in various ways. Take, for instance, the steel trade of Germany. At that time there was no basic process. All the ores for the steel process as then carried on had to be obtained in Cumberland, where our English works were situated, or from Spain, whence they could be brought cheaply into South Wales and the East Coast, and not at great expense into Sheffield itself. But that was all altered now. Phosphoric ores could now be used. The Germans were adopting the very best mills they could put down, and that they should be able to give us "a shaking up" was only to be expected. At present Germany was actually buying ores, and paying per unit upon the percentage of phosphorus, actually paying more for the phosphorus in order to get sufficient heat, which heat was formerly supplied by the silicon in the hematite process. In Belgium also they had splendid pig iron, and could produce steel at a price we could not touch. It seemed to be universally agreed that there was no possibility of our railway companies further reducing their rates to any material extent, for English lines were much more difficult both to make and maintain than continental ones. There was more tunnelling and embanking to be done in England, on account of the geographical nature of the country, and land was also dearer here. He thought we should have to rely on cheap water communication, and hoped the Midlands to London canal scheme referred to by the author would be again taken in hand. London was decidedly the best port to make for.

Mr. Le Neve Foster, Mr. George Wright, and Mr. Yeomans also contributed to the discussion, corroborating the author's opinions.

Mr. Chambers, of Messrs. Hill and Smith, galvanised iron manufacturers, Brierley Hill, also took part in the discussion, and went into various points, arguing that English masters would not feel foreign competition so severely if they would but spend capital in improving their plant.

The Chairman said that scarcely a word of praise had been meted out to the delegation for the work they had done. He had read the report, and the first thing that struck him was that the delegation did so much in so short a time. He found that there was a great deal in the report which specially commended itself to the British workman, more to the British works manager, and still more to the masters of this country. They had, it appeared to him, to dissociate from their minds entirely the old idea that the continental workmen worked for very low wages, lived in hovels, and had no home comforts. If they believed the report, they must come to the conclusion that most of their competitive workmen were well paid, not in wages, but in equivalents. They were also well housed and well educated, and they might depend upon it that it was owing a great deal to their education that they had the discipline which was made so much of in the report, and which was a very important factor in works. In this country they had no desire to see their workmen converted into automatons, but it was desirable that they should conform to the rules of the works better than they had done. Discipline was a thing almost unknown in the majority of their works.

The proceedings terminated with a vote of thanks to Mr. Punnett.

A PIECE-RATE SYSTEM.*

THE following is considered to be a step toward partial solution of the labour problem, by Fred. W. Taylor, Germantown, Philadelphia, Pa., member of the Society.

INTRODUCTION.

The ordinary piece-work system involves a permanent antagonism between employers and men, and a certainty of punishment for each workman who reaches a high rate of efficiency. The demoralising effect of this system is most serious. Under it, even the best workmen are forced continually to act the part of hypocrites, to hold their own in the struggle against the encroachments of their employers. The system introduced by the writer, however, is directly the opposite, both in theory and in its results. It makes each workman's interests the same as that of the employer, pays a premium for high efficiency, and soon convinces each man that it is for his permanent advantage to turn out each day the best quality and maximum quantity of work. The writer has endeavoured in the following pages to describe the system of management introduced by him in the works of the Midvale Steel Company, of Philadelphia, which has been employed by them during the past ten years with the most satisfactory results. The system consists of three principal elements:—(1) An elementary rate-fixing department. (2) The differential rate system of piece-work. (3) What he believes to be the best method of managing men who work by the day.

Elementary rate-fixing differs from other methods of making piece-work prices in that a careful study is made of the time required to do each of the many elementary operations into which the manufacturing of an establishment may be analysed or divided. These elementary operations are then classified, recorded, and indexed, and when a piece-work price is wanted for work, the job is first divided into its elementary operations, the time required to do each elementary operation is found from the records, and the total time for the job is summed up from these data. While this method seems complicated at the first glance, it is, in fact, far simpler and more effective than the old method of recording the time required to do whole jobs of work, and then, after looking over the records of similar jobs, guessing at the time required for any new piece of work. The differential rate system of piece-work consists briefly in offering two different rates for the same job; a high price per piece, in case the work is finished in the shortest possible time and in perfect condition, and a low price, if it takes a longer time to do the job, or if there are any imperfections in the work. The high rate should be such that the workman can earn more per day than is usually paid in similar establishments. This is directly the opposite of the ordinary plan of piece-work, in which the wages of the workman are reduced when they increase their productivity.

The system by which the writer proposes managing the men who are on day-work consists in paying men and not positions. Each man's wages, as far as possible, are fixed according to the skill and energy with which he performs his work, and not according to the position which he fills. Every endeavour is made to stimulate each man's personal ambition. This involves keeping systematic and careful records of the performance of each man, as to his punctuality, attendance, integrity, rapidity, skill, and accuracy, and a readjustment from time to time of the wages paid him, in accordance with this record. The advantages of this system of management are:—First: that the manufactures are produced cheaper under it, while at the same time the workmen earn higher wages than are usually paid. Second: since the rate-fixing is done from accurate knowledge instead of more or less by guess-work, the motive for holding back on work, or "soldiering," and endeavouring to deceive the employers as to the time required to do work, is entirely removed, and with it the greatest cause for hard feeling and war between the management and the men. Third: since the basis from which piece-work, as well as day-rates, are fixed is that of exact observation, instead of being founded upon accident or deception, as is too frequently the case under ordinary systems, the men are treated with greater uniformity and justice, and respond by doing more and better work. Fourth: it is for the common interest of both the management and the men to co-operate in every way, so as to turn out each day the maximum quantity and best quality of work. Fifth: The system is rapid, while other systems are slow, in attaining the maximum productivity of each machine and man; and when this maximum is once reached, it is automatically maintained by the differential rate. Sixth: it automatically selects and attracts the best men for each class of work, and it developes many first-class men who would otherwise remain slow or inaccurate, while at the same time it discourages and shifts out men who are incurably lazy or inferior. Finally: one of the chief advantages derived from the above effects of the system is, that it promotes a most friendly feeling between the men and their employers, and so renders labour unions and strikes unnecessary.

There has never been a strike under the differential rate system of piece-work, although it has been in operation for the past ten years in the steel business, which has been during this period more subject to strikes and labour troubles than almost any other industry. In describing the above system of management, the writer has been obliged to refer to other piece-work methods, and to indicate briefly what he believes to be their shortcomings.

(1) Capital demands fully twice the return for money placed in manufacturing enterprises that it does for real estate or transportation ventures. And this probably represents the difference in the risk between these classes of investments.

(2) Among the risks of a manufacturing business, by far the greatest is that of bad management; and of the three managing departments, the commercial, the financiering, and the productive, the latter, in most cases, receives the least attention from those that have invested their money in the business, and contains the greatest elements of risk. This risk arises not so much from the evident mismanagement, which plainly discloses itself through occasional strikes and similar troubles, as from the daily more insidious and fatal failure on the part of the superintendents to secure anything even approaching the maximum work from their men and machines.

(3) It is not unusual for the manager of a manufacturing business to go most minutely into every detail of the buying and selling and financiering, and arrange every element of these branches in the most systematic manner, and according to principles that have been carefully planned to ensure the business against almost any contingency which may arise, while the manufacturing is turned over to a superintendent or foreman, with little or no restrictions as to the principles and methods which he is to pursue, either in the management of his men or the care of the company's plant.

(4) Such managers belong distinctly to the old school of manufacturers; and among them are to be found, in spite of their lack of system, many of the best and most successful men of the country. They believe in men, not in methods, in the management of their shops; and what they would call system in the office and sales departments, would be called red tape by them in the factory. Through their keen insight and knowledge of character they are able to select and train good superintendents, who in turn secure good workmen; and frequently the business prospers under this system—or rather, lack of system—for a term of years.

(5) The modern manufacturer, however, seeks not only to secure the best superintendents and workmen, but to surround each department of his manufacture with the most carefully woven network of system and method, which should render the business, for a considerable period, at least, independent of the loss of any one man, and frequently of any combination of men.

(6) It is the lack of this system and method which, in the judgment of the writer, constitutes the greatest risk in manufacturing; placing, as it frequently does, the success of the business at the hazard of the health or whims of a few employés.

(7) Even after fully realising the importance of adopting the best possible system and methods of management for securing a proper return from employés and as an insurance against strikes and the carelessness and laziness of men, there are difficulties in the problem of selecting methods of management which shall be adequate to the purpose, and yet be free from red tape, and inexpensive.

(8) The literature on the subject is meagre, especially that which comes from men of practical experience and observation. And the problem is usually solved, after but little investigation, by the adoption of the system with which the managers are most familiar, or by taking a system which has worked well in similar lines of manufacture.

(9) Now, among the methods of management in common use there is certainly a great choice; and before describing the "differential rate" system it is desirable to briefly consider the more important of the other methods.

(10) The simplest of all systems is the "day-work" plan, in which the employés are divided into certain classes, and a standard rate of wages is paid to each class of men; the labourers all receiving one rate of pay, the machinists all another rate, and the engineers all another, &c. The men are paid according to the position which they fill, and not according to their individual character, energy, skill, and reliability.

(11) The effect of this system is distinctly demoralising and levelling; even the ambitious men soon conclude that since there is no profit to them in working hard, the best thing for them to do is to work just as little as they can and still keep their position. And under these conditions the invariable tendency is to drag them all down even below the level of the medium.

(12) The proper and legitimate answer to this herding of men together into classes, regardless of personal character and performance, is the formation of the labour union, and the strike,

---

either to increase the rate of pay and improve conditions of employment, or to resist the lowering of wages and other encroachments on the part of employers.

(13) The necessity for the labour union, however, disappears when men are paid, and not positions; that is, when the employers take pains to study the character and performance of each of their employés and pay them accordingly, when accurate records are kept of each man's attendance, punctuality, the amount and quality of work done by him, and his attitude towards his employers and fellow-workmen. As soon as the men recognise that they have free scope for the exercise of their proper ambition, that as they work harder and better their wages are from time to time increased, and that they are given a better class of work to do—when they recognise this, the best of them have no use for the labour union.

(14) Every manufacturer must from necessity employ a certain amount of day labour which cannot come under the piece-work system; and yet how few employers are willing to go to the trouble and expense of the slight organisation necessary to handle their men in this way! How few of them realise that, by the employment of an extra clerk and foreman, and a simple system of labour returns, to record the performance and readjust the wages of their men, so as to stimulate their personal ambition, the output of a gang of twenty or thirty men can be readily doubled in many cases, and at a comparatively slight increase of wages per capita!

(15) The clerk in the factory is the particular horror of the old-style manufacturer. He realises the expense each time that he looks at him, and fails to see any adequate return; yet by the plan here described the clerk becomes one of the most valuable agents of the company.

(16) If the plan of grading labour and recording each man's performance is so much superior to the old day-work method of handling men, why is it not all that is required? Because no foreman can watch and study all of his men all of the time, and because any system of laying out and apportioning work, and of returns and records, which is sufficiently elaborate to keep proper account of the performance of each workman, is more complicated than piece-work. It is evident that that system is the best which, in attaining the desired result, presents in the long run the course of least resistance.

(17) The inherent and most serious defect of even the best managed day-work lies in the fact that there is nothing about the system that is self-sustaining. When once the men are working at a rapid pace, there is nothing but the constant unremitting watchfulness and energy of the management to keep them there; while with every form of piece-work each new rate that is fixed ensures a given speed for another section of work, and to that extent relieves the foreman from worry.

(18) From the best type of day-work to ordinary piece-work the step is a short one. With good day-work the various operations of manufacturing should have been divided into small sections or jobs, in order to properly gauge the efficiency of the men; and the quickest time should have been recorded in which each operation has been performed. The change from paying by the hour to paying by the job is then readily accomplished.

(19) The theory upon which the ordinary system of piece-work operates to the benefit of the manufacturer is exceedingly simple. Each workman, with a definite price for each job before him, contrives a way of doing it in a shorter time, either by working harder or by improving his method; and he thus makes a larger profit. After the job has been repeated a number of times at the more rapid rate, the manufacturer thinks that he should also begin to share in the gain, and therefore reduces the price of the job to a figure at which the workman, although working harder, earns, perhaps, but little more than he originally did when on day-work.

(20) The actual working of the system, however, is far different. Even the most stupid man, after receiving two or three piece-work "cuts" as a reward for his having worked harder, resents this treatment and seeks a remedy for it in the future. Thus begins a war, generally an amicable war, but none the less a war, between the workmen and the management. The latter endeavours by every means to induce the workmen to increase the output, and the men gauge the rapidity with which they work, so as never to earn over a certain rate of wages, knowing that if they exceed this amount the piece-work price will surely be cut, sooner or later.

(21) But the war is by no means restricted to piece-work. Every intelligent workman realises the importance, to his own interest, of starting in on each new job as slowly as possible. There are few foremen or superintendents who have anything but a general idea as to how long it should take to do a piece of work that is new to them. Therefore, before fixing a piece-work price, they prefer to have the job done for the first time by the day. They watch the progress of the work as closely as their other duties will permit, and make up their minds how quickly it can be done. It becomes the workman's interest then to go just as slowly as possible, and still convince his foreman that he is working well.

(22) The extent to which, even in our largest and best-managed establishments, this plan of holding back on the work—"marking time," or "soldiering," as it is called—is carried on by the men, can scarcely be understood by one who has not worked among them. It is by no means uncommon for men to work at the rate of one-third, or even one-quarter, their maximum speed, and still preserve the appearance of working hard. And when a rate has once been fixed on such a false basis, it is easy for the men to nurse successfully "a soft snap" of this sort through a term of years, earning in the meanwhile just as much wages as they think they can without having the rate cut.

(23) Thus arises a system of hypocrisy and deceit on the part of the men which is thoroughly demoralising, and which has led many workmen to regard their employers as their natural enemies, to be opposed in whatever they want, believing that whatever is for the interest of the management must necessarily be to their detriment.

(24) The effect of this system of piece-work on the character of the men is in many cases so serious as to make it doubtful whether, on the whole, well-managed day-work is not preferable.

(25) There are several modifications of the ordinary method of piece-work which tend to lessen the evils of the system, but I know of none that can eradicate the fundamental causes for war, and enable the managers and the men to heartily co-operate in obtaining the maximum product from the establishment. It is the writer's opinion, however, that the differential rate system of piece-work, which will be described later, in most cases entirely harmonises the interests of both parties.

(26) One method of temporarily relieving the strain between workmen and employers consists in reducing the price paid for work, and at the same time guaranteeing the men against further reduction for a definite period. If this period be made sufficiently long the men are tempted to let themselves out and earn as much money as they can, thus "spoiling" their own job by another "cut" in rates when the period has expired.

(27) Perhaps the most successful modification of the ordinary system of piece-work is the "gain-sharing plan." This was invented by Mr. Henry R. Towne, in 1886, and has since been extensively and successfully applied by him in the Yale and Towne Manufacturing Company, at Stamford, Conn. It was admirably described in a paper which he read before this society in 1888. This system of paying men is, however, subject to the serious, and I think fatal, defect that it does not recognise the personal merit of each workman; the tendency being rather to herd men together and promote trades unionism, than to develope each man's individuality.

(*To be continued.*)

IRON AND STEEL INSTITUTE.

THE annual meeting will be held at the Institution of Civil Engineers, Great George-street, Westminster, on Thursday and Friday, May 7th and 8th, 1896, commencing each day at 10.30 a.m. The following programme of arrangements has just been issued:—

Thursday, May 7th.—9.30 a.m., meeting of Council at 25, Great George-street. 10.30 a.m., general meeting of members. The Council will present their report for the year 1895. The hon. treasurer, Mr. William Whitwell, will present the statement of account for 1895. Scrutineers will be appointed for the examination of the voting papers. The Bessemer Gold Medal for 1896 will be presented to Dr. Hermann Wedding, of Berlin. A selection of papers will be read and discussed. Seven p.m., annual dinner of the Institute, at the Freemasons' Tavern. Tickets, 10s. 6d. each, not including wine. Members may purchase tickets for friends.

Friday, May 8th.—10.30 a.m., general meeting of members at the Institution of Civil Engineers. A selection of papers will be read and discussed.

The following is a list of the papers that are expected to be read and discussed:—(1) "On the Rate of Diffusion of Carbon in Iron," by Professor W. C. Roberts-Austen, C.B., F.R.S., Member of Council.

(2) "On some Alloys with Iron Carbides," by J. S. de Benneville, Philadelphia.

(3) "On Mond Gas, as applied to Steelmaking," by John H. Darby, Brymbo.

(4) "On Hot-Blast Stoves," by B. J. Hall, Westminster.

(5) "On the Hardening of Steel," by H. M. Howe, Boston. Adjourned discussion.

(6) "On the Introduction of Standard Methods of Analysis," by the Baron Hanns Jüptner von Jonstorff, Neuberg, Austria.

(7) "On the Production of Metallic Bars of any Section by Extrusion," by Perry F. Nursey, London.

(8) "On Mr. Howe's Researches on the Hardening of Steel," by F. Osmond, Paris.

(9) "On the Treatment of Magnetic Iron Sand," by E. Metcalf Smith, New Zealand.

(10) "On the Making of the Iron Ores of Oxfordshire," b E. A. Walford, F.G.S., Banbury.

TRADE AND BUSINESS APPOINTMENTS.—For the convenience of their Lancashire and North of England customers, Messrs. Merryweather & Sons, London, have just opened a branch establishment at 39 & 40, Arcade Chambers, St. Mary's-gate, Manchester.—Messrs. G. Waller and Co. notify removal of their offices to 165, Queen Victoria-street, E.C.—Messrs. Rose, Downs, and Thompson, Limited, have opened offices at Dunster House, Mark-lane, London, E.C. Mr. Charles White, who has been with the firm in Hull for the last seven years, will represent them permanently in London.—Messrs. H. and S. Barker and Co., Mexborough, Rotherham, announce that they have appointed Mr. A. W. Harvey, of 110, Cannon-street, E.C., to be their sole London agent for the sale of their railway wheels, axles, buffers, and springs.—Messrs. Fleming and Ferguson, Limited, shipbuilders and engineers, Paisley, have received an order from the Queensland Government to build a powerful pump and bucket hopper dredger, and have also contracted with the Cork Harbour Commissioners to build a self-propelling side-ladder bucket dredger.

RAILWAY MATTERS.

WE regret to announce the death of Mr. John Jones, Secretary of the Taff Vale Railway for thirty years. He was long associated with Mr. Geo. Fisher, O. Fisher, J. Hurman, and Mr. Brewer, the leading minds of the Taff Vale Railway under the old *régime*.

A GANG of platelayers were at work about five o'clock on Tuesday evening in Sapperton Tunnel, on the Great Western Railway, four miles east of Stroud, when, in getting out of the way of a down train, they failed to notice the approach of an up train. The latter dashed into their midst, killing two on the spot and injuring another so terribly that he died on the way to the hospital.

IN the enumeration of train accidents in the report of the accidents on our lines last year it is shown that 26 consisted of collisions between passenger trains or portions of such. There were 46 collisions between passenger trains and goods or mineral trains, and 49 instances in which passenger trains or some of the vehicles left the rails. There were only 12 cases in which goods trains or parts of them were derailed. Thirty-nine trains ran through gates at level crossings, and 148 ran over cattle or other obstructions on the line. There were 188 failures of axles, 314 broken rails, and 454 failures of tires. Only three of the rails which broke were made of iron, the remainder being of steel. It is stated that the failures of rails and tires caused no personal injury; but this seems to ignore the fatal result of the broken rails at St. Neots in November last.

AT the annual general meeting of the northern section of the Société de l'Industrie Minerale, held at Douai, M. Baily gave an account of the progress achieved in underground haulage by electricity at the Marles Colliery, in No. 4 pit, of which the first experiment in underground haulage by electric locomotives was made in 1890. At first nothing but difficulty was encountered, but in 1891 everything worked satisfactorily, and after three years' practical experience it was decided to apply the system on a much larger scale to No. 5 pit. A 500-horse compound steam engine will drive four 80,000-watt dynamos, making 350 revolutions per minute, for actuating eleven locomotives in Nos. 3 and 5 pits. In the roads are laid rolled joists, weighing 8·75 kilos. per metre; and each locomotive, weighing 3·2 tons, is actuated by a Gramme-wound dynamo making 10,000 revolutions per minute, receiving the electric current at 500 volts, and giving out a useful work of fifteen horses. Each locomotive draws a set of thirty tubs, each holding half a ton of coal, and moving at a mean speed of 14 kiloms.—8½ miles—per hour.

THE first Government railway in Western Australia, from Geraldton to Northampton, was opened on the 26th July, 1879, but the progress of construction was slow, and on the 31st December, 1890, only 183 miles of Government railways were open for traffic; since then, however, great strides have been made—due almost entirely to the goldfields. On the 30th June, 1895, 573 miles were worked, and 382 miles either under construction or about to be constructed; in addition to this there are also 572 miles of private railways. The first railway line in South Australia—Goolwa to Port Elliot—was opened on 18th March, 1854; and the first line in Queensland on 31st July, 1865, from Ipswich to Grandchester. In Victoria the railways are under State control, although they were initiated by private enterprise. By March, 1853, three companies had been incorporated and secured extraordinary concessions in the shape of land and guaranteed interest. The Melbourne and Murray River Company was forced to sell to the Government in 1855, before any of their lines had been opened for traffic. The Geelong-Melbourne Company followed the same course in 1860, and only the Hobson's Bay Railway Company held its own for some years, but in 1878 sold its interests to the Government for the sum of £1,320,800.

THE annual report of the Japanese Imperial Railway Department for the year ending March, 1894, recently published, shows great progress made in less than a quarter of a century. The first railway constructed in Japan was the short line, eighteen miles long, between Tokyo and Yokohama, which was begun April, 1870, and completed September, 1872. At the date of the report there were 558 miles of Government railways and 138 miles of private railways in operation. For some years past the Government has practically ceased constructing railways, and during the year dealt with in the report only seven miles of special construction were added, while sixty-one miles of new private lines were opened during the same time. There were on March 31st, 1894, 995 miles of railway either under construction or for which surveys had been made and charters granted, a considerable part of which has since been completed. There were thirty-four applications during the year for permission to form companies for the construction and working of railways. Besides these, applications for extensions of existing lines were made by eleven railway companies. The whole of these forty-five projects come under application for provisional charters. The number of railway charters granted during the year amounted to eleven, and of provisional charters to five.

THE returns of accidents and casualties reported to the Board of Trade as having occurred upon the railways in the United Kingdom during the twelve months ended December 31st, 1895, show that in the lists of both killed and wounded there is a decrease since the record of last year. The total number of killed was 1024, a decrease of 91, and of injured 4021, a decrease of 99 on the year 1894. The numbers are classified as follows:—Passengers killed from accidents to trains, rolling stock, permanent way, &c., 5; injured, 399; by accidents from other causes—killed, 78; injured, 710. In 1894, 117 passengers were killed, and 1168 injured. These figures show a decrease of 34 passengers killed, and a decrease of 59 injured, on the preceding year. Turning to servants of railways or contractors, we find that 12 were killed, and 88 injured by accidents to trains, rolling stock, permanent way, &c., and 430 killed, and 2566 injured by accidents from other causes. Of persons passing over railways at level crossings, 65 were killed, and 33 injured; trespassers, including suicides, 381 killed, and 144 injured; other persons not included in the above classification, 53 killed, and 81 injured. If all the accidents occurring on railway premises, in addition to those caused by the movement of railway vehicles, be reckoned, it will be found that the total number of personal accidents reported to the Board of Trade during the year amounted to 1090 persons killed, and 9318 injured.

THE railways in the colonies of Victoria and Queensland belong exclusively to the State; in New South Wales there are 84 miles of private line, besides about 200 miles of "coal lines," owned by various collieries; in South Australia 16½ miles; and Western Australia possesses 572 miles of private lines. In New South Wales the first railways were projected as far back as 1846, and a few years afterwards a company—the Sydney Tram and Railway Company—was formed. The company undertook the construction of a line from Sydney to Parramatta, a distance of 14 miles, but as the capital became absorbed before the work was completed, the company was unable to carry on operations, and in the end the Government had to take over the line, which was finished on September 26th, 1855. A company also contemplated constructing a line from Newcastle to Maitland, but was unable to surmount the preliminary difficulties. There are in New South Wales two important public lines constructed and maintained by private companies:—(1) The railway between Deniliquin, in Riverina, and Moama, on the Murray, 45 miles in length. (2) The private line between Broken Hill and Cockburn, on the South Australian border—35 miles—connects with the South Australian lines, and is, owing to the large traffic done with the Broken Hill mines, a great financial success. In the Newcastle and Illawarra districts there are about 200 miles of private lines almost entirely used for the coal traffic.

NOTES AND MEMORANDA.

THE quantity of tallow produced in New South Wales during 1894 was 1,066,100 cwt., of which 847,236 cwt. were exported.

THE value of the gold converted into coin at the Sydney Mint during the period 1855—1894 was £76,072,000, of which £3,067,000 was coined in 1894.

THERE are in New South Wales eighty-three flour-mills, employing 696 hands, with an annual output of over 118,000 tons of flour or about 1400 tons on an average per mill.

IN 1840 there were 736 flour mills in Pennsylvania, with an annual capacity of 1,193,405 barrels. There were also 2554 grist mills. The capacity of the comparatively few mills reported by members of the Pennsylvania Millers' State Association at the present time is nearly 8,000,000 barrels a year.

MAGNESIUM paper, used for producing the magnesium light, is made in the following manner:—Powdered magnesium is placed between two sheets of impermeable paper which have been covered with starch paste, and they then adhere together. After drying, a sheet covered with potassium chlorate is pasted on each side, so that the powdered magnesium contained between the first sheets has a layer of potassium chlorate on each side. A further sheet pasted on serves as covering, and the whole, which forms a thick sheet, can be cut into strips. On lighting the end of a strip, the white dazzling magnesium light is obtained. According to the *Journal* of the Society of Chemical Industry, this paper is said to to be free from danger, and to keep well.

PROF. KAMERLINGH ONNES, starting from his theorem that Van der Waals's corresponding states are dynamically similar, inferred in a recent communication to the Amsterdam Academy of Sciences, that the cooling of the gas in Thomson and Joule's porous plug will, according to their experiments with hydrogen, 1862, become zero and turn into heating, with all gases, at sufficiently high temperatures. The author extended the theorem to thermo-dynamical similarity, and thus supplied the means to find the dimensions of an apparatus to liquefy hydrogen, if there is given one liquefying oxygen in a satisfactory manner. Linde's and Hampson's methods were considered from this point of view. The author also commented on his endeavours to get a small self-cooling motor, liquefying oxygen, to be used as a model for apparatus to liquefy hydrogen by doing work adiabatically after the manner of Solvay, and intended to form part of a series of theoretically perfect cooling apparatus. Finally the author pointed out the great importance of vacuum-jackets for low temperature work.

THE action of sulphuric acid in refining petroleum is very complicated, and its clarifying effect on the oil is influenced by the duration of exposure as well as by the strength of the acid. The deeper colour of oil that has been too long in contact with the acid would appear to be due, in part at least, to the decomposition of the acid tar at first formed and the re-solution of some of its asphaltic constituents by the oil. For this reason the practice prevailing in Baku, of using sludge acid over again in the process of preliminary acidification, is not recommended, since in its diluted condition this acid cannot possess such solvent properties as fresh acid. The other novel practice in Baku, of running into the acid agitator just before the end of the process about 1 per cent. of 30 deg. B. soda-lye and mixing the whole up for ten or fifteen minutes, causes, it is true, a rapid deposit of the sludge in the oil, but in some cases brings it down in big hard lumps difficult of removal from the agitator; it is, therefore, says the *Journal* of the Society of Chemical Industry, unavailable for Galician, Hungarian, and Roumanian oils.

AT a recent meeting of the Amsterdam Academy of Sciences Mr. D. van Gulik made a communication concerning an investigation made, under the direction of Prof. Haga, at Groningen, into the cause of the variation of resistance in microphonic contacts brought about by electric vibrations. In investigating the cause of the diminution of resistance through electric vibrations generated in bad microphonic contacts, it has been ascertained that the ends of a current-chain, when brought very close together, attract each other if the wires are exposed to Hertz's waves. The arrangements being made with proper care, the movable ends were seen under a microscope to touch each other as soon as electric vibrations were generated near them. The original air-gap must not be larger than four microns, and a contact arisen in this way offered a resistance of $\frac{1}{2}\,\Omega$ to the current. The removal of the element from the chain had no influence upon the phenomenon. When the air-gap was a few microns too large, then small sparks resulted on the wires being acted upon by the above-mentioned waves.

AMONGST the experiments on Röntgen x rays made during the past month by Italian physicists, several contributions may be cited which either tend to confirm the results established by other workers, or to establish new results. Signor A. Roiti describes (*Atti R. Acad. Lincei*) a series of experiments now in progress bearing on the question as to where these rays emanate. The principal conclusions arrived at are:—(1) That fluorescence does not necessarily accompany the emission of x rays; (2) that the rays are only emitted when kathodic rays impinge on certain substances, notably glass, aluminium, mica, platinum, and porcelain. Signor Roiti establishes some interesting results relating to the leakage of electricity which takes place when x rays fall on a charged body. When the body in question is placed in a vessel from which air is exhausted, this leakage effect is found to diminish rapidly after the pressure falls below a certain limit, showing, *Nature* says, that the leakage effect depends on the presence of molecules, by which electricity is conducted from the charged body to the containing vessel.

THE United States Consul in Liége describes, in a recent report, the manufacture of, and trade in, damascus gun barrels, wholly hand-made, in the valley of the Vesdre, in Liége province. These barrels are for sporting guns, and the industry is many years old, the workmen in the villages in the valley being almost all gun-barrel makers, and the trade descending from father to son. The best barrels are a combination of the best primary substances, welded and forged by the *martelage à froid* process; the steel comes from Westphalia, the iron is manufactured at Couvin, in Belgium, the coal, which is specially suited for the work, from the Hervé highlands in Belgium, while the motive power of the factories is obtained from the river Vesdre. Medium quality barrels are made of coke, iron, and steel, while the superior quality, which are produced in the Vesdre valley, are made of charcoal, iron and steel. An ingenious "marriage" of these metals gives a composition which, when manufactured, guarantees the required solidity and resistance. The improvement in these damascus barrels dates from the introduction of percussion caps in place of the old flint lock. Formerly iron barrels alone were produced; now, to manufacture the curled damascus, the ingot is composed of thirty sheets of iron and steel, each having a thickness of four millimetres, which are enveloped in a sheet-iron box, placed in an oven, and welded together at the lowest possible temperature. Each barrel receives 150 welding beats while being forged, and if a single one of these is unsuccessful, the barrel may be a failure, either by alteration of the damascened work, or an imperfection in the welding. The annual production of damascus barrels in the Vesdre valley is about 300,000 pairs, of the value of about three and a-half million francs. Of this the wages alone amount to about two million francs. The principal markets are Great Britain and the United States. About half the barrels made in the Vesdre valley are sold to manufacturers of arms in Liége to be mounted.

MISCELLANEA.

THE Lord President of the Council has appointed Professor J. Perry, D.Sc., F.R.S., to the vacant chair of Mechanics and Mathematics at the Royal College of Science, South Kensington.

THE Bombay Corporation has rejected a motion in favour of the purchase of one or two horseless carriages by way of trial, on the ground that the invention had not yet passed through the experimental stage.

AT a meeting of the Court of the Coach and Coach-harness Makers' Company, held in London, on the 9th inst., under the presidency of the Lord Mayor, who is Master of the Company, the honorary freedom of the ancient company was presented to Mr. John Philipson, jun., of the firm of Atkinson and Philipson, carriage and harness manufacturers, Newcastle, in recognition of his work during the past twelve years in the promotion of technical education.

A WELSH contemporary has published an original letter from the late William Crawshay, the "Iron King," sent to the *Times* some fifty years ago when the Bank of England held possession of Cwmavon Works on account of a large overdraft. The Bank, by one of its agents, carried on the works for several years, and Mr. Crawshay's indignation was great because the Bank undersold him in iron bars. The ironmaster tersely commented upon the injustice done by the Bank in bringing the great influence of its capital, which represented public money, to crush out private enterprise.

THE old Foudroyant, after many adventures, says the *Army and Navy Gazette*, is shortly to be placed on exhibition in the Thames. She is being restored in every respect to the condition in which she was at the time when Nelson's flag flew from her masthead. The guns are actually those in use when the ship was in commission, having been purchased from the Admiralty for the purpose. No trouble or expense, indeed, appears to have been spared to make her a unique specimen of the "wooden walls" of England. Masts, sails, fittings above and 'tween decks, and even the old character will be carried out so far as the crew is concerned by dressing the men in the costume of the period. The Foudroyant will also visit the Naval Exhibition at Kiel, and it is intended during the summer to show her at all the principal ports in the United Kingdom. If a success, as is pretty certain to be the case in this country, the Foudroyant will eventually visit the Colonies and the United States.

IN the coroner's inquiry into the result of an explosion at the Huddersfield Gasworks on Saturday, the evidence showed that on Saturday morning two men were working at the oxy-oil retorts, when an explosion took place, and both men were injured, one fatally. Mr. W. R. Herring, manager of the gasworks, said that from investigation he found that there had apparently been a defect of the nature of a porous blister in the cast iron work of one of the retorts. This defect would have a tendency to draw in the hot air from the brick setting in which it was fixed, and the mixture of the hot air and the oil gas had not only produced an explosive substance, but the hot air had been sufficient to cause ignition. The retorts were regularly examined, and on Wednesday all the retorts were found to be, it was thought, in a perfect condition. The jury returned a verdict of "Accidental death," expressing the opinion that neither the manager nor any of his staff were to blame for the occurrence.

DURING the last few weeks Lord Masham has been making extensive additions to his Ackton Hall Colliery, near Pontefract, which up to a few months ago only consisted of the Warren House seam. Some little time ago digging was commenced at the Haigh Moor seam, where some 150 to 200 extra hands have been employed, and when the shaft is opened out it is expected that another 250 or 300 men will be needed. At the start considerable difficulties were met with in the sinking. His lordship, however, had made up his mind that coal was to be found of a good thickness, and after working away for many weeks, and striking out in four different directions, the seam was struck at a depth of 620 yards, and found to be a thickness of 3ft. 10in. The depth of the newly-opened Haigh Moor is 400 yards, and the wheels of the pulley at the shaft head are 17ft. in diameter. Fifty new coke ovens have been erected, as well as a large slack washer, and from these ovens the gas travels into four large boilers, which works the machinery of the establishment. The whole of the colliery above ground is lighted by electricity, and for a hundred yards into the actual workings besides.

THE proposed or required new water supply for Cochin seems to be beset with difficulties. According to a contemporary several suggestions were put forward, viz.:—(1) The supply by pipes across the backwater from the mainland; (2) from the Periyar at Alwaye by pipes and pumping; (3) from Alwaye by water-in-bulk steamers; (4) by condensation; and (5) by boring. The first four suggestions had to be given up, as the cost of any one of them was found to be prohibitive, and now the trial boring, which has been in progress for some time, has had to be abandoned, as the Government has, owing to the opinion given by the Government Geologist that rock would not be reached for probably many thousand feet, refused to proceed further with it. The boring had reached a depth of 325ft., and on it a sum of Rs. 13,000 had been expended, inclusive of the cost of the apparatus. To continue it to a depth of 400ft. would involve the expenditure of an additional Rs. 5000, and to proceed further fresh plant would be necessary. The Municipal Council has been given the option of continuing it, the apparatus being placed at its disposal; but want of funds will scarcely admit of its doing this, and it seems as if the question of a water supply for Cochin must be indefinitely postponed.

IN his concluding lecture on "Light" at the Royal Institution on Saturday, the 11th inst., Lord Rayleigh deemed it meet to say a few words on the mysterious "Röntgen rays," although not without some scruples, since he thinks it has not yet been shown that the x rays are strictly "light," or even vibrations. The mere fact of photographing by invisible rays was of course no new thing at all; but Röntgen rays were not ordinary light waves. It might be doubted whether they were rays at all. Röntgen called them "strahlen," but "strahl" in German signified a jet or stream as well as a ray—a jet, it might be, of electrified particles. And some held that these rays really were electrified particles, running, of course, at an enormously high speed, and so far as the idea was confined to what was happening inside the vacuum tube, there were no particular difficulties in the way. But when you got outside the vacuum tube this theory was not so easy. It required rather a stretch to say the particles could penetrate through the glass. However, no one, as far as he understood, believed that the particles went right through. One idea was that they might bombard one side and cause corresponding particles to be shot or torn off the other side, just as happened when billiard balls were put in a row. One end ball being struck, the opposite end ball flew off. It was, of course, not very easy to understand how such a thing could happen as was supposed by this theory. Still, as they had to deal with a phenomenon so new and strange as this, the theory must not be excluded. On the other hand, suppose we imagined these rays to be vibrations of the ether. Then came the question, were they transverse vibrations—oscillating across the path in which they were travelling, like ordinary light waves—or were they longitudinal vibrations, a series of alternating compressions and rarefactions travelling in the direction of propagation, as was the case with sound? To answer this question there was at present little evidence one way or the other. However, although we could not decide at present whether they were longitudinal or transverse vibrations, we could not doubt but that they were of extremely short wave-length, otherwise they could never throw such good shadows. If they were transverse vibrations they must certainly be very much shorter than anything within our knowledge in the ordinary spectrum.

MILLING PLANING MACHINE

MESSRS. KENDALL AND GENT, MANCHESTER, ENGINEERS

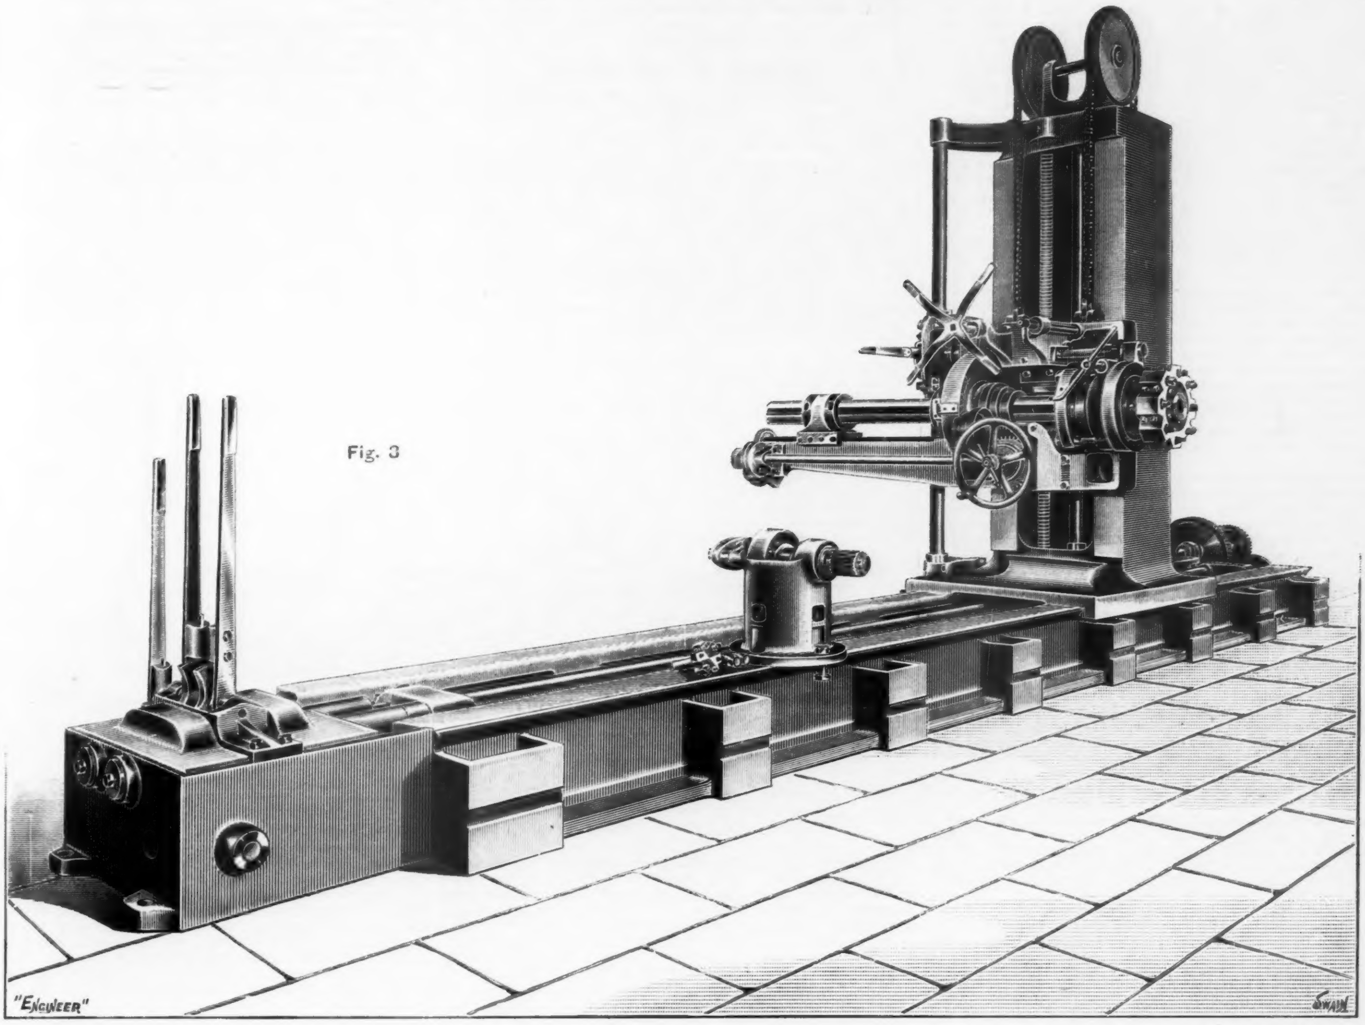

Fig. 3

"ENGINEER"

SWAIN

THE DEVELOPMENT OF THE MILLING MACHINE FOR HEAVY ENGINEERING WORK.

MR. SAMUEL DIXON, M.I.M.E., read before the members of the Manchester Association of Engineers, at their last ordinary meeting, a paper, in which he dealt with the development of milling during recent years for all classes of heavy engineering work, and pointed out the broad lines on which further progress in the same direction was still being made. One of the hindrances to the development of milling, he said, had been the existence of many surfaces which were originally designed for machining by a single tool, and on which a series of rotary cutters could not be employed. The chief aim in most modern designed milling machines had been to arrange the cutters to work on practically any surface that could be presented. Surfaces which were formerly finished on shaping machines were now almost invariably finished on horizontal milling machines with the ordinary spiral cutter where simple flat surfaces were concerned, or with gang cutters where several surfaces could be finished at one cut, as in the caps of pedestals and similar objects. In such work there was an enormous saving, for not only was a plain surface finished more quickly by milling than by shaping, but where several surfaces had to come together, or were required to be uniform in thickness or width, this uniformity could be ensured with the greatest certainty, whereas by the old process of shaping, the setting of the tool to every surface, and again to every object, introduced such a number of small errors and variations amongst the objects machined that the liberal use of the file and consequent expense was unavoidable. They might take a very simple illustration in such objects as screwing machine dies, which were plain bars of cast steel, machined all over, but which required to be uniform in thickness and in breadth. By the older process of shaping or planing, the cost of machining alone was quite double, if not treble that of milling, but even after machining a great difference came in, for slight deviations were always to be found among the dies shaped, and these had to be rectified by filing. By milling, however, these could be produced perfectly uniform, both in thickness and breadth, so that in such simple objects as keys for fly-wheels, pulleys, &c., uniformity could be attained with the greatest ease. Again, as to the quality of surface, there could be no question that the finish of a surface from milling was far superior in most objects to that of shaping, and was in fact superior to what could be produced even by the shaping machine and file together. Milled surfaces might therefore be regarded as surfaces which were so perfectly finished that they might in many cases be left from the machine. In addition to those plain surfaces which could be best milled with the plain spiral cutter, came a large number, in fact, the largest number, which could be done by face cutters. These face cutters, for comparatively small objects, were often made solid, but when made with inserted teeth, could be of practically any size.

It was this form of cutter which lent itself so admirably to almost every class of work, and which was doing so much for the development of milling. Another advantage of this cutter with inserted teeth was its comparative cheapness. The weight of steel used in any one cutter was also so small and of such a simple section that any ordinary workman could make, harden, and insert it; and seeing that so small a quantity was required in such a simple form, a steel of the highest quality could be employed, giving the same advantages in milling as was derived from the use of such steel in tool-holders for turning, planing, slotting, &c. There was one erroneous idea to be found occasionally amongst engineers as regards milling, and that was the supposition that it was not suitable for general miscellaneous surfaces, and was only of advantage where a number of objects were to be made exactly alike. This idea, he believed, arose from a recollection of the field in which milling first made its mark, *i.e.*, among small objects for sewing machines, knitting machines, small arms, &c. For such work the machines were very special, and had an extremely limited capacity, so much so that objects with a slight variation in form could not be dealt with by them. To-day this condition of things was entirely altered, for whilst there must ever remain a large number of machines specially intended for certain work, there were also machines having a perfectly universal character, ready for machining any surface upon which a little common sense had been expended in the design. It was, therefore, necessary to point out that the common spiral cutter and the face milling cutter, with either solid or inserted teeth, were together capable of machining almost any surface whatever. The only thing required was a machine so constructed as to be able to quickly present one or other of the cutters to the surface requiring machining, and at the same time to be able to support these cutters in such a manner as to get out the maximum amount of work.

With regard to work formerly done upon slotting machines, the gain in the adoption of milling was perhaps the greatest in the whole range of engineering practice. For the operations of key-grooving, and the machining of few extremely odd—often badly designed—surfaces, the slotting machine would perhaps always be necessary, but as a machine for producing finished surfaces in the wider sense, its use might be regarded as becoming rapidly obsolete. Not only was the work done more quickly on the milling machine, but it was, when finished, infinitely superior to that from the slotting machine, so that the saving of fitters' time formerly expended on adjusting and draw-filing was very great; in fact, the work of the fitter would, in the near future, be almost entirely confined to setting out work, and assembling the parts, after they had been finished on the machine. This, undoubtedly, was what should be the case, for fitters were simply men who, in the past, had been almost entirely occupied in correcting, by hand labour, the imperfections left in the work by the machines. Whether they would ever arrive at the state of perfection when hand work could be abolished in the production of all ordinary surfaces it was impossible to foretell, but with the introduction of milling it was tending very rapidly in that direction, and the ideal might now very fairly be regarded as within measurable distances.

Of all the tools in an engineer's shop, the vertical milling machine of the slotting machine type was perhaps the best, and as showing what he referred to, he had selected the one shown in the illustration Fig. 1 as a type of this class of machine. From the photograph it would be seen that whilst the cutter was firmly supported both above and below, it was driven by a strong spindle and spur-gearing. The circular table was provided with all adjustments and self-acting feeds, so that work could be rapidly mounted and brought to the cutter, much in the same way as in slotting machines. An interesting point about the driving was that spur-wheels only were employed, which could be entirely suppressed, and the belt alone used with light cuts, or for brass work. Where bevel gears were used for driving, it should be noted that these could never be suppressed. The spindle of the machine selected as a type was 5in. diameter in the body, and much larger in the front bearing, and being carried in conical bearings, formed an efficient driver to the mandril, without torsion and consequent vibration. A special feature was that the feed motions were entirely independent of the driving of the spindle, so that the speed of the spindle could be varied to suit the different diameters of the cutters without varying the rate of traverse; hence the amount of metal cut away by any individual tooth remained the same, whatever might be the diameter of the cutter. It would be noticed that the feed motion was positive, and not dependent on any frictional device after the strap, so that once the rate of feed, as given on the index attached to the machine, was decided, a uniform traverse could be relied upon, which was of great importance where a smooth uniform surface was required, for should the feed slip so that an additional number of revolutions of the cutter was taken on any one spot, a line or mark was certainly left upon the work.

Circular milling machines were, before all others, the type for use where all such objects as cranks, levers, &c., with circular ends had to be machined; but there was a wide field open for completely milling circular objects more economically than turning, even carrying the idea out as far as milling the edges and faces of pulleys and similar objects at the same time. The profile milling machine also lent itself well to profiling, or the milling of objects of irregular forms such as cams, burrs, &c. For this purpose the table was left free to slide longitudinally, so that a template of the same shape placed under the work determined the advance or withdrawal of the work as it passed before the cutter during the action of the transverse feed. It was of great importance when taking heavy cuts to have a bearing for the lower end of the mandril; yet it was surprising how much could be done on such a machine without any support. In fact, he had seen cutters being effectually used even 9in. long, and not more than 1¼in. diameter, without any support whatever. For general engineers the question of profile milling was only of secondary interest, seeing that good designers almost invariably succeeded in working out all their forms as combinations of straight lines and circles, so that fancy ogees and similar forms of a costly character were practically abandoned. This type of machine, which he felt tempted to name the slotto-milling machine, was also capable of doing an immense amount of work with face milling cutters, quite apart from its general work as an edge miller. Such work was formerly done on shaping machines, so that by using face as well as spiral cutters, objects could be milled on the top and all four sides at one setting. This was a point of much importance and often overlooked by engineers, who usually regarded its function as one of edge milling only.

A very interesting group of machines was comprised in those designed for doing work formerly done on planing machines, which, from their similarity in outlines and function, were now known as plano-milling machines. These were usually of the horizontal type or of a combined vertical and horizontal type. It was well known amongst engineers that quite one-third of a man's time, and also that of the producing capacity of many valuable machines, was lost in the setting of work, and this was unavoidable in planing machines, as nothing could be set on the table while in motion, and the difficulty could only be mitigated by the man having two machines, so that one was often working whilst the other was stopped for setting. It was at this point where a great advantage in milling came in, for the movement of the table was so slow that by having the machine sufficiently long, a second object could often be set ready while the other was being machined. The man and the machine could therefore be continuously occupied, so that a saving of about one-third the producing capacity of the machine could often be effected from this circumstance alone, quite apart from the gain arising from the use of a series of cutting edges as compared with that of a single point. For the milling of many objects formerly done on the chuck lathe, horizontal turning mill, &c., circular milling machines presented many advantages, and the illustration Fig. 2 might be taken as a type, though as shown it represented a special form adapted for milling round the flanges of cylinders, valve chests, &c., and was provided also with a radial drilling arm on the cross slide for drilling and tapping the stud holes when so set for milling. The machine shown admitted objects up to 7ft. 6in. diameter, and up to 8ft. 6in. high. When milling at such a height from the table it would be readily seen that provision had to be made for resisting strains of a totally different kind to those met with in planing machines, so that to ensure perfect rigidity the uprights for carrying the cross-slide were provided with transverse wings, and not merely the common form of upright usually found in planing machines. For the rapid adjustment of the work to the tool, and also the raising and lowering of the cross-slide, as well as the traversing of the saddles on the cross-slide, quick power motions were provided, in addition to the series of graduated speeds for feeding up the work when milling.

The necessity for milling machines for large fixed objects had sprung up just as did that for wall or side-planing machines In one important feature, however, they differed, for, seeing that powerful machines with strong spindles, having longitudinal, vertical, and transverse adjustments, were necessary for milling, it required but a slight addition to make the same machines into perfect boring, drilling, tapping, and studding machines. This combination had many advantages, for when an object was once set all the surfaces in most cases could be milled over, and the holes bored, drilled, or tapped, as the case might be. The economy arising therefrom was very great in heavy work, where operations were comparatively short when once set, and also where the cost of handling and setting in different machines was often very great. This was only another illustration of the tendency of all good machine designs to eliminate as far as possible the great cost of setting work accurately on machines. The machine shown in the illustration Fig. 3 was typical of this class, made in several sizes, the largest covering surfaces up to 30ft. long and 10ft. high, and not only was it suitable for milling over these surfaces, but also for boring. This machine might be taken as a type of these large boring and milling machines, the smaller sizes having spindles 4in. and the larger 6in. diameter. In addition to the large milling head, which could be used on the horizontal spindle, an extremely useful milling or boring head with a transverse spindle could be attached. It would be noted that this was mounted on a circular base, so that this spindle could be used vertically, horizontally, or set round to any angle, as in the universal plano-milling machine. It would not be of advantage to describe all the details of the various motions which it was necessary that such machines should be provided with, but as they had grown beyond the range of simple adjustment, they were now furnished with rapid-power adjustments in every direction, and well within the range of the workman and under such perfect control that only very slight adjustments for sizing and fine setting were ever required by hand.

Returning once more to the general question of milling, it would, he thought, be conceded, after comparing the capacities of the machines he had selected as types, that the whole range of engineering work was now well covered; not that every cranky surface which an inexperienced draughtsman had designed could be milled, but there was no reason why almost all surfaces should not be brought within the range of the milling machine, especially if, in designing, the few simple requirements of milling were kept in mind. At this point he might say that machine tool makers themselves had had, perhaps, more difficulties to contend with than other branches of engineering, but these difficulties were disappearing, and would very soon cease to exist. In treating thus fully the broad features of milling, he would not be understood to imply that planing machines would be put out of use in engineering shops, but, considering the advantages of milling, it behoved engineers to consider more carefully whether, in the classification of their work for economical production, a very much greater share should not be allotted to the milling machine. His object in preparing the paper had been not so much to present the novel features of any particular type of milling machine, but to emphasise what he considered two important advantages that would arise from a more extended use of milling machines, viz., increased economy of production, and greater accuracy or higher quality of the work produced. The former of these was a point which appealed to engineers of every class, and he rejoiced to think that the latter, increased accuracy of production, was a matter which was daily becoming more appreciated by engineers throughout the world.

A discussion followed the reading of the paper.

Mr. Hans Renold said he would have liked to hear more about the construction of the cutters used in milling machines, as this was, to his mind, a far more important question than that of the machines themselves. They might do good work with a good cutter and a badly designed machine, but they could not do good work with a bad cutter, however good the machine itself might be. With regard to driving the cutter, he did not believe in the cone-bearing adopted by the author; a parallel bearing was the best. Milling would, no doubt, in the future become a general operation in engineering works.

Mr. Saxon remarked that the question arose as to whether our existing general tools had been developed and improved to the extent that was possible. He thought great improvement was possible in the direction of utilising the return strokes in planing and slotting machines. Then he would like to know whether the operation of milling had got to such a point beyond the experimental stage that where they had only a limited number of ordinary machines, it would be advisable to entirely replace them with milling machines, or would it be better to adopt the system slowly, and gradually educate their men in the methods of milling, by first obtaining one machine and then steadily increasing the number as they became more familiar with the system. Then there was the matter of the cost of the milling machines, as compared with slotting or planing machines of the same sizes; the author had not dealt with that point. He did not think the ordinary tools would ever be dispensed with. In cases of breakdown work, for instance, they would always be necessary.

Mr. Daniels asked whether the author would recommend special tools for special work, or the universal tool, as, for example, in locomotive work.

Mr. Alfred Muir said Mr. Adams, of the Great Eastern Railway, was the first man to use milling machines for locomotive work. Mr. Webb, of Crewe, afterwards adopted them. There was no doubt as to the general usefulness of milling machines, and the larger the surface to be operated upon the more advantage they got from their use.

Mr. Webb asked whether milling could be recommended for slotting large cranks for mill engines.

Mr. Blastow said that, as far as he knew, Mr. Bodmer, of Chorlton-street, Oxford-road, Manchester, was the first maker of a milling machine, as he had made one in 1824. Milling machines had their place in an engineer's shop, and so had slotting and planing machines, but they must get the planing machine to cut without any loss of time if it was to hold its own. He believed that special machines, and not universal ones, were the most satisfactory machines for a large engineering shop, and with that condition they would hold their own, but would not displace the other tools.

The Chairman spoke very strongly against the common practice of insisting upon makers constructing a specially shaped tool for them for every small operation, instead of being satisfied with the standard pattern. This was often done when the question was simply one of chucks, and not of the general design of the machine itself. He thought circular milling should be more widely adopted in some directions than it was. There was no doubt the cardinal feature of a good milling machine was the cutters, and the grinding of these was a very important operation.

Mr. Blastow moved, and Mr. Saxon seconded, a vote of thanks to the author, which was carried with acclamation.

Mr. Dixon, in responding, said with regard to milling machines for heavy engineering work, they could not be made by the gross, and had to be specially constructed for the firm for whom they were intended. The remarks of Mr. Nasmith might apply to small machines, but not so decidedly to those with which he had been dealing. He did not agree with Mr. Renolds' remarks as to driving, as a solid drive was far preferable to a frictional drive such as was mentioned by that gentleman. He thought that milling machines should be adopted slowly at first in engineering shops where the ordinary tools were in use, or else the men would never become familiar with their working. Of course milling machines were more costly than ordinary tools, but this was owing to the better finish, mechanism, &c., required. With regard to breakdowns, Mr. Saxon was mistaken in thinking milling was not applicable. With the ordinary spiral cutter and face cutter, they could practically cover any surface. As to using special machines for special work, these were, no doubt, the best for locomotive work, and there was a large number of machines of different classes to choose from, but he had been dealing rather with general engineering work, and for this "universal" machines were often very useful. For the heavy cranks mentioned by Mr. Webb, the ordinary slotters were the best machines to use, though the cranks might be finished with a milling machine.

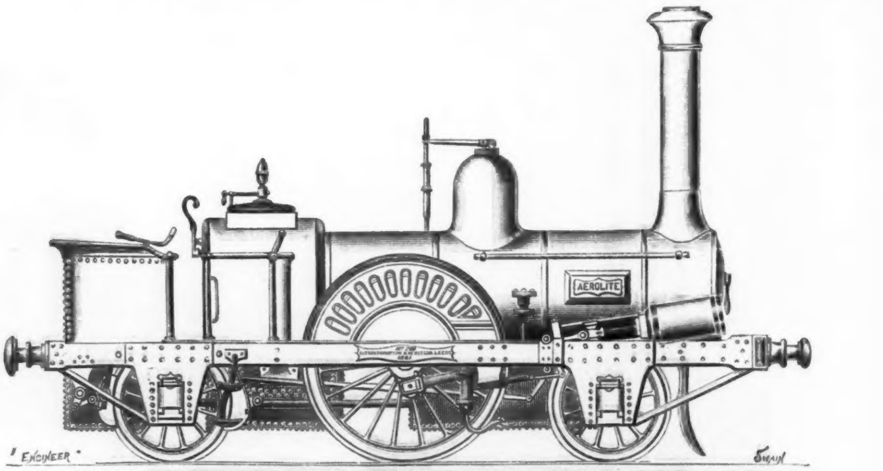
LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

THE LINKS IN THE HISTORY OF THE LOCOMOTIVE.

Sir,—I am enclosing print of an old single wheel tank engine which will, no doubt, be interesting to many of your readers, The engine in question was built in 1851 by Messrs. Kitsont Thompson, and Hewitson, of Leeds, and exhibited at the great exhibition in the same year.

The dimensions are as follows:—Cylinder, 11in. diameter by 22in. stroke; driving wheels, 6ft. diameter; leading and trailing wheels, 3ft. 6in. diameter. The engine is described as being "constructed to run light express trains, will run without tender, having two water tanks beneath the boiler and foot-plate to carry 500 gallons of water, and sufficient coke space upon the foot-plate to run for a journey of fifty miles."



TANK ENGINE, LEEDS NORTHERN RAILWAY, 1851

The engine afterwards ran for some years on the Leeds Northern Railway. W. J. Barker.

Woodsley View, Leeds, April 6th.

THE LIQUEFACTION OF GASES.

Sir,—I am sorry that your correspondent, "Cryos," does not find my theory of the action of Dr. Hampson's apparatus quite convincing. Incidentally I may point out that it is not a theory, but a simple statement of facts. If "Cryos" had read my letter with more care, I do not think he could have avoided conviction.

His difficulty is in accounting for the heat energy expended by the compressing engine. "If," he says, "no heat can escape from the apparatus, it must become red hot." I have not my copy of The Engineer with my letter by me, but so far as I remember I did not say that no heat escaped from the apparatus. I did say that none of the original heat in the air or oxygen could escape, or did escape, which is a very different thing.

Let us suppose that 100 lb. of air at atmospheric pressure, occupying at 62 deg. a space of, in round numbers, 1300 cubic feet, is isothermally compressed until it occupies 13 cubic feet, and has a pressure of 1500 lb. on the square inch. Its temperature is still 62 deg., because it has been cooled during the process of compression. Its intrinsic energy before compression was $100 \times 62 \times {\cdot}23 = 1426$ thermal units. Its energy after compression will be precisely the same, because the energy in a gas is a function of its temperature, and of nothing else. Now, in Dr. Hampson's apparatus we have, say, 100 lb. of air compressed to 3000 lb. on the square inch, or to any other pressure necessary. The energy in it is just what it was before compression. It has lost nothing; but it may have gained a little, because the heat due to compression has been abstracted from it in the surface condenser or cooler. Now the lowest temperature that can be got in the cooler, without the aid of ice or some refrigerating agent, is that of the surroundings, or 62 deg. by hypothesis; and as an infinitely large condenser, which is inadmissible, would be needed to get the temperature down to this—unless the principle of contrary flow were fully carried out—because air at 63 deg., for instance, would give up heat very slowly to water at 62 deg.; the air is delivered into the Hampson apparatus, no doubt, at a higher temperature by a few degrees than that of the atmosphere; but there can be no accumulation of heat, for reasons which will, I think, be obvious. We may say, then, that some 90 per cent. of all the heat due to compression is taken out in the cooler; the remainder escapes through the walls of the compressing pump, &c., the pump radiating freely because of the high temperature of the air in it.

Here I may with advantage digress, to direct attention to the fact that I am speaking of heat, not temperature. The heat may be taken out of air or converted into work at very different temperatures. It may be taken out in the cooler at 62 deg., and it may be taken out in the air pump at 300 deg. It would simplify matters, no doubt, if "Cryos" would avoid the use of the word "heat" altogether, and speak only of energy and temperature. Thus, then, he would understand that in the Hampson apparatus the energy remains unaltered, but the temperature varies in the same body of air, in just the same way that we have at the North Pole − 80 deg. and at the equator 120 deg.

If we turn now to the apparatus proper, we find that every portion of it is far below the temperature of the surroundings. The compressing pump is at a distance of several feet from the apparatus, to which it is united by a couple of small copper pipes only—one suction, the other delivery; because, it must be remembered, that the same air is used over and over again, additions being made to compensate for the small percentage of the total weight of air being liquefied. There may be 200 lb. or 300 lb. of air at a time in Dr. Hampson's apparatus, which is being liquefied at the rate of, say, half an ounce a minute.

Into the reason why air expanding is cooled, I do not suppose that "Cryos" needs any information. Concerning the so-called Joule's effect, however, I may say that, as has already been pointed out in your columns, it has nothing to do with the matter in hand.

After the air has left the cooler, there is no possibility of escape of heat or energy in any form. The air enters the apparatus, it is true, a little hotter than the cooler, but we may neglect this. For the rest, everything about the apparatus is colder than the surroundings, and so heat cannot escape. There is no external work done by the air in the apparatus. The result is that the great bulk of the air being worked on has an average temperature of a little over 62 deg., but, as I have said, at one end of the apparatus we have, say, − 200 deg., while at the other, in the pump, we have 300 deg. The Hampson process is simply one of getting two different temperatures at the same time in the same body of gas.

As to "Cryos'" suggestion about hydrogen, that gas will behave in all respects like oxygen and like air, only it is necessary to reduce the intrinsic energy of the gas to begin very much, and this can only be done by using a frigorific mixture in the surface condenser. Air cannot be conveniently liquefied without the use of a mixture of ice and salt in the cooler, but oxygen liquefies with the cooler at 60 deg. or a little less.

"Cryos" is in error concerning the work done by Professor Dewar. He thought on dogmatic thermodynamic lines, and used an apparatus costing some thousands of pounds, and totally different from Hampson's. He never dreamed, so far as is known, of applying the Hampson principle until after Dr. Linde and Herr Schröter had published the results of their inquiries. I call it the Hampson principle for convenience, but far be it from me to award originality to either Hampson or Linde. Professor Dewar has never claimed to have originated the process. The apparatus he uses was recently described in your pages, and differs from Dr. Linde's principally in the use of frigorific agents, such as liquid CO_2. If "Cryos" will look up the recent literature of the subject he will see that he is claiming more for Professor Dewar than that gentleman ever claimed for himself.

It may be worth while to repeat that the "permanent" cooling due to Joule's effect is much too small in amount to be of any commercial value whatever, and that no satisfactory explanation of the cause to which it is due has ever been broached. Lord Kelvin's so-called explanation is based on the pure assumption that the molecules of a gas attract each other—an assumption which appears to have been invented to explain the phenomenon.

April 13th. Zero.

LOCOMOTIVE FIRE-BOXES.

Sir,—I was much interested in seeing in your issue of March 28th the illustration of the new engines for the M., S. and L. Railway, and especially in the announcement of Mr. Pollitt's adoption of the Belpaire fire-box. It would be interesting to know why this form of fire-box has not received more favour from English locomotive superintendents, since it appears to be much liked on the Continent, and, I believe, is largely used on some of the Indian State Railways. I suppose one is right in assuming that the ordinary form of fire-box has satisfied English locomotive engineers for the last fifty years, and, if that is the case, what are the special merits of the Belpaire? It does not appear to have "caught on" in Britain. But is that due to sturdy conservatism, or to the feeling that the old-fashioned form is "good enough?" I have had something to do with the Belpaire, but, in case I am steeped in insular prejudice, I will say no more than that I am unable to see its special advantages. Could any of your correspondents enlighten me?

I have been much struck with the contrast between English and foreign practice in the manner of staying the crowns of fire-boxes. I have before me twelve types of English locomotives, and ten of these have girder stays, while two types have direct stays. Of ten continental types, nine have direct stays and one has girder stays; and, if I am not mistaken, direct stays find much favour in the Colonies. But the direct stay has been tried in England. Mr. Stroudley used it, and he said it was not a success, and went back to girders, and, unless I am mistaken, the late Mr. P. Stirling reverted to girder stays in his latest engines. Now, as outside of England the direct stay is almost universally used, and is therefore presumably a success, what are the causes which prevent its success in England? Is it insular prejudice, or is it that the girder stay is not only "good enough," but is the best? My own impression is that the answer will be found in a comparison of the cost of boiler repairs at home and abroad; and I have ventured to trouble you with this letter in hope that you may be able to deal with the subject in an early issue, and that any of your readers who have had experience will favour with their views on such an interesting subject. It is obviously more important than a wordy war about dates and "wind-cutters." Adriatic.

April 8th.

TYPEWRITERS.

Sir,—I do not know whether this subject has ever been discussed in your columns; if it has not, I venture to think it fairly deserves that honour, considering the growing use of these machines. I say growing use advisedly, because I am convinced that, were it not for the graspingness and short-sighted policy of dealers and manufacturers, that the public demand for these useful labour-savers would be infinitely greater than at present.

Primarily the excessive cost, which is absolutely prohibitive to many, is one of the causes, and is, I understand, due to a combination among makers to keep up prices. £20, the usual charge for a new machine, is an utterly absurd figure in these days when most of the patents have expired, and the instruments themselves are turned out by machinery by the hundred. Indeed, I believe, like modern bicycles, typewriters cost little more than £5 to produce, and could easily be retailed for some such price were it not for the existence of the before-mentioned ring.

Another matter which naturally influences the public is the fact that all machines now in the market are more or less imperfect. This may seem rank heresy to some, but it is the truth, nevertheless. One fault common to the whole genus, I believe, is this:—If the operator can see the writing he can never read what he has written, and *vice versâ*. This is a grave defect to everyone except mere copyists. The shift-key also, though not present in every typewriter, is an abomination wherever it occurs, and a serious impediment to that rapidity of work generally required. One objection to the shift-key is its position, almost invariably at the side, where it can only be manipulated by the "little," or weakest finger. Were this key placed in front of each machine—so that it could be worked by either thumb—with the touch board or boards at either side, much of the objection to its existence might be removed.

As to the "universal" key-board, I regard it simply as the direct creation of the Evil One in order to harass poor mortals; for every letter appears to have been carefully placed exactly where it should not be. As far as I can ascertain, this satisfactory result was arrived at in the first instance by the usual happy-go-lucky methods, and in these days of stick-in-the-mud conservatism no one has dared to introduce any alteration or reform in accordance with the dictates of common sense.

The perfect typewriter has yet to be constructed, but if anyone had spare time and energy to improve upon existing models, and introduce such machine at a cheap rate, a grateful public would quickly reward its benefactor. A Distracted Typist.

April 12th.

PERMANENT WAY.

Sir,—Referring to the recent accident on the Great Northern Railway at Little Bytham, and the subsequent article thereon in your columns of The Engineer of March 20th, I am induced to send you some particulars of an altered form of permanent way I conceived in January, 1883, and which is at the service of the Great Northern Railway or any other railway who may feel inclined to test it in practice on some short length of line, with a view of preventing a repetition of the above-named sad occurrence. The road I proposed was to be laid with flat-bottomed Vignoles rails, 4in. wide in bottom flange, laid on two longitudinal sleepers—minimum size 9in. by 3in.—sawn rakingly on upper surface to give the requisite "cant" to the rails, which were secured to same by coach screws. The joints were to be secured by wrought iron bed-plates—morticed in the longitudinal sleepers—and fish-plates carefully moulded to fit the rails.

The two longitudinal sleepers were to be bolted to transverse sleepers—ten in a 30ft. length—with fang bolts, and the road lined and levelled. Additional sleepers were then to be driven in between the ten sleepers above named, and ballast sufficient for complete "boxing up" added, thus making the bearing of the rails and longitudinal sleepers continuous. By the addition of the longitudinal sleepers, the road would be really more elastic in its actual construction than before, as the hard points of bearing in the customary iron chairs were thus eliminated, and road resistance diminished by the additional bearing given.

An ordinary cross-sleepered road would give, say, in a 30ft. length, the following bearing:—10 sleepers × 9ft. × 10in. = 75ft.; the new road would give 30ft. × 9ft. = 270ft., or 3·60 more sleeper bearing. Rail bearing, as for an ordinary chair-rail road, would give for rails:—No. 20 chairs × 6in. × 2in. = 1ft. 8in. bearing; the new road would give 2/30ft. × 4in. = 20ft., or 12·07 more rail bearing. And the weight of both locomotive and carriages being so well supported, it was believed that the running would be as smooth as if over a table, whilst in case of a "run-off" there would be less damage done to track and train, and inferentially to passengers or freight. The track, if it went down at all, would do so in long, easy slacks, and repairs would probably be much lessened. If necessary to lift the track the extra sleepers would be drawn out or driven out with the beetle, and again replaced after the road had been lifted and straightened.

In further reference to the late accident, the testimony of the guard describes the train as skidding down the greasy rails whilst sparks were flying up as if the train was on fire. This means that the wheels were locked by the action of the brakes, and from the intense friction each one would probably be found afterwards to have a flat place worn in its periphery. Here appears room for improvement to be effected by the skill of some master mechanic, who shall devise the means of applying the necessary friction resulting from braking to the rails direct, instead of, as at present, through the medium of the wheels. A wheel of 3ft. diameter can only offer a longitudinal friction on the rail head of 1½in. say, whilst if friction be applied to the rail at least 1½ yards may be obtained. The problem is how safely to apply the requisite pressure to the rail, without risk of lifting the vehicles from which it is applied dangerously, or catching ends of check rails, point rod coverings, &c. The problem is a difficult one, but I believe it can be solved by the mechanical ingenuity to be found so abundantly in this country. J. H. R. Rose.

3, Derby-road, Wrexham, April 13th.

Sir,—In a letter published in your last issue your correspondent, "J. C.," has gone to the root of the problem of resistance by treating it as useless work. He also points out the difficulty of apportioning the waste energy between the train and the road, and he appears to look for a remedy in improving the former rather than the latter. As my present theme is permanent way, I will neglect the work done on passengers and rolling stock, and confine myself as far as possible to the track.

To eliminate needless complications, let us suppose a straight and originally level road, and consider the resistance it opposes to a rolling load passing over it, which resistance is, of course, equal to the work done below rail level, minus whatever may be rendered back to the train by resiliance. If the road could be made absolutely uniform and absolutely rigid, no work could be imposed upon it, and it could offer no resistance. Neither condition is attainable, but, as "J. C." has observed, "a consideration of what is theoretically perfect often points the way to practical improvement."

In attempting to approach the ideal permanent way, we may easily find that of the two main conditions rigidity is, in practice, easier of approximation than uniformity; and hence the trouble with the "lathe bed" road in rock cutting, to which your correspondent, "F. J. P.," has alluded. The two conditions are interdependent—that is to say, the more uniform the road can be kept, the more rigid it may be made with advantage; and thus the want of uniformity is the beginning of evil.

The causes of this fundamental evil may, for convenience, be broadly divided between inherent unevenness in the track, arising from fish joints, intermittent supports, loose fastenings, weak sleepers, unequally packed ballast, &c.; and secondly, the long undulation which accompanies the rolling load. The former are accountable for shocks and hammering, and consequent vibrations set up in both train and track, and constitute, perhaps, the more important class as regards resistance, wear, and deterioration of material, and danger; whilst the latter imposes upon the locomotion that fruitless expenditure of power which has been compared to the labour of Sisyphus.

The mere enumeration of the faults included in the first category points to their remedies:—Longer, stiffer, and better fitted fish-plates, stiffer and longer rails, secure fastenings, improved sleepers, better ballast, and more attention to packing. It must be admitted that in the matter of rails, joints, and fastenings, modern English practice leaves little to be desired; but beneath the chairs there is less reason for satisfaction. The sleepers and the ballast have received less attention than they deserve.

Turning to the latter source of resistance—the great wave which causes the rolling load to press continually upon an up-grade when traversing a road originally level—it is easily seen that the resistance under uniform conditions is a constant retarding force $R = W \tan i$, W being the load, and i the inclination to the horizon of the tangent to the curvature of rails at the points of contact with the wheels; and if we knew the value of i, the number of foot-pounds per mile or per minute, at a given train velocity, could be of course ascertained by a simple arithmetical process.

Now this inclination depends upon the nature of the wave, which, on account of inertia, is probably deeper and shorter at slow than at high speeds, thus favouring the latter. But, on the other hand, it seems likely that the wave is more equimetrical about a vertical plane through the points of contact at slow than at high speeds; that is to say, for the same depth of wave, the inclination, i, would be steeper at high speeds.

In view of the practical importance of the matter, it seems strange that no efforts have been made, as far as I know, to ascertain the nature of this wave by actual observation. It is not, perhaps, so easy to do so as might at first sight appear, owing to what "J. C." calls "the earthquake" accompanying a train; but it is surely not beyond the powers of modern electricians and photographers to record what happens in a manner serviceable for the purpose indicated. However, in the absence of such records, we may, by the exercise of common sense, acquire some knowledge of the matter.

The wave is, at slow speeds, often very apparent to the eye, and is not at all a microscopic affair. It is certainly very much more than could be accounted for by the direct compression of the wooden sleepers; and, as the line returns nearly to its normal level after the passage of the load, it is difficult to believe that all this resiliance is due to the ballast and the formation below it. I am inclined to think that the greater part of the depression is due to the springing of the sleepers and displacement of ballast under the chairs. In other words, if the sleepers were twice as thick, or if they were repacked after the passage of each train, there would be far less wave; and I suppose no one could suggest that the road would be the worse in either case, whilst its resistance would no doubt be less.

If this is true, and if there is sufficient elasticity when the ballast is well packed, there must be too much elasticity—or too little stiffness—in the usual condition of the road; and it should be noted that too great flexibility in the sleepers is, to a great extent, the cause of the ballast being displaced.

The remedy I have suggested is the use of steel sleepers, which may be made of any degree of flexibility desired by adjusting their form, and without wasteful excess of material; and, moreover, the bearing area may be increased where it is most required, under the chairs, which is not possible with wooden sleepers. With properly designed steel sleepers there would be less disturbance of ballast, and, consequently, less packing required than at present, although I am aware that a prejudice to the contrary prevails.

As regards the nature of the ballast, I suppose it could not be contended that burnt clay, sand, gravel, broken stone, and cinders, are all equally good for the purpose. Assuming that they are not, and bearing in mind that the main cost is the first cost, it seems to me false economy to accept the first insoluble and porous material that presents itself in any particular locality as good enough for ballasting a railway.

I believe that the general opinion is in favour of broken stone; and, on *á priori* grounds, it seems to be the most suitable in having greater stability than rounded pebbles; in its freedom from dust, and the excellent drainage it affords; and in the uniformity of quality that can be insured by its use.

I hope, Sir, that you will before long revert in a leading article to the subject of permanent way which is still a very "live question." James Whitestone.

113, Queen Victoria-street, E.C., April 14th.

Sir,—The ink was figuratively—if not positively—not dry on the copy of The Engineer containing my letter of last week when the Snowdon accident occurred, where a slight depression of the permanent way resulted in the actual loss of one valuable life, and endangered scores of others. An entire page of your estimable journal would not suffice me to tell you what I think of the whole matter, practically and economically, and I will therefore do no more now than thank you for the prominence you are giving to the subject of permanent way, and express the hope that it will result in good for the travelling public.

As I read the report of the inquest in this day's newspapers, I gather that the manufacturers of the engines will not admit that their part of the work was in fault, and the makers of the line had to fall back upon the imperfection of the road, as "thawing after freezing possibly might have softened the ground and caused the depression." Can your readers imagine where the track-sleepers and all would be, with specially long fish-plated joints and a rigid rack also bolted to the sleepers, when the formation had left it—if not in mid air?

Perhaps, after a Snowdon accident as a beginning, some engineers may look closer to the dangers besetting the permanent way, before other accidents occur resulting in a much greater loss of life. J. W. Wilkins.

15, Lilford-road, S.E., April 15th.

CIRCULATION IN WATER-TUBE BOILERS.

Sir,—Whatever Professor Watkinson may think, it is to me clear that, as you have said, there is no circulation proper in the Belleville boiler, because the passage of plugs of water along the tubes is certainly not circulation. But Professor Watkinson has overlooked the important circumstance that, in his real boiler, no action of the kind takes place. It happens in the model; but only because it is a model.

Furthermore, those who like myself had an opportunity of seeing the model at work, must have noticed that the rate of evaporation was comparatively quite small. The heat available was very moderate, as compared to that from a real furnace. In text books we are told that the temperature of the Bunsen flame is very high; and it is taken for granted that when a Bunsen flame is used in a model boiler the temperature is very considerable. I have had a somewhat extended experience with models, and with real boilers. I have been working at water-tube boilers for over a quarter of a century, and more than 300 boilers of my invention have been made and put to work, and there is no record of a burst tube, or an accident of any kind whatever. But all this is history now, and I only mention the matter as an evidence that I know something of my subject.

Now, I used Bunsen flames, and I very soon found out that they are very treacherous, and may mean anything or nothing.

In a furnace such as the Thornycroft or Yarrow, the radiant heat from the fuel and fire-brick plays a most important part; but a Bunsen gas flame radiates practically no heat at all. We must have direct contact. A model boiler which would work beautifully with very powerful Bunsen burners, went mad when a charcoal fire urged by a good draught was substituted. The water, instead of circulating, was blown clean out of the tubes. Even with Bunsen burners Professor Watkinson burst the tubes of all the boilers he tried at the Institution of Naval Architects except the straight tube Yarrow. His experience is mine, only mine came when Professor Watkinson was at school.

A very good boiler may be made in which there is very little circulation. All that is wanted is to keep the tubes fairly well supplied with water. We may take a single tube and boil water in it with perfect success, with a little care.

The proper way to test the value of any boiler is a very cheap one, and was first suggested by Dr. Alban, from whom I have learned at least as much about water-tube boilers as from any one else. Make a full-sized model of a section of any proposed water-tube boiler of tin-plate soft soldered, work at atmospheric pressure; use not gas but coke, wood, or charcoal for a fuel in a properly enclosed furnace. If any overheating takes place, the soft solder will melt and tell the story. If the soft solder stands, the circulation is all right. That was how I arrived at my results.

The oil and water experiment suggested by your correspondent "Senex" is just what is to be expected, but it is not applicable to the case you have stated, for reasons which should suggest themselves at once. The oil and water column is not longer than the water column until the oil has separated itself from the water and floats on it. I accept Professor Watkinson's explanation of circulation as quite true. There is none other of which the same can be said.

Birmingham, April 14th. Old Tubulous.

Sir,—Having read a great many explanations as to the circulation of water in water-tube boilers, I am led to think that if, instead of commencing to explain as to the action of bubbles of steam in the water, the simpler plan would be to state what takes place at the earlier stages, when the water commences to be heated. Taking, for example, the case so frequently mentioned of the U tube with heat applied under one leg, I take it that the heat communicated to the water causes the water which has received the heat to expand and rise, and that the rising of this heated water commences the system of circulation, a fresh quantity of the colder water taking the place of the first water heated. If this be correct with *water*, one may fairly expect that it will continue after steam bubbles commence to form.

With regard to the relative weights of water in the two legs, the leg containing the heated, and consequently expanded, water must require to be longer than the "downcomer" leg with the colder water. Obviously, the pressure produced by the height of a column of water must depend on its weight; the heated column of water being lighter per unit of length than the colder column, would require a longer leg of hot water to make the balance in the two legs even. I find this to be the case when a pipe bringing hot water through a vertical pipe inside a tank delivers the water above the level of the colder water in the tank, the height of the internal pipe at which regular discharge takes place varying with the temperature of the hot water. Iron.

London, April 14th.

[Our correspondent forgets that, once boiling takes place, the water must be at practically the same temperature in all the tubes. The pressure produced by a column of water depends on the height of the column, and not on its weight.—Ed. E.]

THE CRYSTAL PALACE.

Sir,—Will you permit me to use your pages to direct the attention of the Crystal Palace authorities to the crying need which exists for facilitating access from the low-level station to the Palace. There are first two steep flights of stair to be climbed from the railway platform. Then comes a long weary tramp up a steep incline, at the end of which is another steep flight. Then comes a short bit of level and two more flights, another level, and two more flights yet steeper, and then the weary visitor finds himself in the Palace. To many people this is all very well, but to the middle-aged and the valetudinarian it is a very serious matter indeed.

And it could be so easily avoided. An electric tramway running where the old switchback did run would solve the whole problem as far as the Palace is concerned, and at halfpenny fares it would earn a fortune. Nothing has stood more in the way of the Palace than its inaccessibility. Now that a big exhibition is to be held of the means of locomotion, the glaring inconvenience of the existing method of getting into the building becomes more than ever prominent. Norwood.

April 14th.

THE SNOWDON RAILWAY.

Sir,—Having read the account of the opening of the Snowdon Railway to the public, it may be of interest to know that it is now sixteen years since the scheme was mooted. At the time the late Mr. Spooner, C.E., and myself planned a line from Llanberis to the top of Snowdon and down to Rhyddu on the Beddgelert side of the mountain.

Having taken much interest in mountain railways, I afterwards planned a line to the summit of Snaefell, in the Isle of Man, also to the top of Skiddaw, in Cumberland, and Ben Lomond, in Scotland, thus taking in the chief mountains in the British Isles. It was, however, too early for mountain railways in this country. The landowners would not agree to any arrangement for the land, and as such lines could not be put on the same footing as to public utility or necessity like railways in general, an Act of Parliament with compulsory powers could not be got.

I am glad, however, to see that matters have changed for the better. Out of the complete schemes which I have prepared as named, there are now two, viz., the Snaefell Railway and the Snowdon Railway, completed. The others will no doubt follow in time to be largely patronised by the British public.

J. S. Hughes, M. Inst. C.E.

Festiniog Railway, Engineers' Office, Portmadoc, April 9th.

ENGINE POWER IN PADDLE STEAMERS.

Sir,—For the information of your correspondent "Sponson." I am acquainted with a paddle steamer 225ft. long which has attained a speed of over 20 knots per hour, showing a coefficient

$$\frac{D^{\frac{2}{3}} \times V^3}{\text{I.H.P.}} = 242.$$

Your other correspondent, "R. B. S.," considers 19 per cent. of slip to be a full allowance for this type of vessel. I should like him to give an instance of any paddle steamer of 18 knots speed and upwards which shows less than 25 per cent. slip. To my mind the reason for such great power being required in Dutch steamers must be looked for in the model and position of shaft, as I find that very good results can be attained with short vessels and small wheels. Mareotis.

April 15th.

NAVAL ARCHITECTURE—NO. IV. STABILITY.

Sir,—Your correspondent, B. C. Laws, seems to consider that the height at which the ballast is placed in "inclining experiments" is only then of consequence when the angle of heel exceeds 10 deg.

I differ with him entirely in this respect, and consider that the height or depth of W above or below G must always be allowed for by calculation to obtain accurate results. The loss or gain in M G is only a matter of proportion.

My object in writing my first letter to you was to direct the attention of beginners to the fact that the ordinary formula for finding M G by inclining experiments does *not* take note of the position of the ballast to be shifted, and would give the same height for M G whether the ballast was any number of feet above or below G. The angle of heel is all that is considered.

It is always necessary to correct the metacentric height obtained by formula by a calculation of the influence of the height above or below the centre of gravity at which the shifted ballast is placed.

April 11th. F. W. C.

HORSELESS CARRIAGES.

Sir,—Having just returned from a tour of inspection in France, made for the purpose of ascertaining the present position of automobilism, I think it advisable to at once advise my brother engineers through your valuable instrumentality of the fact that I am officially informed by the secretary of the Automobile Club of France that the carefully planned trial of "automobiles" between Paris and Marseilles, which it has been arranged should take place in July, has been postponed until October.

I cannot here give the result of my investigation of the subject of continental self-propelling road vehicles more than to say they still leave much to be desired, and I therefore hasten to make known the fact of this postponement in the hope that it may be of value to English engineers proposing to build vehicles for entry in friendly rivalry with our neighbours in these races.

I shall, moreover, be pleased to give any further information in my power. Alfred R. Sennett, A.M. Inst. C.E.,

Hon. Executive Commissioner International Horse and
Horseless Carriage Exhibition, Crystal Palace.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies*

F. B.—*See* THE ENGINEER, *19th July and 9th August, 1895.*

C. W. R. (Devonport).—*Your idea was illustrated and described during the discussion on water-tight doors. The great space occupied is a serious objection to the scheme, which was simply ignored by those who took part in the discussion.*

H. G.—*There is no special treatise on governors such as you ask for. The subject has been fully dealt with in almost every treatise on the steam engine, while papers have been read about them in considerable numbers. The eighth chapter of "Goodeve's Treatise on the Steam Engine" will probably answer your purpose.*

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

HULL AND DISTRICT INSTITUTION OF ENGINEERS AND NAVAL ARCHITECTS.—Monday, April 20th, at 8 p.m. "Paper: "Narrow Gauge Railways," by Mr. J. B. Hutchinson.

SOCIETY OF ARTS.—Monday, April 20th, at 8 p.m. Cantor Lectures. Paper: "Precious Stones," by Professor Henry A. Miers, M.A. Lecture II. Wednesday, April 22nd, at 8 p.m. Paper: "The Perfected Photochromoscope and its Colour Photographs," by F. E. Ives. Thursday, April 23rd, at 8.30 p.m. Indian Section. Paper: "The Deserted City of Vijianagar," by Captain Charles Rolleston.

ROYAL INSTITUTION OF GREAT BRITAIN.—Saturday, April 18th. Afternoon Lectures, at 3 a.m.: "The Vault of the Sixtine Chapel (I.)," by Professor W. B. Richmond, R.A. Tuesday, April 21st. "Child Study and Education (Lecture II.)," by Professor James Sully, M.A., LL.D Thursday, April 23rd. "Recent Chemical Progress (Lecture II)," by Professor Dewar, M.A., LL.D., F.R.S., M.R.I. Friday, April 24th, at 9 p.m. Paper: "The Circulation of Organic Matter," by Professor G. V. Poore, M.D., F.R.C.P.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 21st, at 8 p.m. Papers to be discussed: "The Thirlmere Works for the Water Supply of Manchester," by Mr. G. H. Hill, M. Inst. C.E. "The Vyrnwy Works for the Water Supply of Liverpool," by Mr. G. F. Deacon, M. Inst. C.E. Thursday, April 23rd, at 2.30 p.m. Students' visit to the Linde British Refrigeration Company's Works at Lower Shadwell.

"THE ENGINEER"

1100 GUINEA ROAD CARRIAGE COMPETITION.

We are now able to publish the full conditions which will apply to our competition. They will be found on page 385. Many of our readers will perhaps be glad to note that we have seen our way to add another substantial prize to the list previously announced.

THE ENGINEER.

APRIL 17, 1896.

ENGINEERS OF THE ROYAL NAVAL RESERVE.

IT will probably be news to the majority of our readers that there exists a Royal Naval Reserve of Engineers. It is well known that there is a Royal Naval Reserve of officers and men, but the engineer branch of the same reserve is in quite a different and indeed obscure position. The R. N. E. R., as it is commonly called, exists more in name than in fact, and yet strangely enough the Admiralty appear to rely on it to help them out of difficulties. Probably nothing more remarkable or anomalous is to be found in the whole of our naval policy than the history and position of this body of marine engineers. On the 17th of March Mr. Cooper read a paper before the Institute of Marine Engineers, which contains probably all the information which exists on the subject. It was followed by a discussion which extended over a couple of evenings, and to this paper and the discussion we are indebted for most of our facts.

From the earliest period of the introduction of steam into the navy there has been a scarcity of engineers. About sixteen years ago the Admiralty determined to form a reserve of mercantile engineers who would be willing to serve, when called upon, in her Majesty's ships. We reproduce the conditions of service in a somewhat condensed form:—"The officers of the Royal Naval Reserve are to rank with, but after, officers of the Royal Navy of their corresponding rank. A senior engineer must hold a first-class engineer's certificate; have had at least three years' service in sole charge of machinery of a high speed British ship of not less than 500-horse power, and not less than eight years' service at sea as an engineer. An engineer officer must hold a first-class engineer's certificate, and have served at sea for at least three years as a certificated engineer, and have had at least one year's service as chief engineer of a British ship of 200-horse power, or as second engineer of a high-speed British ship of not less than 500-horse power. An assistant-engineer must hold a first or second-class engineer's certificate; have served at sea on a British ship for not less than one year as a certificated engineer. The age on first appointments of officers shall not exceed—for senior engineers, 50 years; engineers, 40 years; and assistant-engineers, 30 years. Officers of the Royal Naval Reserve are to wear the same uniform as officers of corresponding rank in the Royal Navy, with a few slight exceptions in buttons, braid, &c. Officers of the Royal Naval Reserve will be called out for active service by Royal Proclamation, and they will be liable to serve during the continuance of any national emergency, or until they may be regularly discharged by the direction of the Lords Commissioners of the Admiralty. Officers whilst embarked for voluntary service or for naval training will be subject to the Naval Discipline Act, and will receive the same pay and allowances, and share in prize money, with officers of the corresponding rank in the Royal Navy, and they will whilst on service be treated in the same manner in every respect. Officers who may receive hurt or wounds whilst on active service in the Royal Navy, or whilst undergoing drill, will receive the same pensions and allowances to which officers in the Royal Navy would be entitled under similar circumstances. Widows and children—if any—of officers who whilst on actual service may be killed in action or die from accident resulting from the performance of their duty will receive the same pensions as the widows of naval officers of corresponding rank would be entitled to under similar circumstances."

All this appears to be reasonable enough, but it is only reasonable on paper. The oldest commission held by a Royal Naval Reserve Engineer dates back to 1881. At one period a good deal of pressure was brought to bear to induce men to join, but according to the last Navy List, while the Admiralty provides for 150 engineers and 150 assistant-engineers, the total number on the list is 149 senior engineers and engineers and 52 assistant-engineers. Thus, then, while the Admiralty have asked for 300 men, they have got but 201. The smallest number of engineers that will suffice to man our ships in war time is about 1100. According to the Navy List, we have about 800 available, and the Reserve men. For full information on this point, however, we must refer our readers to the table prepared from official sources published in our impression for March 7th, 1895. It is not our purpose now to go into the question of how many engineers are wanted. It will be enough if we say that there is absolutely no provision whatever made for the loss of engineers in service. The Admiralty appear to think that the naval engineer is endowed with a charmed life, and that he will neither break down mentally nor bodily during war-time, and that he will never be shot or drowned. or scalded to death. In short, engineers are never to be "expended." Common sense tells us that, although a ship in time of peace may do with two engineers, or even with one, in time of war the number should be doubled. But leaving this question, let us consider why and how it is that mercantile engineers have not enrolled themselves in the reserve. The explanation is simply that they have nothing to gain by the enrolment. It is about as useful as a foreign order; there is no pay attached to it. It does not confer position. It does not teach. It is very frequently, and no doubt truly, said that if war broke out hundreds of merchant steamers would be laid up, and that from their engine-rooms the Admiralty could obtain plenty of men but the men so obtained would be in all respects on the same footing as the men of the R. N. E. R. What possible inducement, then, exists for joining that body now? None that we can see.

When the Reserve was formed it was generally believed that the men of the Reserve would undergo a special training to fit them for service on board men-of-war, but nothing of the kind takes place. Some misapprehension exists on this point. We have often heard it argued—and the argument was freely used in the course of the discussion on Mr. Cooper's paper—that the mercantile engineer who holds a chief's certificate is competent to take charge of the machinery in any ship of war at a moment's notice. Now we mean no disparagement when we assert that this is a thorough mistake. The man whose experience has been confined to triple-expansion engines, with long connecting-rods, indicating from 800 to 2000-horse power, and making 60 revolutions per minute, is not thereby qualified to take charge of engines indicating 4000 or 6000-horse power, with short connecting-rods, and making 160 to 180 revolutions per minute. We say nothing of forced draught. The cramped space in the engine-room of a ship of war is enough to strike the inexperienced with dismay. But even if we admit that the mercantile engineer knew all about the machinery of the warship, it still remains a fact that he can know nothing about the life on board a man-of-war—the rigid discipline, the special conditions under which he would have to live and move and have his being. As one speaker said, the newcomer would not even know from their uniforms the relative rank of the executive officers. The obvious remedy is, of course, to give all the engineers of the Reserve an opportunity of acquiring practical insight by taking them on board men-of-war in commission. All the other reserve forces of the nation get practical training, and in many instances this training is very thorough; in none can it be called superficial. Mr. Cooper, in his paper, advocated a training of twelve months on board ship. We agree with several of his hearers that the period is too long, and it would not take account of progress. Thus, for example, a man who had twelve months' training in 1896-97, and was not called on to serve again until well into the twentieth century, would be very little better off than the man who had not served at all. The proper course is each year during the naval manœuvres to draft for service on board a certain number of engineers of the Reserve to act as supernumeraries. Their presence would be a very welcome relief to the strain now put on the engine-room staffs, and the opportunities for learning would be very considerable. By taking in this way a couple of dozen men every year, the whole body would by degrees be passed through the Navy. This service should be compulsory, but, of course, properly paid for; and there would be very little difficulty met with in avoiding the infliction of any hardship. But besides this compulsory service, special facilities should be provided for giving a longer training, say three or six months, to those who desired it. We have no doubt but that this training would be highly popular, and that the ranks of the R. N. E. R. would very quickly be filled to overflowing under the new conditions. It is impossible to overrate the valne of a body of 500 or 600 men, fairly well versed in the routine of life on board a man-of-war, and possessing some practical acquaintance with the highly specialised steam engines used in propelling them. So great are the advantages, indeed, to be secured in this way, that we find it impossible to frame any legitimate explanation of the curious policy pursued by the Admiralty. They do not consider any man competent to take charge of machinery in a ship of war unless he has undergone a most expensive and elaborate training; and yet they are content to accept an engineer out of a tramp steamer without any special training whatever in war time, when experience and special knowledge are most needed. The only feasible explanation of the matter is that the Admiralty regard the R. N. E. R. as a sham—a thing got up to meet a political temporary difficulty, and consequently my Lords will not spend sixpence to render the Reserve really efficient. Truly, the ways of Whitehall are wonderful. Possibly the authorities think that ships of war are still propelled by sails, and only make believe that the sailor is extinct and the engineer has taken his place.

BOILERS FOR ELECTRIC LIGHT STATIONS.

THREE of our electrical contemporaries have done us the honour of considering at some length our article on "Boilers for Electric Light Stations," which appeared in our impression for the 27th of March. One of them has reprinted the article. All three criticise our statements, but they are not agreed among themselves. It will be remembered that we stated that the Lancashire boiler, as used in mills, was as well adapted for producing electricity as cotton cloth, and we added that electric light engineers were beginning to find this out, and that the water-tube boiler was by no means the only one adapted to his wants, or competent to satisfy his wishes. The comments of the *Electrician* are not the least interesting of the criticisms to which we refer, and to them we shall for the moment confine our attention. Our contemporary begins by saying that it is "not unnatural that the mechanical engineer should regard an electric light station as nothing else but a factory, and often fail to see why the mill engines and Lancashire boilers have been discarded." Now, as a matter of fact, the mill engine is used pretty freely; but we are not now dealing with engines, and need not further refer to them. Confining our attention, then, to boilers, we find that our contemporary after all not only admits that the Lancashire boiler will do, but that it is doing to such an extent that over 60 per cent. of the boilers used in the provinces for the production of electricity are of the Lancashire type, while only 22·3 per cent. are of the water-tube type. "It is only in the metropolis that the compact inexplosive boiler has a prominent place." The *Electrical Review* says much harder things of the water-tube boiler than anything we have uttered, while of the Lancashire boiler it says:—"As a matter of fact, a Lancashire boiler can be made equal to its 160 lb. or 200 lb. pressure easily enough, and it is then far safer than water-tube boilers, and will remain safe and in good order for a period of time sufficient to end a boiler of locomotive type, and to renew a water-tube boiler several times over. It thus happens that both in first cost, steam dryness, efficiency, upkeep and scrap value, the Lancashire boiler has not yet been equalled by any other type for genuine hard work, and as it can hardly be fired to the extent of damage, and so can burn coal at a greater rate per square foot than its rival, there appears no reason to suppose that, in well-designed electrical works, it will be found absent to anything like the extent that has been the case in the past."

The *Electrical Engineer* holds that the Lancashire boiler will not answer where the load varies considerably, and goes on:—"In the electric light stations in London the water-tube boiler has carried all before it, and we would uphold this practice. The chief reason for this result has doubtless been its quick steaming properties. The electric light supply must necessarily be continuous, and the sudden demand when a fog arises in London could not be met with Lancashire boilers without considerable loss due to boilers standing under steam." But it adds that the Lancashire boiler does very well in such towns as Bristol, Newcastle-on-Tyne, Manchester, and some other towns named; and, further, it claims that where ground space is very valuable the water-tube boiler has a great advantage. So much for our contemporaries. We may now proceed to call their attention to a few facts which they have not unreasonably overlooked. We take it for granted that their criticisms in question have been written by electricians or electric light engineers; and it is no discourtesy to assume that these gentlemen have had practically no personal experience with the Lancashire boiler; nor do they know at first hand what it can and what it cannot do. They are in precisely the same position as the gentlemen who first put up electric light installations, who knew nothing practically about the Lancashire boiler, and adopted the water-tube boiler for reasons which we have already fully explained and need not repeat here. This ignorance has led our contemporaries to make certain statements which are contrary to the facts. The first is that the water-tube boiler is a necessity, because steam can be got quickly in it, and cannot be got up quickly in the Lancashire boiler; and the necessity for getting up steam quickly is the sudden advent of fogs. Now a very moderate acquaintance with Manchester would convince our contemporaries that the metropolis does not stand alone in the matter of fogs, and that if Manchester can get on with Lancashire boilers so can London. But the sudden advent of fogs is a very rare occurrence, and can only affect the proceedings of the electrical engineer when it occurs in the day time. Every night those in charge are ready for their load, and that is the same to all intents and purposes, fog or no fog. It is a complete mistake to imagine that a water-tube boiler can be rushed in the way our contemporary supposes. Any attempt to do that will bring a more or less heavy reckoning. In an electric light station, provided with Lancashire boilers, steam would never be let down in those on duty. The dampers would be closed and the fires banked. These boilers would stand for twelve or fourteen hours, neither making nor losing steam, with an extremely small consumption of fuel. In case of emergency, they could be got into full work in a number of minutes fixed by the getting away of the fires; the water in them is boiling hot, and with a good draught the fires soon burn up, if they are not smothered at the outset by an injudicious fireman. Fifteen to twenty minutes ought to suffice to get a Lancashire boiler into full work from the moment the dampers are raised and the fires drawn forward. The water-tube boiler, on the other hand, "stands" very badly. The volume of water in it is small, and the size and shape of the grate are such as to make banking without an extravagant consumption of coal, very difficult. Let us suppose that three large Lancashire boilers supplying, say, 600-horse power each, are sufficient for the top load of a station. All three will be under steam. One takes the day load, perhaps 300-horse power, with the dampers partly closed. As the load augments the dampers are drawn. Then the second boiler is started, and finally all three are in use. Now, the advent of a fog in the daytime could only mean drawing the dampers, say, at 10 a.m. instead of 7 p.m.; and we have not the smallest hesitation in asserting that working in this way less coal would be burned than would be needed to light up each afternoon a couple of water-tube boilers which had had their fires drawn the night before. We say this as the result of practical experience with water-tube, Lancashire, and locomotive boilers. Of course, it is possible to work the Lancashire boiler with disastrous results. It is only necessary to draw the fires and let it cool down every day to secure that undesirable end. But any man who understands how the boiler ought to be managed will find that it is just as ready to meet an emergency as any other type in the market.

The second erroneous assumption made by our contemporaries is that the space occupied by the water-tube boiler is much less than that filled by Lancashire boilers of equal power. This is very far from being necessarily true. We need scarcely tell our readers that the water-tube boiler bears forcing very badly. It is one thing to have heating surface, and another to be able to make use of it. We think we may venture to say that the power that can be got out of a set of properly designed Lancashire boilers in a twelvemonth will be at least as great as that which can be got out of a set of water-tube boilers filling the same ground space in the same time. The time required for cleaning must be included in our calculations. It would be interesting to know what percentage of all the water-tube boilers in any given installation—say the City of London for example—is available for steam making all the year round. This is the proper way to look at the question. If a water-tube boiler has to be cleaned every five weeks, and a week is spent in the cleaning, then it is clear that not more than 80 per cent. of the boiler power is at any time available; and the fact must be taken into consideration in estimating ground space.

Lastly, we may point out that the water-tube boiler possesses certain advantages, and should always be used when these advantages can be displayed. A waterproof coat is an extremely useful and even necessary garment at times; but it does not at all follow that it is really the best coat a man can wear. The talent of an engineer is shown by the way in which he adapts himself to circumstances, and selects out of the multitude of expedients presenting themselves that which is most suitable to the circumstances. It would be very bad engineering to spend large sums in pulling down buildings in order to make a road for a large Lancashire boiler into some of the contracted courts of London while a water-tube boiler was ready to hand. In engineering there is a proper place for everything. Our quarrel, if such it may be called, with the electrical engineer is not that he has used the water-tube boiler, but that he has adopted it to the exclusion of that type which by long and excellent service has proved its claims to consideration. We confess that until we had read the statement which we have quoted from a contemporary, we had no idea that the weight of these claims had been so fully recognised in just those places where the most extended experience in the production of steam is available for the guidance of the electrical engineer.

THE DISCHARGE NOTE SYSTEM IN COLLIERIES.

There was an issue raised of more than local concern in the Discharge Note crisis, which, for a while, threatened the South Wales and Monmouthshire coalfields with a calamitous strike. The representatives of The Engineer in those districts have informed our readers of the origin of the problem, and the happy solution which was found for it. There is no fear of a strike now, or any reason to fear a strike in the immediate future on this particular point of South Wales colliery regulations. The position nevertheless was grave, and if the acuteness of the gravity has been diminished, it leaves the original questions open for discussion on either side, and for the matter of that, in every coal mining region in the kingdom. The cause of the troubles in South Wales was the sudden and, as it appears to us, the injudicious enforcement of a practice of requiring every miner seeking employment in another pit to produce a circular letter of recommendation from his former manager. It meant this, that no man should be taken into occupation who could not show "a clear discharge," as it is called, in the mercantile marine. There is little doubt that the Discharge Note was an institution at a few collieries in the district twenty years or more ago; and then the men, so far from being averse to it, welcomed the document as a voucher to their skill and character. Of recent years, however, the custom appears—with one or two exceptions—to have fallen into disuse, until, a few months ago, the South Wales Coalowners' Association determined to revive it, and make it of universal application in the collieries under their control. So long as it remained in practice in a pit here and a pit there it was at least tolerated. It was when the employers directed that the Discharge Note system should be made obligatory everywhere that the colliers revolted, and began to exhibit an indignation and resentment which so cautious a miners' leader as Mr. W. Abraham, M.P., described as more ominous than any outburst of feeling he had known since the sliding scale was established seventeen years ago. The protests were general, and proceeded directly from the colliers, not from their agents on the Sliding Scale Joint Committee. The withdrawal of the note was demanded or a strike was the alternative, and only by a majority of ten votes in a delegate meeting representing 93,000 miners was a strike averted pending renewed negotiations with the Coalowners' Association. Well, that is all over, and because it is all over it is additionally well.

It is not easy at a distance to discover the secret of an agitation which came so near to being a catastrophe. It is certainly difficult to understand why the coalowners should have taken up a position from which they have already in a measure been forced to recede; or why the colliers should have shown such a temper over a regulation, which, even if an innovation, must operate as much to the benefit of the skilled and steady workman as to the detriment of the ne'er-do-weels, who are no fewer among the Welsh colliers than in other mining communities. Some facts, however, are on the surface, and with these and a recollection of the bitter contention over the almost similar "character note" in the Northern coalfield in the seventies, it is possible to explain, and perhaps with some profit, the causes of what momentarily looked like a very dangerous position. The employers are continually being urged by the miners to institute safeguards against the admission of unskilled men to the underground workings. That has been the theme of fervent speeches at trade congresses and miners' conferences for time out of mind, and more than once the wisdom of Westminster has been invoked, though without effect, to put a check upon the underground employment of all sorts of casual labourers and hobbledehoys. Whether the Discharge Note would or would not serve that purpose—whether a less obnoxious means of ascertaining a man's competency could not be adopted—may be an open question. It is intelligible, at any rate, that the South Wales coalowners should have thought that they had hit upon a serviceable device to protect the trained miner from the amateur, and at the same time secure for themselves efficient service in the workings. It is claimed, moreover, that the Discharge Note would place a check upon a practice which vexes the soul of every colliery manager, and nowhere more than in Glamorganshire. Every one connected with mining operations is familiar with a class of men, unmarried men as a rule, who drop their tools after two or three days' work, or who will not descend the pit until mid-week, or who seize the flimsiest pretexts for finding fault with the timbering, or the ventilation, and sow the seeds of discontent wherever they go. A note which indicated the reason for the dismissal of a man of this kind, it is argued, would operate as a timely warning to other managers to whom he might apply for work.

But the strong point in the remonstrance of the South Wales workmen, and one that seems to have been practically admitted, is that the introduction of the Discharge Note is a breach of the sliding scale agreement of 1879, which provided that no alteration in the customs of the trade should be valid unless approved after consultation between the two parties on the Joint Committee. Other objections strike much deeper, but there the men are upon less stable ground. They complained that the note system is not only open to abuse, but was being abused. It enabled a spiteful or capricious manager, they say, to "mark" a man by some cryptic sign on the otherwise fair-seeming paper, and thus prevent him from gaining employment anywhere in the coal basin. The Welsh miner is possibly no more superstitious than his fellows, despite his delusions about the "red dog" and the "voices" as the forerunners of an explosion; but he has more than the ordinary Celt's share of suspicion, and it has manifested itself in connection with the Discharge Note agitation in a manner which would be ludicrous but for the seriousness of the issue then impending. The Discharge Note shall be clean on the surface; and, in fact, to all appearance as good a recommendation as a collier can desire. Workmen have actually been known to hold it to the light, and scrutinise it dubiously, because the report had been spread that the watermark bore a mysterious message from one manager to the other. Nonsense of this description is, of course, beneath notice. The allegation that the Discharge Notes were privately endorsed by colliery officers—though the charge appears incredible—was deemed important enough to be dealt with, and the Coalowners' Association issued a circular to pit managers enjoining them strictly to observe, and add nothing to, the printed form. But the main fact is that the Discharge Note, more especially the manner of its introduction, was resisted—and very angrily resisted—by close upon 100,000 colliers, who threatened to strike work if the employers persisted in its use.

It would be a thankless task from any point of view to discuss the question as to who was responsible for the Discharge Note fiasco in South Wales. It would appear from the information placed at our readers' disposal from the Principality that the colliers themselves would have been glad to accept certificates of competence if they had only been consulted beforehand. The one question, serious as it might have been, raises a question which may become more serious still. The position of mine-owners is changing with the course of the years. We used to have the "Father of the Mine," literally the founder of the industry, which occupied four or five hundred hands. The collieries now-a-days in the West as in the North seem to be day by day being converted into limited liability companies. The transmutation is a good thing in its way, no doubt, but it alters very materially the old relations of master and man. The situation we have been describing can be summed up in a compendious sentence. Under the old private ownership Discharge Notes were never thought of, never needed. They may be necessary in this later time; but the necessity, it may fairly be suggested, is caused by the people who have created the changed conditions.

◆

COPPER MINING IN SPAIN.

Perhaps the most notable of the mining companies that British capital has formed to work in Spain is the Tharsis Sulphur and Copper Company, and it is certainly one of the most lucrative. In twenty-nine years it has had gross profits to the extent of £8,343,378; and after providing for depreciation, reserves, &c., it has divided more than £5,500,000 amongst its shareholders. In its last year it extracted from the famous Tharsis mines 278,441 tons of mineral; and at the Calanas mines the mineral extracted was 298,424 tons; whilst the extraction of ore has now been begun at the Lagunazo mines, 35,618 tons having been obtained. Thus, the Tharsis Company raised at its mines over 612,000 tons of mineral last year, and the copper produced showed a considerable increase on that for the preceding year. By the policy of writing off depreciation liberally, the value of the property is kept low. The original value, for instance, of the Tharsis and Calanas mines was £709,228, but £564,228 have been written off, so that the book value of those two great mines is very moderate; and this is the policy pursued with other property. It is thus partly to the low price at first, to the system of writing depreciation out of profits, and the comparatively low cost of production of the mineral in Spain, that the great mining companies of which the Tharsis is the type have been able to realise profits that are undoubtedly large. For instance, in the company of which we have given the above particulars, the average dividend since the formation has been slightly over 17½ per cent. per annum on the average—a return that must be considered an excellent one. As a matter of course, it has been aided by the fall in the freight for the ore from Spain to the smelting and extracting works—the rate being about half what it was. Naturally the price of copper, as well as of sulphur, has fallen considerably, but the enlargement of the output and the making of a fuller use of the mineral raised has been in degree a counterpoise. There are few industries in which there has been so marked a removal of the waste as is now the case in the sulphur-copper ore treatment, and hence there is the very admirable result that has been indicated; and should the movement in prices continue upwards, it is quite probable that the results of the next year to be reported on may prove even better than those of the last.

LITERATURE.

Life and Letters of the late Admiral Sir Bartholomew James Sulivan, K.C.B. 1810—1890. Edited by his son, Henry Norton Sulivan, with an introduction by Admiral Sir G. H. Richards, K.C.B., F.R.S. London: John Murray. 1896.

During the last few years there has been a happy increase in the number of naval biographies and books on naval subjects. This is as it should be. A people so largely dependent upon a navy as we are cannot neglect any means of arousing and maintaining a popular interest in naval subjects. Mr. Sulivan has done good work in giving to the world this life of his father, and his brother, Commander Sulivan, is doing the like for their maternal grandfather, Admiral Bartholomew James, whose life will form one of the publications of the Navy Records Society. Admiral Sulivan was a remarkable man in many ways, and in his own branch of the service probably no officer excelled him in seamanship and the peculiar qualities which go to the making of a navigator and hydrographer. His training began as midshipman of the Thetis. In 1828 he joined the Beagle, under Fitzroy, who had been lieutenant of the former vessel. The six years passed by him in the Beagle in the tempestuous region of the Magellan Straits and Cape Horn were such, Admiral Richard says, as few men had experienced, and it is not too much to suppose that the experience so gained went a long way in the forming of that reputation which he afterwards acquired for judgment, coolness, and promptitude of action. He subsequently commanded the Philomel, which was engaged in the surveys of the Falkland Isles, the river La Plata, and the upper waters of the Paraguay and Parana, and it was while so employed that the combined operations of the English and French squadrons against the Dictator Rosas in 1845 gave him ample opportunities for the exercise of his special qualities as a strategist and pilot. How magnificently he succeeded, how he safely piloted the ships, with one or two exceptions without steam power, for months in difficult and almost unknown waters, to the admiration of both squadrons, must be read in the book itself. In 1854, when we were at war with Russia, he was appointed to command the Lightning paddle-steamer of three guns, the first steam vessel built for the Navy. His instructions were to join Sir Charles Napier in the Baltic, for surveying and pilotage duties. Sir Charles did not receive him very cordially. He told Captain Sulivan, before several officers, that he did not know what he had come out for, or what was the use of a surveying ship, unless to make a fire vessel of! However, after many disappointing, not to say irritating experiences, the value of the "surveying ship" and her commander were ultimately recognised by the admiral, and still more warmly by his successor, Sir R. A. Dundas. The long and detailed accounts of the almost daily work of the fleet in the Baltic which Captain Sulivan sent home in his letters to his wife, under strict injunctions to treat them as confidential, are deeply interesting, and it is not too much to say that they form an important contribution to the history of our naval operations in those parts. We have not space to make extracts from them, we can only recommend them to the perusal of our readers, who will find much in them of interest from a professional point of view, and will derive not a little pleasure and amusement in drawing comparisons between the then and present conditions of our Navy, comparisons which make strikingly conspicuous the changes which forty years only have brought about. What should we think now-a-days of a captain who, in a moment of emergency, did not hesitate to force a large frigate by press of sail over an extensive reef in a gale of wind, when every blow in the hollow of each sea jerked up the boats on the upper deck? Yet Captain Cooper Key's proceeding does not seem to have been exceptional. Indeed, Captain Sulivan expressed an opinion that iron vessels were not useful for surveying, because they would not bear knocking about on the ground. The steamers of our fleet at that time seem to have had a speed of 8 or 10 knots. One of Captain Sulivan's letters tells us that "the James Watt, built especially for the screw, has expended 45 tons—of coal—to keep her station during the last twenty-four hours, whereas the old lump of a three-decker—Royal George—has only expended 33 tons, though under sail a slower ship. We—the Merlin—have done much the best of the paddles, having, with 312-horse power, only used 12 tons; Firefly, of 240-horse power, 16 tons; and Locust, of 100-horse power, 10 tons; little Lightning, 100-horse power, 5 tons." Cholera seems to have attacked the crews of the steam vessels, while the ships companies of vessels which had no steam power escaped. This was put down to the heat from the boilers. In proof that there is nothing new under the sun, we find Captain Sulivan elaborating with his brother a scheme for sounding operations at the barrier in the Cronstadt Channel, to be conducted by them in something very like Boyton swimming dresses. Again we have an account of the trial in Poole Harbour of a submarine boat, which, by the way, nearly drowned its occupants. This boat is described as like a large inverted whale boat of iron, with a chamber at each end filled with compressed air. It was lowered keel uppermost, the crew being under the thwarts. When the boat was allowed to sink nearly to the bottom, the men got down and, with their heads in the air-filled boat, pushed it along as they walked on the ground. It was intended for use against the boom at Cronstadt. The volume contains an illustrated description of the submarine mine, or "infernal machine," used by the Russians in the Baltic. It differs in some respects from that used by them in the Black Sea, an illustration of which, if we remember rightly, appeared in the *Illustrated London News* of the time. The volume is supplied with an excellent map of the Baltic.

Proceedings of the United States Naval Institute. Vol. xxxi. No. 4. Whole No. 76.

It is possibly because we do not anticipate a conflict with the United States Navy that we in England do not regard it with that attention and interest which we devote to the navies of other Powers. We are wrong in this comparative indifference, not from any political point of view, but from a purely scientific one. The American navy is a navy of experimental vessels, and is, therefore, worthy of the keenest scrutiny, for whether failure or success attend them, experiments costing some millions of money are not to be lightly regarded. In the new United States battleships that skyward tendency which is so well marked a characteristic of American work, as shown in multiple-storied houses and "cloud-capped" funnels, is again exemplified. The turrets of the new battleships are two-storied; on the lower level are placed two 13in. guns, and on the upper level two 8in. guns. The double turret is trained as a whole, so that all four guns point simultaneously in the same direction, except in so far as affected by the angles of elevation. Ensign Joseph Strauss contributes a paper to the current number of the "Proceedings" of the United States Naval Institute, setting forth the reasons that have led to the adoption of this peculiar arrangement. The principal of these are the economising of space and the reduction of weight. Various other arrangements have been tried or proposed, but all have drawbacks. In one, in order that the zone of fire may not be reduced, four turrets, each with two 8in. guns, are used; in another design the 8in. turrets are directly behind and above the 13in. turrets; the objection to this arrangement is that the blast from the overhead guns, however, damages the structures beneath, or interferes with the lower gun crew, so that the design is not practicable. To the writer of the paper the arrangement adopted appears to be nearly perfection. All the difficulties raised he disposes of entirely to his satisfaction; the concentration of weight is nothing, it is not as great as on the Victoria—an excessive case, by the way—the training of all four guns on to one point is "not an objection;" the risk of having "all one's eggs in one basket" is counterbalanced by the omission of at least two entire sets of rotating gear per ship, and so on; and the advantages are, reduced target, simplicity, and "best possible command," &c. This is all very well, but it seems to us that a very serious point has been disregarded, that is, the strain produced if all four guns are fired simultaneously. It is well known that the greatest difficulty the naval constructor has to contend with in building his emplacement for large guns is the necessary structural strength to withstand the tremendous recoil blow. Two guns on one centre have been as much as any one has cared to face up to the present, and such marked success has not attended them as would warrant adding at least fifty per cent. more to the stress. It may be that means will be taken to prevent the four guns firing at once—that in itself will be a drawback—but at the best the guns must for good practice be fired in pairs, for as there is probably a turning moment of, at the least, 4ft. on the 13in. guns, no brake can prevent the turret from jerking out of train if a gun is fired singly. Further, the 8in. guns, though placed in such a position that they tend to balance the turrets, are at such a height above the roller path that the blow downwards and upwards, due to the tilting effects of the fire, will be exceedingly severe. In fact, though up to the present a badly indented roller path or broken roller is almost unknown, we doubt if either roller paths or rollers can be made which would stand the shock produced by simultaneous fire from the four guns at maximum elevation. From a sketch which accompanies the paper, we see that the centre of the 8in. guns above the roller path is about half as long again as the radius of the roller path, so that the blow downwards on the rollers due to the 8in. guns alone would be about equal to three-quarters of the force of recoil supposing the guns were fired vertically; to this must be added the blow from the 13in. guns. The leverage here is about half, and the trunnion being nearly over the front rollers, the blow will be almost entirely downwards on the rear rollers. The maximum pressure in these guns will probably reach about 15 tons per square inch. We leave our readers to estimate what the pressure per square inch of contact of the rollers will be. However, it is not safe to go too far with these calculations from a mere sketch, and we may be overestimating the difficulty. We also notice from the section that the angle of depression for the bigger guns is exceedingly slight, and to meet this they are probably not high above water-line, which experience has shown to be an unsatisfactory position.

By far the most important features in this number of the "Proceedings" are a paper on "Armour for Ships of War," by Professor P. R. Alger, U.S.N., and a part of Assistant Naval Constructor Hobson's reply to the discussion on his paper on the "Disappearing Gun Afloat," which was published in the last number. The conclusions arrived at by both these writers with regard to the distribution of armour run so nearly parallel that they may be advantageously considered together. Professor Alger, after sketching the history of naval armour and the process of manufacture, describes the result of progress in the construction of projectiles and guns, and shows that the attack up to the present has always managed to keep ahead of the protection. He then asks the question, "But if guns now overmatch all practicable armour, and continue to progress as they have in the past, more rapidly than armour, will not they, or even new weapons of offence now unknown, cause the use of armour for ships to be abandoned and become obsolete, as the invention of gunpowder drove out of use armour for men?" There are two arguments in favour of an affirmative reply to this question. The first is based on the "supposed analogy" of ships to men, which is readily disposed of by showing the weakness of the analogy; the second depends on the belief in the advent of a more powerful projectile than any yet known "high explosive shell," so powerful, indeed, that it will destroy armour without actual impact. Professor Alger does not believe that such shells will ever be produced; but even if they are, he points out that armour must be retained for the purpose of excluding projectiles of lesser calibre; and taking an armament of four 13in., four 8in., fourteen 5in. quick, and twenty-six smaller quick-fire guns, he shows that "3in. armour will keep out at least $81\frac{3}{10}$ per cent. of all projectiles, 6in. armour will keep out at least 98 per cent., and 12in. armour will keep out $99\frac{4}{10}$. When we consider the fact that most impacts will not be normal, and that the range will usually be considerable, we may safely say that, under any probable future conditions, armour of about 7in. thickness will keep out 98 per cent. of all projectiles fired against it." The results which the author arrives at are so clearly to the point, that we feel induced to epitomise them here, at the same time commending attention to the paper as it stands. "The following are the principles upon which I believe the armour distribution of battleships should be governed:—(1) The position of the belt should be fixed with reference to the deep-laden draught of the ship, not her light draught. The practice of placing the belt with three-fifths or two-thirds below water at what is called normal draught is bad, because when a ship goes into action she will probably be laden down with extra ammunition, and carry every pound of coal possible. (2) Belt armour should be thick enough to keep out all explosive shell. This will probably require a thickness equal to the calibre of the largest gun brought against it. The new English battleships are to have only 9in. side armour; but I think this is hardly sufficient. Our 13in. common steel shell will carry a bursting charge of 60 lb. through that armour if they hit normally. (3) The heavy guns should be protected normally by turrets, and their supports by barbettes. The armour on both 'should be thick enough to keep out explosive shell, but the turret should, if possible, be thick enough to keep out all projectiles.' Compare this with Mr. Hobson's views given below. (4) Ammunition tubes or other means of protecting ammunition in transit from magazine to turret are worse than useless, except in the case of the heaviest guns, where any damage to the mechanical hoists would put the guns out of action. The danger of a hoist being stopped by indentation of the protecting tube is a grave objection. (5) Heavy conning towers are also worse than useless. The impossibility of getting a commanding view from such a station would certainly prevent the captain of a ship from occupying the conning tower in action." A comparison between two existing American ships and the new battleships is given, which we tabulate here, as it is of considerable interest.

	Indiana. Tons.	Iowa Tons.	New Ships. Tons.
Protective deck	534	562	556
12in. or 13in., and 8in. gun position	1556	1440	1600
Side and bulkhead	1085	1045	1083
Protection to secondary battery	38	39	381
Conning tower and tube ...	55	56	57
Cellulose	55	65	60
Bolts and backing	201	168	235
Total weight of protection ...	3524	3375	3982

Professor Alger, in conclusion of a very able paper, urges the necessity of keeping up the calibre of the guns. "The increase of 1in., from 12in. to 13in., seems small, but it means an actual increase of energy of one-third, and a sight of the results of firing the 12in. and 13in. guns at the same plate would convince anyone of the great value of this increase."

Let us now turn to a section of Mr. Hobson's reply. As regards the protection to be allotted to the guns, that on the turrets and barbettes is most efficient, and should therefore be given most favour, but at the same time, as big guns are practically invulnerable, the protection should as much as possible be kept to the rear end, to protect the loading and breech mechanism, and the crew. On the other hand, medium calibre guns are comparatively vulnerable, and should be more amply protected than is the custom at present.

As regards the protection devoted to the hull, the buoyancy, stability, and uprightness of the vessel have chiefly to be considered, and as these depend imtimately on the "vitals" of the ship, extra weight, or weight saved from the gun protection, should be devoted to making the armour deck powerful enough to resist all shell entering at an angle of 7 deg., and the belt armour must be taken so far down that at maximum roll in which a vessel could be fought, no part of the hull entirely unarmoured should be exposed. But "the effectiveness of armour weight applied to hull protection is not great, the armour being spread over large areas, which form only a fraction of the areas necessary to be armoured to ensure security, and the disposition on these areas not furnishing a high degree of security;" however, "in the case of the hull the demand for armour protection is absolute, but the meeting of this demand can at best be but partial on account of the ineffectiveness of the armour thus employed."

It is satisfactory to know that both these writers speak in high terms of the system of armouring adopted in our own new battleships of the Majestic class. We have considered these two papers at some length, as they are of great importance, and we strongly recommend a careful study of them to such of our readers as are interested in ships of war.

SHORT NOTICES.

Association of Surveyors of H.M.S. Service. Occasional papers. Second series. December, 1895. Brighton: Trill and Sons, 21 and 22, Duke-street. Price 2s.—This part includes, amongst others papers on approximate estimates, cylinder press for bridges and on small gas plants.

How to Cheapen Inland Transit. By J. E. Palmer, Director of the Grand Canal Company of Ireland. Dublin: Hodges, Figgis and Co., Ltd. 1896. Price 3d.—This a reprint of an article from the *New Inland Review*, and its object is to show how valuable for inland transit canals have proved to be, especially in countries, including France, Belgium, and Holland, whose traders compete severely with those of Ireland. The author suggests a clause in the forthcoming Irish Light Railways Bill, making all the Tramway and Light Railway Acts applicable to navigable inland waterways.

The Slide Rule: A practical manual. By Charles N. Pickworth, N.H., Sc. Second edition. Revised. Manchester and London: Emmott and Co., Ltd. Price 2s.—Since the Gravêt or Mannheim slide rule has been introduced into this country, and particularly since the white celluloid faced rule has been made, it has rapidly grown in favour amongst engineers, and although its simpler applications are rapidly learned, the more complex uses require more study and a better knowledge of the principles involved. The mechanical principle is cleverly, because simply, put in this little book, and the reader with moderate patience is led on by easy steps to a comprehension of the whole of the uses of this very convenient form of calculation. As an observer in one of the northern counties of Great Britain once said to a user who was getting ten results of engine power during some brake trials whilst he could get one, "Aye mon, 'ats a grahn bit of stuck." The numerous examples worked out by the author are very valuable as means of learning, and add to the usefulness of what appears to be the best book on the subject.

We have received the first two numbers of *Architecture*, a "monthly magazine of architectural art." They are interesting, abundantly illustrated, and thoroughly well got up.

BOOKS RECEIVED.

Johnson, Ph.D.—*Papers submitted to the American Academy of Political and Social Science.* Issued fortnightly. Philadelphia.—*American Academy of Political and Social Science.* London: P. S. King and Son.

INSTITUTION OF CIVIL ENGINEERS.

SIR BENJAMIN BAKER presided on Tuesday evening at the dinner of the Institution of Civil Engineers, which was held in the Queen's Hall, and at which a very large number of members of the Institution and their guests sat down, including the American Ambassador, the Duke of Teck, Mr. Goschen, M.P., Sir Redvers Buller, Lord Medway, Lord Balfour of Burleigh, Mr. Shaw-Lefevre, M.P., Mr. Bryce, M.P., Sir A. Arnold, Mr. Courtney, M.P., Sir F. Abel, Major-General Sir Charles Wilson, Sir G. Molesworth, Sir E. H. Carbutt, Sir M. Ommanney, General Sir E. Williams, Judge Waddy, General Sir R. Grant, Sir J. Kitson, M.P., Sir M. Fraser, Sir D. Galton, Sir R. Herbert, Sir G. Bruce, Mr. Hayter, Mr. A. J. Barry, Mr. J. W. Barry, Sir Lowthian Bell, Mr. Brunel, Mr. H. Brunlees, Mr. J. Brunlees, Lord Colville of Culross, Professor Dewar, and many others.

The toast of the evening was given by the President, who proposed "The Navy, Army, and Auxiliary Forces," and said that in Sir James Graham's time the difference between danger and safety, as respected the Navy, was represented by a sum of £195,000. In our time a First Lord would indeed be glad if he could make a statement of that kind. Mr. Goschen replied at considerable length, who, among other things, said that whatever improvements were suggested it was the duty of the Admiralty to examine them apart from prejudice or preconceived ideas. One of the leading features of modern naval programmes was the new class, the torpedo boat destroyers. These had been built by English enterprise and English skill, and were considered to have a great success at the Admiralty, and had achieved the astonishing speed of 29 to 30 knots. Such an invention as this was not to be laid up in cotton-wool. On the contrary, the Admiralty thought it their duty to submit this new class of ship to the most stringent test of actual experience, to discover what defects could be detected, and what improvements effected. It was their duty in times of peace to discover what weaknesses existed and to remedy them for times of danger.

As regarded naval construction, the Admiralty were assisted by the genius of the civil engineers; and of one thing he was certain, that after the outbreak of war, if disaster should occur, the First Lord of the Admiralty would be hung by an indignant public, and if he should happen to be that unfortunate individual, when he was in the shades and conveyed across the Styx by the ferryman Charon, he would be hailed by a fellow-passenger, who would be the Minister of the country with which we were at war, and who would be in the same condition as himself, and he would be for the first time able to take sweet counsel with his rival, and deplore with his foreign comrade the result of not having followed the advice of the civil engineers.

Sir R. Buller, Adjutant-General, responded for the Army and Auxiliary Forces.

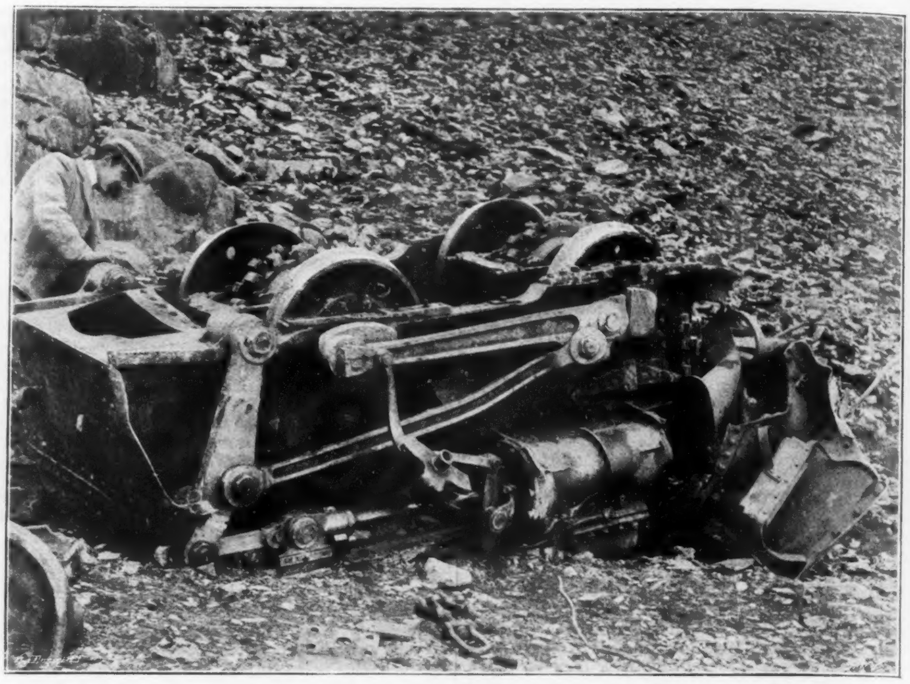
The President proposed "The Houses of Lords and Commons," and observed that Lord Balfour was well known in engineering circles, not only in his work as chairman of the Railway Rates Commission, but on many other occasions, and Mr. Courtney had filled many posts, and filled them all with distinction.

Lord Balfour replied for the House of Lords, and Mr. Courtney for the House of Commons.

The American Ambassador responded to the toast of "Our Guests," proposed by the President.

Mr. Bryce proposed "The Institution," to which Sir Benjamin Baker, the President, made due acknowledgment.

THE DERAILED LOCOMOTIVE, SNOWDON RAILWAY



THE SNOWDON RAILWAY ACCIDENT.

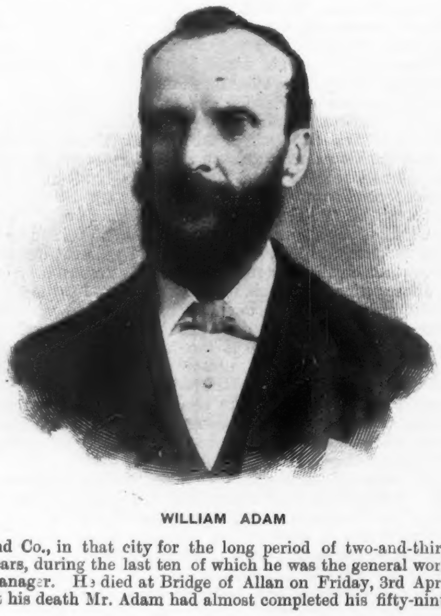
THE above engraving is from a photograph of the mangled locomotive at the bottom of the slope down which it rolled when derailed on the 5th inst., as described in our last impression. It will be seen that the boiler is absent, and that even the framework and heavy motion parts are very much broken. The engine is of small size, of the type much used on the Continent, in which the piston-rod is connected to a rocking lever to which a connecting-rod at a great angle is attached, this rod being connected to a side rod near one end. The wheel base is short and the gauge a narrow one. The coroner's inquiry commenced on Tuesday at Llanberis, and from evidence then given, it would appear that the cause of the accident was a depression of the rails by slight settlement, attributed to thaw of the ground after having been frozen solid. The Board of Trade was represented at the inquiry, at which the engineer of the line, Sir Douglas Fox; Mr. Oswell, resident engineer; and Mr. Aitchison, the manager, and others, were present. Mr. Lloyd Carter appeared for the company, and Mr. Leyland appeared for Messrs. Holme and King, the contractors.

Sir Douglas Fox said that it was not easy to give evidence as to the cause of the accident. There certainly had been a slight subsidence of the permanent way. This depression was one of about 2in., and extended some distance. Five or six of the sleepers had been disturbed, but none fractured. The cutting had been filled with snow, which, no doubt, had frozen hard, but the snow had disappeared when witness visited the place, and that possibly might have softened the ground and caused a depression.

The jury, after deliberating for fifteen minutes, found a verdict that the engine had left the rack, and that the deceased, seeing the engine-driver and stoker leaping from the engine when going at too great a speed, jumped out of the carriage and met his death, but there was no sufficient evidence to show why the engine mounted the rack. Our photograph is by Mr. Symons, of Llanberis.

WILLIAM ADAM.

WE regret to have to announce the death of Mr. William Adam, locomotive engineer, Glasgow, who was connected in various capacities with the works of Messrs. Dubs and Co., in that city for the long period of two-and-thirty years, during the last ten of which he was the general works manager. He died at Bridge of Allan on Friday, 3rd April. At his death Mr. Adam had almost completed his fifty-ninth year, and he had been for so long a period closely identified with locomotive engineers in its "head centre," so far as this country is concerned, that he had become well known in many countries abroad where railways have been established. He was as much esteemed as he was well known.



WILLIAM ADAM

Mr. Adam commenced his apprenticeship under the late Mr. James Reid, who was then the manager of the old Hyde Park Locomotive Works, of Messrs. Neilson and Co., a famous nursery for locomotive engineers of mark; indeed, the deceased was Mr. Reid's first apprentice. Before he completed his time, however, he came under the influence of Mr. Henry Dubs, who eventually became a very notable locomotive engineer. That gentleman was successor to Mr. Reid, who had been induced to take service with Messrs. Sharp, Stewart, and Co., Manchester. Mr. Dubs also became partner with Mr. W. M. Neilson, as well as manager. He had formed a very high opinion of Mr. Adam, who had already earned a reputation.

For a time, however, he was away from the Hyde Park Works seeking professional insight "over the Border." He spent about two years at the Wolverton Locomotive Works of the London and North-Western Railway Company, where he considerably increased his skill as a workman. Returning to Glasgow, he spent about six months in the famous Centre Street Works of Messrs. Randolph, Elder and Co. That was in the early sixties, when the compound marine engines of that firm were getting into very extensive use.

Having now seen something of the world, he was invited to return to the Hyde Park Works—the "new" works at Springburn, in a totally different part of the city, and quite close by two of the leading railways of the Northern kingdom. These works had been designed and laid out by Mr. Dubs, but he did not long remain there, as proposals had been made to him by two or three city capitalists to form a new company, and build new works for the prosecution of the same branch of industry. Mr. Adam had begun to climb the ladder, for he was already an under-foreman. Mr. Dubs began to build his own works on the south side of the city in the year 1864, and he had no difficulty in persuading Mr. Adam to accompany him and become one of his trusted servants, by-and-bye reaching the post of foreman of the fitting-shop. The first engine—one of a small order for the Caledonian Railway Company—left the works on 1st May, 1865; and since then thousands of others have left the same works, many of them for the Colonies, India, and other foreign countries.

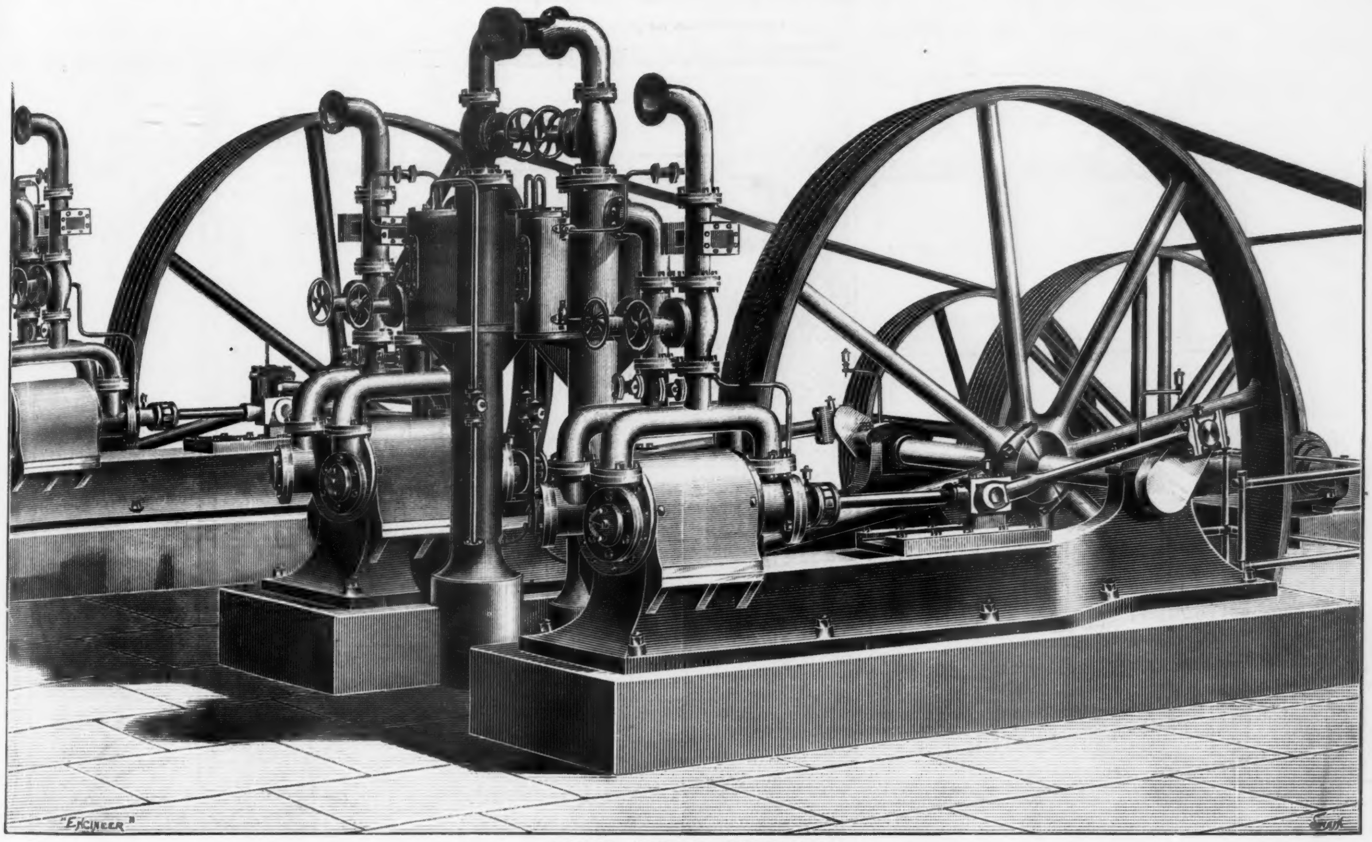
After the death of Mr. Dubs, Mr. Adam continued in the employment of the firm. Ten years ago, almost to a week, he was promoted to the highly responsible position of works' manager, on the death of Mr. Peter Andrew, who was also an able engineer. Mr. Adam knew the works from the very breaking of the ground, and as they became more and more permanently established, and from time to time extended, the army of workmen was greatly increased, but scarcely a single one of them who had been any time within the gates was unknown to him.

Mr. Adam did not set himself up as an inventor, nor did he desire to be regarded in that light; but he thoroughly knew every item in the structure of a locomotive engine. From time to time he made or suggested quite a number of minor improvements in the construction of the finished machine, and he was able to devise numerous ready methods of facilitating work.

His loss will be severely felt by the members of the firm, as also by many of his professional brethren.

SOCIETY OF ARTS.—The Council of the Society of Arts offer the Fothergill prize of £25 and a silver medal for a paper on "The best means of effectually Preventing the Leakage of Current to Earth in Electrical Installations from Generating Heat and Setting Buildings on Fire." The paper should consist of about eight thousand words, and be written with a view to being read and discussed at an ordinary meeting of the Society. Papers submitted for the prize must be sent to the secretary on or before October 1st, 1896. Each paper must be type-written, and bear a motto, the name of the writer being enclosed in a sealed envelope with a similar motto. The judges will be appointed by the Council. The Council reserve the right of withholding the prize or of awarding a smaller prize or smaller prizes, if in the opinion of the judges no essay deserving the full award is sent in.

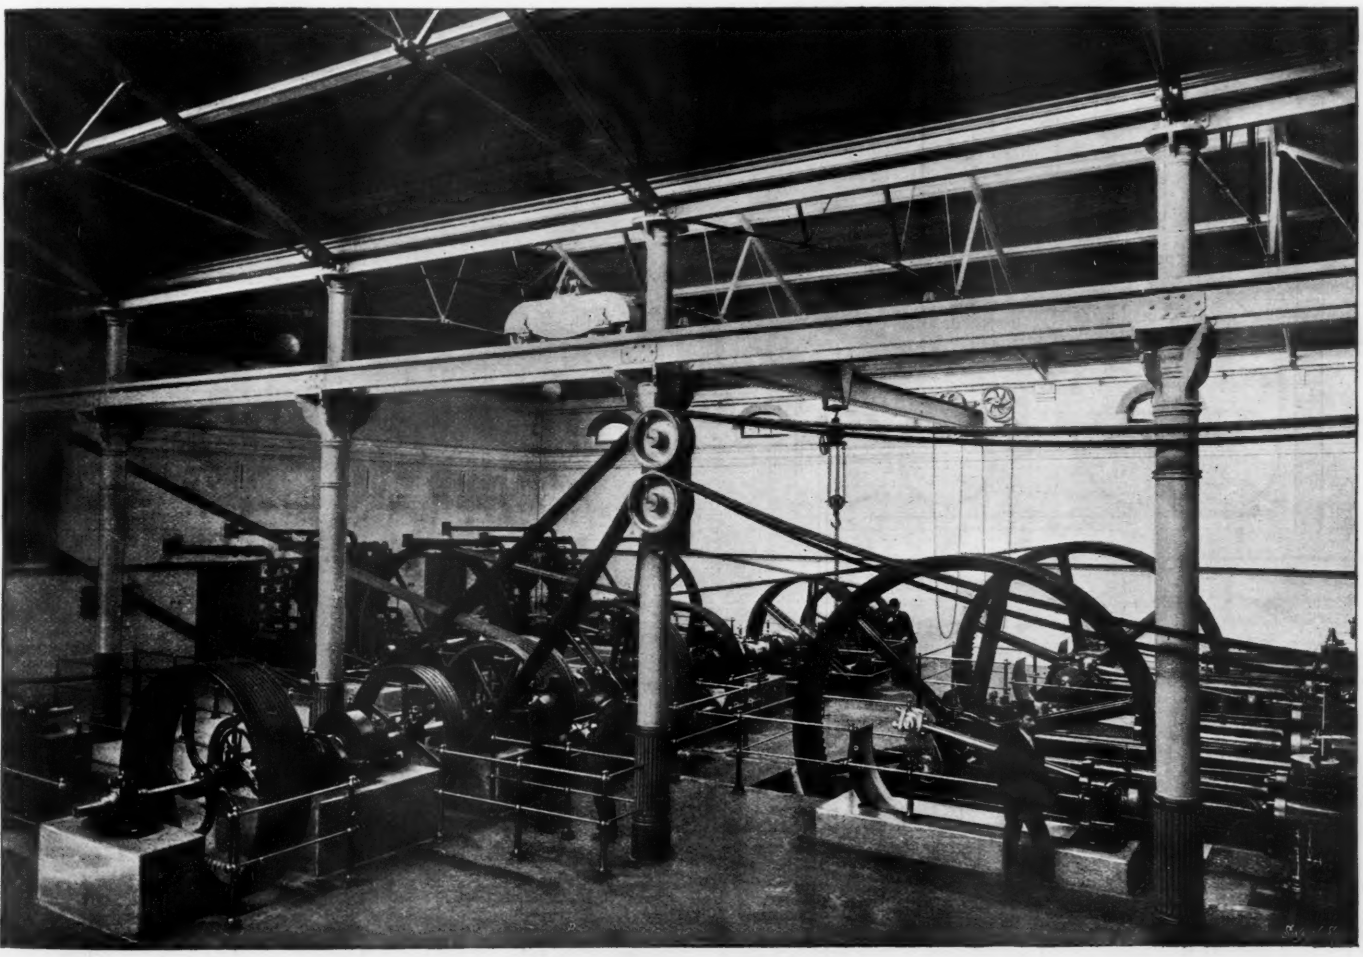
MONSTED'S MARGARINE FACTORY, SOUTHALL



SCHOU'S AMMONIA COMPRESSORS

MONSTED'S MARGARINE FACTORY, SOUTHALL.

On a piece of ground of about sixteen acres in extent near the Great Western Railway, at Southall, Mr. Otto Mönsted has erected a large factory for the conversion of beef suet, milk, and vegetable oil into the now widely-used product known as margarine. The factory only covers a small part of the sixteen acres, perhaps two acres, but the buildings are all large, airy, attractive, and remarkable for cleanness, and the arrangements adopted for securing the absolute purity of the product. A visit to the works removes any doubts any one might have as to the desirableness of margarine as a food, and convinces one that as made in a factory like this it is far preferable to the butter made in small insanitary dairies, where the work is done with hands, where the milk stands in an atmosphere not too innocent of farmyard effluvia, and where contamination is as easy as uniformity in the product is difficult. Margarine cannot take the place of butter of the best kinds made in large, well-appointed dairies, but it is infinitely preferable and superior to the cheap butters for cooking purposes, and is better, though not so readily accepted, for table purposes. Since, however, the manufacture of margarine has ceased to be a mystery, and it has been sold under its own name, the sentimental objections to it have rapidly faded, and prejudice founded on ignorance has disappeared.



VIEW IN THE LARGE MACHINERY HALL

The Southall factory has been carried out from designs which are probably the most elaborate adopted for any industrial buildings in England. The offices and the accommodation for the workpeople are on a scale which is lavish in every respect that relates to light, air, cleanliness, and ample ornament. The architecture and ornament, and the provisions for comfort and scrupulous cleanliness in every

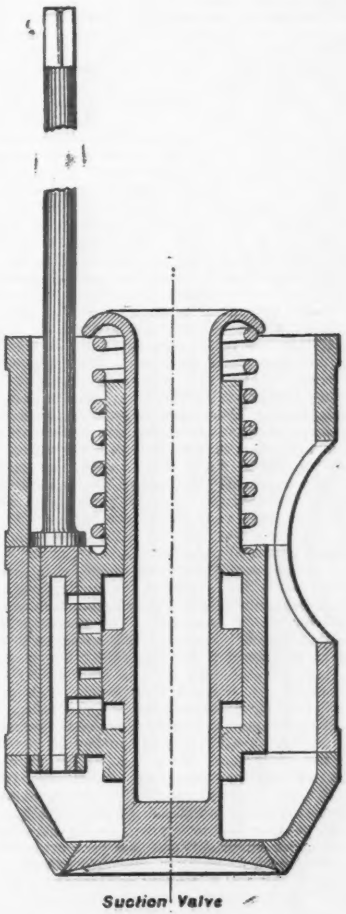
Discharge Valve



Suction Valve

department, inspire the workpeople with a feeling of pride and of dignity in their work and the works.

The raw materials are, firstly, beef suet, which is received in large barrels from Birkenhead and Deptford and from the great stockyards in America and elsewhere. It is beef suet in a splendid condition, all the insoluble stearine having been pressed out of it. In this condition it is known as oleomargarine. The second ingredient is sweetnut oil, and the third milk. The milk is taken from the dairy farmers of the district, and when in full working order this factory will be able to take and deal with 30,000 gallons a week. On entering the factory the receiving rooms for the milk, where about 5000 gallons per day are now dealt with, are first seen. Here the milk, passing through the receiving tanks, travels by gravitation into ripening tanks below, which are arranged on the Danish process, and from thence by centrifugal pumps it is sent into the churns above.

From this milk store the visitor passes to the stores of the two other products—the oleomargarine, and the sweetnut oil. Both these are stored in casks in warehouses, in which a regular temperature is maintained. From both these stores, the visitor may follow by one of the lifts the barrels of oleomargarine and of nut oil, and see them opened. Most of the beef suet is of a rich yellow and minus its stearine. It is broken up into convenient pieces, and then turned into one of sixteen large vats, capable of dealing with about fifty tons of oleomargarine at once. These vats are steam jacketted. After melting, the liquid fat is conveyed through pipes at the bottom of the vat to meet the milk at the churns below. The vegetable oil is simply pumped from the tanks, into which it is emptied from the barrels, into the churns with the oleomargarine and milk. In the churnery are nine churns, driven by steam power, and jacketed with steam and hot water to keep the contents at a proper temperature during the process of churning. These nine churns are capable of turning out about fifty tons of margarine a day.

From the churns the bubbling, yellow, warm margarine runs down a wooden shoot, where it is met by a disintegrating and ice cold jet of water, the width of the trough, and by it driven into a cooling tank below. This is built of white glazed bricks, and presents a spacious surface for the heated fat globules to crystallise upon. They spread themselves over an area of 30ft. by 20ft. of ice water until they have quite solidified. There are four of these cooling tanks in this building, and as they stand side by side they present a very pretty and curious appearance, and are entirely overlooked from the churn platform at the end of the hall, which covers about an acre.

When properly cooled, the margarine, in crystals resembling butter granules, are collected with long handled wooden tools, and placed in piles on wooden wagons, where for two hours draining goes on, so that the water may run off, after which these piles are taken to the huge circular working tables, like large fluted conical roller butter workers, of which there are four in the hall. There the margarine is slowly milled together, so that all the particles are combined into solid masses. During this process the margarine is "salted to taste."

From here, on other machines, the margarine is submitted to a finer and more complete working process, so as to produce a more regular and perfect texture, after which it is ready to be moulded into lumps, pats, rolls, or any shape demanded by each of the many markets to which Mr. Monsted's manufactures go. From the time we saw the raw products in the stores or the churn rooms until they had been weighed up and packed as the finished article, they had not been touched once by the human hand. The raw materials are weighed into the churns and the weight automatically recorded.

Turning now to the refrigerating pumping machinery and to the motive power for dealing with all the machinery, the engines will be found illustrated in The Engineer of the 14th of February last. In the boiler house are three Lancashire boilers, made by Tinker's, Hyde, Manchester, each 30ft. long and 8ft. in diameter, with a steam pressure of 120 lb. Each boiler has two flues 3ft. 3in. diameter, tapering to 2ft. 9in. One of Calvert's circulating economisers is placed in the position shown in the engraving, page 404. The coal is led in upon a miniature railway and tipped into hoppers after each load has been automatically weighed and registered. Water supply is obtained from thirty-two Abyssinian wells, probably the most extensive nest of this description of wells in this country. These are all connected, the pipes being brought into the pumping room, and through them 10,000 gallons of water an hour can be elevated by the powerful pumps into the tanks in the water tower at the top of the main building.

The engine and machinery hall covers an area of 7200 square feet, and is 31ft. high, with a lantern roof that gives it a very light and airy appearance. A view of part of this hall is given on page 403. On the floor there are the two compound condensing engines, fitted with Collman's patent valve gear, made by J. Jessop and Son, Leicester, as recently described by us. In the same hall are four ammonia compressors, which form a part of the refrigating plant constructed under the patents of Mr. P. Schou, and used for cooling the water from its natural temperature down almost to freezing point. This plant is of the 150 tons capacity, and the compressors, made by Messrs. Tuxen and Hammerich, are shown by the engraving on pages 403 and 405. In the same hall is the electric plant, which is driven from the large steam engines. This plant consists of four dynamos, the one being used for charging the accumulators only. The total capacity of this installation is 800 ampères working with 110 volts, representing an illuminating power equal to 26,000 candles. The accumulators are capable of lighting a part of the factory for six hours. The plant was made by Messrs. Calvert and Co., of Manchester. The whole of this engine hall plant is arranged in duplicate, so that repairs can be effected without stopping the work, and the repairing is facilitated by a travelling crane with gear which runs over the whole room.

The compressors are of the horizontal double-acting type, with a compression cylinder, $10\frac{5}{8}$in. diameter, $21\frac{1}{4}$in. stroke, running at 65 revolutions per minute. The cylinders are fitted with one suction and one discharge valve at each end, as shown by the general and sectional views on page 405, the cover being concave on the insides, to give more room for the valves. The valves are the most important part of an ammonia compression machine, and they are a special feature of Mr. Schou's machine. He claims for them that the troubles inherent to compression cylinder valves have been practically eliminated by them. The chief troubles with ordinary valves arise from the fact that there is no means of regulating the velocity or force with which they strike against the seats when closing, the result being that in a comparatively short time, they hammer and destroy themselves and their seats and become leaky. In the valves designed by Mr. Schou an air cushion device is attached to the valve spindle of each valve, by means of which the velocity and force of closing may be regulated at will by the simple manipulation of a stop cock, the spindle of which is carried through the valve chest to the outside, and so may be regulated by the attendant at will, while the machine is working. This is shown by the valve sections on page 405. The effect of this has been great durability of the valves, some of which have been used with this appliance for a number of years, without any repairs or apparent signs of wear, and they are still as tight and as efficient in their action as when first started. The number of parts has been reduced so as to eliminate any screwed connections which are apt to work loose and interfere with the action of the valves. As in this system the gas is never heated above its saturation point, and as consequently the compressor has only to deal with humid or saturated gas, no water jacket is necessary or is used. An important point in this compressor is the small amount of clearance required, not more than $\frac{3}{64}$in. being allowed at each end of the stroke. This clearance is maintained by a special arrangement of crosshead, by means of which any alteration due to wear of the moving parts to this clearance can be seen outside the cylinder, and can be at once allowed for at the crosshead. The clearance being so small no oil is required to take up this space, only such oil being used as is necessary for lubricating the piston, &c. This is a feature which also adds to the efficiency of the compressor, as in Mr. Schou's view the use of large quantities of oil to take up clearance space is undesirable, because the oil absorbs the vapour of ammonia during the compression stroke, and gives it up again during the suction stroke, thus preventing the compressor from drawing in during that stroke as large a weight of vapour as it would otherwise have done had the oil not been used. To prevent leakage of ammonia vapour passing the piston-rod stuffing-box, a specially designed packing box is applied, which fits closely to the rod, the space between these two compartments being charged with oil from an oil filter, described hereafter. This oil chamber acts as a seal to prevent any leakage of ammonia at this point. At each back stroke a certain amount of this oil escapes past the composition rings into the cylinder, and a specially made apparatus, called an oil separator, is supplied for separating the oil from the ammonia.

The oil separator is an apparatus consisting of a large chamber, through which the compressed ammonia is passed on its way to the condenser. The passage of ammonia through this vessel takes place at a comparatively slow speed, and the oil has time to gravitate to the lower part of the vessel, from which it is forced into the oil filter, which is placed above the piston-rod gland. A certain amount of gas is necessarily carried over with the oil, and this gas is drawn away by means of a pipe connecting the top of the oil filter to the suction pipe of the compression cylinder. The oil, after being filtered and cleansed, is used over again in the oil chamber in the piston-rod gland, as above described. The total consumption of oil for this purpose in the compressor does not exceed two gallons in four weeks. The manipulation of the oil separator is exceedingly simple, as the only duty required of the attendant is to regulate the opening of two simple cocks. There are two filters, as described above, fitted to each machine, so that one may be used while the other is let off for cleaning purposes, and this is an important feature of the system, as it avoids all necessity for stoppage. The position of these oil separators is shown on stands at the side of the cylinders in the end elevation and plan, page 405. The refrigerator of each set consists of a circular wrought iron cistern—see page 404, containing a series of coils of lap-welded pipes, $1\frac{1}{4}$in. diameter inside, tested to a pressure of 2000 lb. per square inch. The total length of this piping is 3300ft., or equal to a cooling surface of 1300 square feet. This is made up of six coils of equal lengths, each coil consisting of one complete pipe; these coils are arranged spirally, one inside the other, and are connected together at the ends by suitable couplings, in such a way that any one length may be taken out at will. As is well known, these pipes are apt to become rapidly corroded above and just about the water level, and to prevent this corrosion the pipes are covered above the water-line and to 6in. below with lead. For keeping the water in the tank in circulation an agitator revolving on a spindle in the centre of the tank, and driven by means of a small countershaft placed at the top of the tank, which in turn receives its motion from the line shaft, as shown in the vertical section, page 404, which also gives a section of the large underground tank used in connection with these refrigerators. The two ammonia condensers are placed on the top of the roof, one for each pair of compressors. They are constructed on the surface evaporation system, with the object of reducing the amount of condensing water required to a minimum. With this arrangement a saving of 90 per cent. of water is obtained, compared with the water required in an ordinary submerged condenser. The water is used over and over again, and is circulated by means of centrifugal pumps. Each condenser consists of five sets of $1\frac{1}{4}$in. lap welded coils, tested to a pressure of 2000 lb. per square inch, arranged in such a way that one or more sets can be cleaned while the machine is working. A special feature in the construction of this condenser is the few joints used for connecting the coils. The ammonia vapour enters at the top of the condenser, leaving it at the bottom, after being condensed. It is then led into an apparatus called a recipient, through a pipe entering at the top of the recipient, and terminating near the bottom. Another pipe also leads from the bottom of this vessel, then carries the ammonia forward to the top of the refrigerator, passing through a regulating valve on the way. The object of the recipient is to prevent any vapour which may possibly leave the condenser without being condensed from entering the refrigerator, and it also extracts any foreign matter which may pass through the condenser with the ammonia.

The ammonia condensers above referred to we shall illustrate in another impression.

The shafting shown at the foot of page 404 is particularly worthy of attention. It is desirable that alternative sets of machinery should be put to work as required, and that the pulleys by which they are driven should not be running as loose pulleys on bushes when not driving the machinery, as is usually the case. To achieve this, the hollow shafting made by the Eisenwerk Wülfel, of Hannover, is used. In this, as shown at page 404, the main line of ordinary shafting is carried by bearings in the ordinary way, but between these bearings it is enclosed by hollow shafts running on separate bearings and carrying the outer part of the clutch necessary for connecting the two shafts, the inner part of the clutch being on the solid central shaft. In this way any of the machinery driven by the pulleys on the hollow shafts can be stopped, and the pulleys themselves also stop, no pulleys running either on bushes or on shafts running uselessly in bearings. The arrangement illustrated works exceedingly well, and avoids much of the trouble with ordinary clutches and loose pulleys. Various forms of this shafting and connecting gearing are made by the Eisenwerk Wülfel.

(To be continued.)

PROVISIONAL ORDERS, 1896.

It will be necessary to give a brief retrospective glance in connection with our article on "Private Bills" for the present session in a recent impression, before proceeding to consider the Provisional Orders now in progress through Parliament. In the first place, one Royal Assent has been given, and it is to the Metropolitan District Railway (Extension of Time). Probably the fact of its being a "suspended" Bill from last session may account for it becoming an Act at so early a stage. Eight or nine other Bills, some of which are fortunately entitled to rank as "unopposed," have passed the third reading; but necessarily as yet not much progress can be expected. Three tramway Bills, it is much to be regretted, have of their free will been erased from the roll-call—that is, withdrawn. They are, one promoted by the Corporation of the northern granite city, another under the title of the Cork Junction Tramways, and the third hailing from Derby and Ashbourne. The first of these may be disregarded, as it proposes to construct nothing, but to borrow money, the amount of which is not stated. The secession of the other two deserves a word of notice, since the mileage of both amounted to over twelve miles, and the capital asked for reached the fair total of £240,000. It is not quite apparent, even allowing for cost of buildings and equipment for electrical or other modes of traction, how or why 12·48 miles of tramway should cost this large sum. If tramways which have not to purchase any land to lay down their track, and build no stations, run to this figure per mile, it might be fairly asked, what about the price of light railways, which have to incur an expenditure on both these items? Of the eight London Water Transfer Bills two have been withdrawn, and the other six classified as those belonging to the list of "Second reading negatived."

In passing on to the "Provisional Orders," there is no tramway project of any particular importance, if we except that asked for by the Corporation of Hull, who propose to spend £300,000 in laying down new lines, and an additional sum of £15,000 for buildings and equipment in the borough, town, and county of Kingston-upon-Hull. About half a million is the total capital required by the fifteen Tramway Provisional Orders sought for in England, Scotland, and Wales, which, as the total mileage is fifty miles, allows £10,000 per mile for the carrying out of the work. It would appear that whether it is a question of a "Bill" or a "Provisional Order," there is not much difference so far as the capital required is concerned. With regard to the Gas and Water Orders, there is nothing worth chronicling, but there is something to be said respecting those pertaining to electric lighting. It is not that the number applied for is particularly large, being but thirty-eight for England, Ireland, and Wales, nor the capital excessive, not surpassing one and a quarter millions, but it is the wide range which this method of lighting is gradually embracing, which distinguishes its advancing career. Comparatively small places, such, for instance, as Ambleside and Keswick, ask for a modest few thousands to light their respective districts with the *fin de siècle* illuminant. It is noticeable that Scotland appears to make no sign in this respect this session. Foremost in this especial category is to be found the Liverpool Electric Lighting Order for a supply to the whole city, with a proposed expenditure of nearly one-third of the total capital of the whole list. Bath comes next with £120,000, and Manchester with £100,000. Ireland is by no means behind, as Dublin, Cork, and Queenstown are good for £100,000 in the aggregate. It has long been a reproach, and in some measure deservedly so, to not only ourselves, but to our continental neighbours also, that we have not availed ourselves of the great motive power which for ages, so to speak, has laid dormant and in abeyance, although always existent, in our natural water supplies. These have always been used for purposes of irrigation on a small scale, but on a much larger scale for those of navigation in the form of canals and canalised parts of navigable rivers. It has remained for electricity in the more advanced stage to develope the utilisation of this important physical motor in the production of the electric light.

In mountainous regions there is always a certain amount of apparently hidden power to be obtained from even a very small cataract or fall of water, the immediate effect or productive action of which is not restricted to simply the near vicinity of the motive force. In this respect water has an advantage over steam, which with all preventive precaution cannot be taken beyond a very reasonable distance, even in tropical climates, from its generative source—that is, the boiler, if its pressure, which is equivalent to the power developed, is to be maintained constant. Regarded from this point of view, electricity has no compeer. Distance, so far as mere transmission of current is concerned, is nothing. A telegraphic message, if the "line be clear," can be sent from Downing-street to Calcutta and the answer returned in less than three minutes. It may be noticed that, in its application for a Provisional Order, the London United Tramways propose to empower the Company to place posts and wires in or over streets and roads in the County of London for purposes of traction by electrical or mechanical power. Although the trolley or overhead mode of transmission has been inaugurated in England, yet so far as London is concerned, this is quite a novel departure.

CATALOGUES.

Since our last acknowledgement we have received the following catalogues.

R. Hunt and Co., Earles Colne, Essex. Shafting, Couplings, Collars, Plummer Blocks, and Cast Iron Pulleys.—A printed and well-illustrated catalogue of fittings, including the swivel bearings, with very large proportions of length to diameter, and the makers muff coupling.

The London Emery Works Company, 10 and 12, Vine-street, London.—An exhaustive catalogue of polishing and grinding machinery, and one which shows the large part now played by emery wheels, not only in grinding tools, but in finishing and giving minute accuracy to work, such as parts of steam engines and machinery not obtainable otherwise. This catalogue contains 169 pages, and there is an illustration of a different machine on a large part of the whole of these, these machines including many forms of simple grinders, cutter grinders, polishing machines, shaping machines, finishing, and truing lathes and roller lathes. With the catalogue are some samples of emery and glass cloth, of which the company manufacture on a large scale with special plant. The name is not as it should be on the back.

Bennett and Sayer, Engineers, Derby. Brick Machines, Crushing Mills, Pug Mills, Roller Mill Brick Machines, Plastic Brick Plant, Presses, Brickyard Railways, and Endless Chain Tramways, Mixers, Dies, and Cutting Tables.

C. A. Zadig and Co., 11, Queen Victoria-street, London.—Tipping Wagon, Portable and Permanent Railway Gear, Wheels, Axles, Bearings, Turntables, and Double and Single Bogie Wagons.

The Butterley Company, Limited, Butterley.—A handy little pocket list of the dimensions of Iron and Steel Bars, Angles, Sheets, Buckled Plate, and other Bridge Floors.

John and Henry Gwynne, 89, Cannon-street, London, E.C.—Centrifugal Salvage Machinery, with illustrations of some of the vessels recovered by salvage companies employing Gwynne's invincible pumps; the floating of H.M.S. Sultan and of the s.s. Utopia being feats of which the firm is deservedly proud.

J. H. Wilson and Co., Limited, Sandhills, Liverpool.—Lifting Machinery, including cranes large and small, jib and derrick, steam and hydraulic, and excavating, grabs, winches, Carey's concrete mixer, and Duckham's and Denison's weighing machines.

Southgate Engineering Company, Limited, New Southgate.—A catalogue in four parts, all well illustrated. No. 1 of Cranes, No. 2 of Machine Tools, No. 3 of Steam Pile Drivers, No. 4 Coalwashing and Briquette Machinery.

C. Cadle, Dublin.—Catalogue of Duplex Jet Water-wheels of the hurdy-gurdy type, but with double buckets in pairs on either side of the disc carrying them, and fed by a double nozzle mounted on a spherical joint, which is raised or lowered by a governor, which puts the jets into the best or a less efficient position, the water remaining constant except as controlled by a hand sluice.

A. G. Mumford, Colchester.—A large well-illustrated catalogue of Marine Engines, Duplex and Vertical and Horizontal Donkey Pumps for feeding Boilers, and large Direct-acting Duplex Pumps for Waterworks. The catalogue also contains a number of special designs of ship machinery, including ash hoists, winches, valves, fan and fan engines, and launch and other boilers.

Robinson and Auden, Limited, Wantage.—A new catalogue of this firm's Steam Engines, Boilers, Thrashing Machinery, Fixed and Semi-fixed Engines, High-speed Vertical Engines, Power Chaff Cutters, and other machinery.

Sharp and Kent, engineers' and contractors, 34, Victoria-street, Westminster.—Electrical Fittings, Materials, and Machines.

Tangyes, Limited, Birmingham.—A new catalogue and revised lists and prices for the 1891 catalogue, containing Wall and other Cranes, Pulley Blocks, Ship and other Jacks and Pumps, Governors, Pump Fittings, Boiler Fittings.

John Spencer, Globe Tube Works, Wednesbury.—A new and revised edition, comprising Iron and Steel Tubes and all kinds of Fittings, Short Lengths, Valves, Pipe, Fitters' Tools, Iron Sewer Pipes, and Taper Ventilating Pipes.

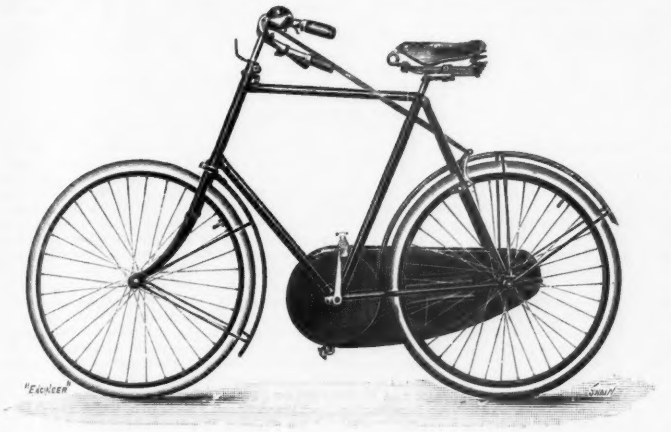
Johnson and Phillips, London.—An illustrated catalogue of Cable Making and Wire Covering, Sheathing, and Measuring Machinery. Well printed, with illustrations taken from photographs of the actual machines, many of which are of novel design. The catalogue has the name on the back, so that it may be easily found.

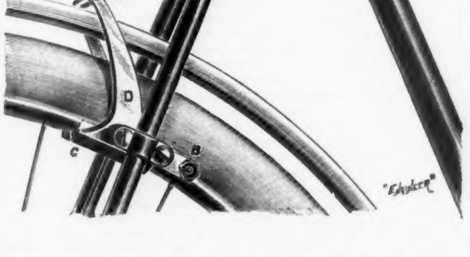
Professor Seeley, F.R.S., will begin the summer course of lecture-excursions with the London Geological Field Class at the end of April. The subject of the series will be "The Physical Geography and Geology of the Thames and its Tributaries. This is the eleventh annual course." Mr. R. H. Bentley, 31, Adolphus-road, South Hornsey, N., is the hon. secretary to the society.

HUDSON'S REAR-ACTING CYCLE BRAKE.

The objections to brakes acting on pneumatic tires, more especially of the lighter forms, are well known to cycle users and tire makers, and the objection to the application of the brake to the light front wheel in the fork is also well understood. The brake illustrated has been made to overcome these objections, and trials of it have proved its value as a powerful brake applied where it can do no harm to the tire, and give rise to no danger of buckling either the front wheel or the forks, whilst it secures certainty of action and safety so far as a trustworthy brake can obtain it.

The engravings show the brake as applied to a machine, the brake handle being altered to lie and work in front of the handle bar, and in the plane of the steel rod or wire partly rubber covered, by which the brake handle is connected to the brake proper. The brake itself is shown by the enlarged view of the upper part of the rear or driving wheel, on the rim of which it acts. Clips of suitable form attached to the vertical members of the frame hold the pivots B of the pair of bent levers D, the lower parts of which carry at C a leather or india-rubber pad, which bears upon the rim at an angle of about 45 deg. To the upper ends of the bent levers D the wire A is attached and led to the brake handle similar to an ordinary brake handle on the handle bar. After several months' severe use the wear on the rim is found inappreciable, and apparently limited to polishing the bead or roll. It took a long time to remove the enamel, and with rubber in place of leather there is no doubt the wear would be inappreciable in many years. It is claimed for this brake that firstly it is trustworthy, owing to its directness and simplicity, that it visits no strain on forks, does not damage the tires, that its efficiency does not depend on the tire being inflated, that it puts no strain on the spokes, such as occurs with a band brake, that it is unaffected by mud in the dirtiest weather, and that it is extremely powerful, one finger on the lever being sufficient for all ordinary purposes, while the wheel is readily skidded with two. The machine shown, it may be mentioned, is one to which Mr. J. G. Hudson, of Bromley Cross, Bolton, had large chain wheels fitted for experimental reasons, and he has found within the limits of ordinary pressure on the pedals the friction of the machine is only 1 per cent., thus confirming the figures we mentioned some time ago when remarking that certain friction-reducing devices were based on a fallacy, or worse.





THE ACCELERATION OF RAILWAY SPEEDS.

The question is frequently asked as to how fast a passenger train can be run. The various conditions which affect the making of railroad records are intimately correlated, some being found in the engine, some in the train, and some in the roadbed and track upon which they run. Taking the standard fast train of to-day as represented by the Empire State Express on the N. Y. C. and H. R. R. R., it can safely be said that when in 1893 it ran for a short distance at over 100 miles an hour, it was for that short spurt travelling up to the very limit of the possibilities of our present system of railway locomotion. The whole tendency of the age toward time saving makes it certain that, before the twentieth century is far advanced, the travelling public will be clamouring for a vastly increased rate of speed over present rates. The experience of the past teaches that when the patrons of a wealthy transportation company, whether on sea or land, demand a faster service—and are willing to pay for it—they usually get it. We state a few suggestions as to the proper lines of investigation to be pursued in order to effect such improvements.

The track.—This must be straightened as much as possible. On a tangent the whole tractive effort of the engine is available on the drawbar of the train. On a curve the effort is split into two components, one of which is expended against the outer rail of the curve, while the other is available to haul the train. The component, which is lost in the outer rail, increases with the increase of the sharpness of the curve; and *vice versâ*, the more we can straighten out or "ease" the curve, the less will be the loss from this cause.

Grade must be lightened.—The resistance due to grade is too obvious to call for elaboration here.

Heavier rails must be provided.—No amount of care can keep a roadbed in perfect level. The storms and frost of winter and the drought of summer will develope soft places. If the steel rail be deep and heavy, it will bridge these weak spots, and preserve the general level. The load of the train is concentrated at certain points of contact, where the steel tire meets the steel rail. The ideal track will distribute this concentrated load as evenly as possible to the widest possible surface of roadbed. For a speed of 75 miles an hour, 100 lb. to 125 lb. rail should be laid upon ties 6in. by 10in. by 10ft. long.

Better rail joints will be required.—The joints are to-day by far the weakest point, even in our best tracks. The perfect joint should be as rigid, and yet as elastic, as the rail itself. To get the required depth for stiffness it should be of the sub-rail type, associated with some form of angle bar to secure alignment. With the introduction of 60ft. rails, the number of joints will be reduced to one-half, and some of the expense thus saved could be well spent in improving their quality. Whenever it is possible to hear the "click" or "hammer" of a joint, we may be sure that a certain amount of the momentum of the train is being absorbed at that point. A perfect track involves a silent joint.

Engines.—The fast express engine of the future will be a single driver. It has been abundantly proved that 20 tons on one pair of drivers will give all the adhesion necessary to haul an express train of to-day. Engines with single drivers are not troubled with slipping of wheels, except occasionally in damp weather. At such a time steam sanding apparatus gives the drivers the necessary adhesion. Where the loads are heavy, as in the slower and heavier passenger trains or in freight trains, it becomes necessary to couple on an extra pair of wheels. The Philadelphia and Reading engine is doing better work with a single driver than its sister engines of the four-coupled type. The single driver engine is easy to counterbalance and the internal friction is largely reduced. The drivers will not be of less than 7ft. or 8ft. diameter, and running as they will on 100 lb. to 125 lb. rail they can be safely loaded up to 25 tons. This will give sufficient adhesion for 20in. or 21in.-cylinders, which, with a steam pressure of 200 lb. to 225 lb. and large steam ports, would give us a locomotive of very large high-speed hauling capacity.

Cars.—It is in the reconstruction of cars that the greatest gain will be made. We have for many years been of the opinion that the weight of a Pullman car was out of all proportion to the number of people it carried. In the train made up of Pullman cars, the engine has to haul not less than 1½ tons of dead load for each passenger carried. On the race track the bicycle carries its load at average railroad speed on a deadweight basis of 20 lb. to the passenger. One hundred and fifty times as much deadweight to be carried per passenger on a railroad as on a bicycle. Making all allowance for the shelter and convenience of car travel, there is evidently something wrong. The weight of the car is excessive, and it is the outcome of the rough and dangerous condition of the earlier railroads, and of the competition among the builders to excel in providing a luxurious "palace" car. The car was made heavy in order that it might ride easily on rough track and hold together when it jumped the track; it was loaded down with heavy plate mirrors, solid hard wood carving and moulding, and massive brass and plated work in the attempt to beautify it. The two causes have both disappeared. Our trains stay on the track and automatic signalling has done away with collisions. They can safely be built lighter. A better taste has been cultivated among us in the matter of decorations and fittings, and Pullman cars could be relieved of much silver plating and glass plate, and yet be made artistic and pleasing in their interior fittings.

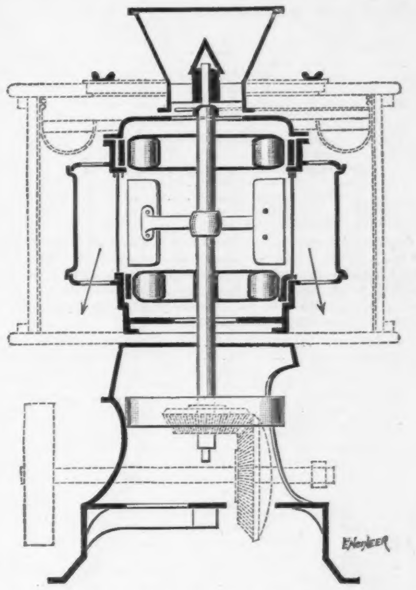
The weight per linear foot of an express train could be greatly reduced by reducing the length of the individual cars. A car rests upon its two trucks in the same way as a bridge upon its abutments. Like the bridge, its weight per foot will increase rapidly with its length. Two 40ft. cars would not weigh as much as one 80ft. car; and though there would be four trucks for two, they would be of very much lighter construction. Moreover, the distribution of the load upon double the number of trucks would cause it to haul with greater ease. The trucks of a 50-ton Pullman car depress the track by their excessive concentration of load, and are always running in a hollow or, as it has been well expressed, "climbing up hill." The cars could be further lightened in their construction by the substitution of high grade steel for timber. The use of nickel steel for the floors and side trusses, with thin plating for sides and roof, would result in a light but very stiff and strong car. By furnishing the interior with rattan or basket work chairs and lounges, such as are to be found on some lines to-day, a further saving of weight could be effected. It is a mistake to claim that light cars ride roughly. On rough track they do; but on first-class track weight ceases to be at a premium.—*Scientific American.*

THE PROPFE MILL FOR GRINDING COAL DUST FUEL.*

One of the chief drawbacks to the extension of the use of coal dust fuel is the difficulty of procuring a sufficient supply of the comminuted material in a homogeneous condition. This is owing to the class of mill—centrifugal disintegrators—hitherto employed for grinding the coal. These mostly depend for their efficiency on the impact of the lumps of coal against a number of spikes or pins mounted on a frame rotated at high speed, but as the force of the impact and its effect on the material are dependent on the specific gravity and brittleness of the latter, the results obtained with coal are less satisfactory than with any other substances exhibiting more suitable structure. Another point, too, is that the excessive speed at which the mills must be run, in order to obtain sufficient force for pulverising the coal, both necessitates more substantial and costly construction, and gives rise to rapid currents of air which allow the material to become overheated. Again, notwithstanding the use of safety appliances, the risk of damage to the apparatus from extraneous substances, fragments of iron, &c., at such high speeds is considerable, and the repairs bill consequently heavy. On the other hand, ball mills are of too insignificant capacity to supply the demand, on account of their relatively small available grinding surface, and diminished effect due to injurious friction.

The Propfe mill has been designed to obviate the defects and combine the advantages possessed by mills of both the classes just referred to. The ideas embodied in its construction are:—A rotating frame affixed to a vertical spindle, and surrounded by a ring of great strength, carries at its periphery a series of vertical rollers so arranged that their pressure against the grinding surface of the outer ring increases, by centrifugal force, with the speed at which the apparatus is worked, and *vice versâ*. This will admit of irregular-sized lumps being fed to the mill, and will remedy the defect alluded to in ball mills, viz., the small amount of utilisable surface, by the substitution of centrifugal pressure for that of gravity. The employment of these rollers also allows of greatly reduced speed as compared with the ordinary disintegrator, since here the comminution is effected by pressure between two metal surfaces instead of by the force of the coal itself; in fact, the rate of peripheral rotation is between one-seventh and one-twelfth that of ordinary disintegrators.

The annexed figure will assist in the comprehension of the verbal description. It will be seen that there are two sets of rollers, one at the top and the other at the base of the milling chamber, the latter set being for the purpose of grinding down any portions left by the upper rollers in too coarse a condition to pass through the sieves constituting the inner walls of the apparatus. In the central space between the two sets of rollers the ground coal is exposed to a current of air induced by a number of vanes mounted on a main axle, and is thereby forced through the sieves into the outer annular space for collection and removal. The feed-hopper is fitted with a rotating arm to assist the descent of the coal on to the roller frame, centrifugal force then directing it to the space between the rollers and the ring. An automatic valve prevents the mill getting stopped up, and the whole is enclosed in a wooden cover lined with sheet metal. The power is applied by belting to the pulley at the lower extremity of the axle, but, for large sizes, bevelled gearing, as suggested by the dotted lines in the figure, is preferable.



The efficiency of a 12 to 18-horse power mill of this description—costing about £190—is:—Delivery, per hour, hard coal, 20 to 50 cwt.; delivery, per hour, brown coal, 15 to 45 cwt.; working at 200 revolutions per minute. The cost of grinding is estimated at about 1s. 3d. to 1s. 6d. per ton, producing a dust that will all pass through a sieve containing 900 meshes per square centimetre. Recent tests made with this mill at the Anhalt Colliery, at Frose, showed that with 17·1-horse power—about 4·5 of which may be taken as necessary for driving the subsidiary machinery, elevator, &c.—30 cwt. of coal dust were produced in the hour, or about 2½ cwt. per horse-power per hour.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Heavy rails.—In view of the recent discussion as to rail sections, it may be of interest to give here the dimensions of the 90 lb. rail of the Lehigh Valley Railroad, representative of the clumsy, large-headed type, as compared with the 90 lb. section recommended by the rail committee of the American Society of Civil Engineers, the latter being representative of the stiff, well-designed rail, specially designed for a good distribution of the metal and a thorough rolling of the metal at a uniform low temperature:—

	L. V. R. R. In.	Am. Soc. C.E. In.
Height	5	5⅜

Electric locomotive.—The latest electric locomotive actually constructed is one built jointly by the Baldwin Locomotive Works and the Westinghouse Electric Company. It resembles somewhat a large passenger car or tramcar, with doors in the middle, and mounted on two four-wheel trucks or bogies. The framing is of steel channels, fitted with a pilot or cowcatcher at each end. There is a short platform at each end, and a headlight is mounted on the hood of the roof over the platform. The dimensions are 32ft. in length and 9ft. in width. Each truck has a heavy steel frame, with plate springs over the axle-boxes, and double elliptical plate springs under each end of the bolsters. The wheels are 42in. diameter, with 6½in. axles, and each truck has two motors of 100-horse power, or 400-horse power in all, while designs have been prepared for a similar engine with four motors of 200-horse power. Air brakes are fitted, the air being supplied to the reservoirs by an air compressor within the cab, which also sounds the whistle. The motors are of the single gear type. The cab is of steel plate, with large windows, and can be used for baggage or passengers, a locomotive of this kind being adapted for the service of branch lines. The engine weighs about 50 net tons, and is capable of attaining high speeds. Arrangements have been made by the two firms mentioned for building all kinds of electric locomotives, for every kind of service, from switching or shunting engines to main line engines, and including engines for rack railways, light railways, street railways, &c.

Heavy goods engines.—The Union Pacific Railway has now in service an enormous locomotive of the Consolidation type—having eight driving wheels, and a two-wheel loading truck or bogie—with cylinders 22in. × 28in., and weighing 160,000 lb., of which 142,000 lb. are on the driving wheels, 4ft. 3in. diameter. The driving wheel base is 14ft. The boiler is 6ft. diameter, with 270 tubes 2¼in. diameter, and 13ft. 6in. long, while the fire-box is 3ft. 6in. × 10ft. 1in. An engine of similar type, but somewhat smaller, built for the Midland Terminal Railway, of Colorado, has the following dimensions :—

* Oesterreichs Wollen-und Leinen-Industrie, xvi., 174.

Cylinders	21in. × 26in.
Steam ports	18in. × 1¼in.
Exhaust ports	18in. × 2¾in.
Driving wheels	4ft. 4in.
Truck wheels	2ft. 6in.
Wheel base, driving	14ft. 4in.
Wheel base, total	22ft. 3in.
Weight on driving wheels	132,000 lb.
Weight, total	149,000 lb.
Blind tires on four middle wheels	
Boiler, wagon top ; diameter	5ft. 2¼in.
Boiler pressure	170 lb.
Fire-box, length	9ft.
„ width	3ft. 6¼in.
„ depth	5ft. 0¾in. to 5ft. 3¾in.
„ crown staying	crown bars
Tubes, number	258
„ diameter	2¼in.
„ length	13ft.
Grate area	31¾ square feet
Heating surface, tubes	1962¼ square feet
„ „ fire-box	162·3 square feet
„ „ total	2124·5 square feet
Smokestack, diameter at throat	16in.
„ diameter at top	19in.
Rail to top of smokestack	14ft. 9in.
Tender, eight wheels, diameter	2ft. 9in.
„ wheel base	15ft. 6½in.
„ capacity of tank	4000 galls.
„ capacity of coal space	11 tons.
„ weight, empty	40,100 lb.
Wheel base of engine and tender	48ft. 9⅜in.
Length over engine and tender	57ft. 6½in.

Compound locomotives.—The Chesapeake and Ohio Railway has recently put in service five compound locomotives of the Consolidation type—having eight coupled driving wheels and a two-wheeled leading truck or bogie—for the mountain division, where the ruling grades are 1 in 64. The engine has two cylinders, and its general dimensions are as follows :—

Cylinders	21in. × 24in. and 33in. × 24in.
Steam ports	1¼in. × 23in. and 1¾in. × 23in.
Exhaust ports	3in. × 23in. and 3½in. × 23in.
Connecting-rod, length	6ft. 11½in.
Driving wheels	4ft. 2in.
Truck wheels	2ft. 6in.
Journals, driving axles	7¾in. × 8½in.
Journal, truck axles	5in. × 9½in.
Main crank-pin	6in. × 6½in.
Wheel base, driving	15ft. 8in.
Wheel base, total	23ft. 5in.
Weight on driving wheels	127,000 lb.
Weight, total	143,000 lb.
Boiler (extended wagon top), diameter	5ft. 2in.
Fire-box	10ft. 1⅝in. × 2ft. 9⅜in.
Fire-box, thickness of plates	⅜in.
Tube plates, thickness	½in.
Crown sheet	radial-stay
Boiler pressure	200 lb.
Tubes, number	281
Tubes, diameter outside	2in.
Tubes, length over tube sheets	11ft. 10½in.
Grate, area	28·18 sq. feet
Heating surface, tubes	1744 sq. feet
Heating surface, fire-box	228 sq. feet
Heating surface, total	1972 sq. feet
Vaves, travel, high-pressure	6in.
Valves, travel, low-pressure	5½in.
Valves, outside lap, high-pressure and low-pressure	⁵⁄₁₆in.
Tender wheel (two four-wheeled bogies)	2ft. 9in.
Tender, length of frame	21ft. 2in.
Coal capacity	6 tons
Water capacity of tank	4000 gallons
Piston, high-pressure	cast iron
Piston, low-pressure	cast steel
Piston-rod, diameter	3¾in.

Well boring in Manitoba.—The return made by the Minister of Public Works as to well boring machines has some interesting information. The cost of the machines was : No. 1, 905 dols.; Nos. 2 and 3, 815 dols. The duty has been refunded by the Dominion Government. No 4. is an auger purchased from the Vulcan Iron Company for 150 dols. Duplicate parts and tools cost 572 dols. The cost of running the machines was: No. 1, wages expenses, 1505·32 dols.; repairs, 135 dols.; total, 1640 dols. No. 2, wages expenses, 1150·35 dols.; repairs, 35·90 dols.; total, 1186·25. No. 3, wages expenses, 1764·48 dols.; repairs, 31.88 dols.; total, 1796·36 dols. No. 4, wages expenses, 295·85 dols.; repairs, 24·41 dols.; total, 320·26 dols. The number of wells bored was as follows :—No. 1, 24 ; No. 2, 28 ; No. 3, 20 ; No. 4, 9. The plan of working is roughly to bore one well in a township in those parts of the province where difficulty has been experienced in finding water. The object is to prove at what depth water can be found, so that municipalities may purchase machines and bore wells for settlers. In this respect the effort has been fairly satisfactory. Of the wells put down two were in creameries, eight in public places, and the rest on private property. Where wells are bored on private land no charge is made the owners. They have to provide all the horses and manual labour required to run the machines, and board all employed on the work, including the superintendent in charge. When test wells have been sunk in all parts of the province the Government will have fulfilled the work undertaken and dispose of the machines.

A conduit electric railway in winter.—The two electric railways in New York which have the conductors laid in an underground conduit, like that of a cable railway, have recently been put to a severe practical test by heavy snowstorms, but neither the covering of the tracks by snow, or the subsequent slush in the tracks and in the conduit, caused any electrical trouble either in the conduit or on the cars. On the Lennox-avenue line the heavy storm of March 16th caused little interruption to traffic, the track being kept clear by sweeping machines, and no trouble being experienced with the electric conductors in the conduit. During the snowstorm of March 11th the operation of the road was hardly interfered with. The snow began to fall about 8 a.m., and the snow sweeper was started out over the line, but before it could make the complete trip the sprocket wheels of the broom broke, and it was necessary to push the sweeper back into the barn for repairs, where it remained until 4 p.m. Meanwhile the cars ran over the unswept tracks with no greater delay than would be ordinarily caused by considerable slipping of the car wheels on the snow-covered rails, the trips being about eight or ten minutes longer than usual. At some points the snow was drifted over the tracks by the wind, making it necessary for the motor man to back his car to get the necessary momentum to force the car through. After 4 p.m. the snow sweeper cleared the line, and schedule time was resumed. About 8 p.m. the storm turned to sleet and hail, which covered the rails with ice, but the cars were able to make their usual headway. On the Lexington-avenue electric conduit line a gang of men swept the tracks, and the cars made schedule time while the bad weather prevailed.

United States Navy.—The House of Representatives Committee on Naval Affairs has reached a formal agreement on the features of the Appropriation Bill for the next fiscal year, and has voted for four new battleships, five torpedo boats of the first-class, and ten torpedo boats of the second-class. The total amount carried by the Bill is 32,050,000 dols., or about 3,000,000 dols. more than that authorised by Congress last year. But included in this big sum are 5,300,000 dols. for construction and machinery and 3,890,000 dols. for armour and armament of vessels heretofore authorised. Not including the cost of the new vessels in this year's measure, it only carries about 28,000,000 dols. The cost of each new battleship is limited to 3,750,000 dols., and only 500,000 dols. is to be expended on each of them during the next fiscal year, or only 2,000,000 dols. in all. The contract price of the five first-class torpedo boats is not to exceed 175,000 dols., and the sum which can be spent on all of them between now and July 1st, 1897, by the Navy Department is limited to 656,000 dols. The cost of the ten second-class torpedo boats is fixed at 80,000 dols. each, and for the whole number only 600,000 dols. can be drawn upon in the next fiscal year· The majority of the committee, mindful of the condition of the Treasury and the discouraging outlook, voted, therefore, to keep down the expenditures for new ships to 3,256,000 dols. for the coming year. In the way of new legislation the Bill will provide for 1000 additional sailors and 500 more marines. The construction of dry docks at Algiers, La. ; Mare Island, Cal. ; and Portsmouth, N.-H., is authorised at a cost of 800,000 dols. for the former and 575,000 dols. for each of the two latter places. Only 100,000 dols. for each dock is to be available next year, however. Towards the armament of modern guns for auxiliary cruisers 250,000 dols. is appropriated, and for improvements at the Washington Gun Foundry 50,000 dols. The torpedo station gets 60,000 dols., and 50,000 dols. can be drawn upon to arm and equip the Naval Militia. For public works at the New York Navy Yard 75,000 dols., and 25,000 dols. to the Brooklyn Hospital for improvements. For repairs on the Miantonomoh, Bennington, Baltimore, Petrel, Mohican, Ranger, Atlanta, and Vesuvius, 350,000 dols. is made available. The Bill says that hereafter no wooden ships are to be repaired if the improvements exceed 10 per cent. of the original cost. For new boiler tubes for the Columbia, New York, and Minneapolis, the committee assigned 30,000 dols. New boilers for the Atlanta and Dolphin were authorised, and 150,000 dols. were provided to continue work on the machinery of the Chicago.

AUSTRALIAN NOTES.

The Victorian Government has passed a Bill embodying the engagement of a general manager for railways at a salary of £3500 per annum. An attempt was made to confine the selection within the Australasian colonies, but since the conference with the Upper House this clause has been rescinded.

Messrs. Joseph Baker and Sons, Melbourne, have secured the order for the supply of four large "Trusty" oil engines for driving the electric light at Coolgardie.

The New South Wales Government have offered a bonus of £1000 for the first discovery of payable gold at a depth of 2000ft. from the surface—hitherto all the gold won in the colony has been from very near the surface, while in Victoria mining has been carried on for some time at depths exceeding 2000ft.

Messrs. Hudson Brothers, Limited, engineers, Sydney, are proposing to adopt the co-operative principle with their employés such as that which has been in practice for some time with James Martin and Co., Gawler, South Australia. The system which obtains with the latter engineering firm is that those workmen in receipt of over 10s. per day have 15 per cent. taken off their wages, and those earning 10s. per day and under, 10 per cent. off, to go towards the purchase of shares. When the money thus retained reaches £4, a £5 share, of which £4 is paid up, is issued to the workmen.

Lysaght Brothers and Co. have secured the contract from the New South Wales Government for the supply of 105 miles of galvanised rabbit-proof wire netting.

The want of more rolling stock and locomotives on the West Australian railways is being severely felt, the goods arriving at the ports accumulating until transit is almost at a standstill. It is stated that within the last month 11,000 tons of goods are blocked at Freemantle, and no actual relief can be obtained until further supplies of rolling stock are received from England.

The railway department has placed orders with English firms for some £60,000 worth of rolling stock, and a similar expenditure on locomotives. Orders for locomotives are also placed with a colonial firm, so great is the demand.

AMERICAN NOTES.

(*From our own Correspondent.*)

New York, April 8th.

The extraordinary expansion of capacity in all industries has stimulated a spirit of trade organisation in several directions. The anthracite coal interests expect to restrict production and advance prices, and even to enter upon a heavy exportation of coal to Germany, for which preparations are in an advanced state. The business outlook is improving. Large foreign loans of capital are offered at 4 per cent. Bank clearings throughout the States during March were 5½ per cent. larger than March, 1895, 7 per cent. larger than March, 1894, and 11 per cent. less than March, 1893. For three months the aggregate clearings were 8 per cent. larger than same time last year, 16 per cent. larger than same time 1894, and nearly 25 per cent. less than same time 1893. Commercial failures for the last quarter are very large, 18 per cent. in excess of same time last year. The liabilities are unusually heavy. Gold exports begin to-day. The railroads are now profiting by the enormous corn movement. Steel billets have been advanced by a combination of manufacturers to 20 dols. Steel rails are 28 dols., Forge iron 11·50. The rolling mills are running slack. Plate mills are busier than others, and manufacturers of structural iron expect to be crowded with summer contract work in a few weeks. There is hesitation to rush into new industrial enterprises. Raw material is firm. Stocks of finished material are light, and mill, shop, and factory interests are waiting for orders to come. The tone of the market is strong, even with a moderate demand. Gold mining production this year will surprise the world, Colorado alone expects to dig out 30,000,000 dols. The rest of the region will double this.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

Fair attendance on 'Change. The demand for steam coal is moderate, pending arrival of vessels fixed for loading. Prices are without change. House coal shipments are good for the season, with prices steady. Tin-plates show no improvement, either in demand or price.

Prices :—Coal : Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron : Scotch warrants, 46s. 4½d.; hematite warrants, 48s. 2d., f.o.b. Cumberland ; Middlesbrough No. 3, 38s. 1d. prompt ; Middlesbrough hematite, 45s. 7½d. Iron ore : Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails, heavy sections, £4 12s. 6d.; light ditto, £5 to £5 5s., f.o.b.; Bessemer steel tin-plate bars, £4 ; Siemens tin-plate bars, best, £4 2s. 6d., all delivered in the district, cash less 2½ per cent. Tin-plates : Bessemer steel cokes, 9s.; Siemens coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C., 18s. 6d. to 20s. Pitwood, 15s. 3d. to 15s. 6d. London Exchange telegram : Copper, £44 10s.; Straits tin, £59. Freights steady.

A serious difficulty experienced with the screw propellers of torpedo-boat craft taken in connection with the thinness of the blades is the quickness with which they corrode. In one case the common steel propeller was found to be seriously corroded after three months. In the German Navy, a correspondent writes to the *Naval and Military Record*, experiments in the hope of getting rid of this drawback are being made with nickel steel for propeller blades in small crafts. So far the tests have proved satisfactory. After three months' trial the nickel steel was not corroded, while the common steel, with but an eight months' test, showed both metals to be corroded, though the nickel steel stood the best.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

During the week orders given verbally at the quarterly meeting have been confirmed by letter, and the works are now again engaged after the Easter holidays. A fair amount of work has been forthcoming as the result of those gatherings, and prices remain on the level then quoted.

Much satisfaction is expressed at the circumstance that the iron and steel exports for the quarter are so favourable. It is pointed out that the improvement in value for the quarter of iron and steel exports to all countries, compared with last year, has been 27 per cent., and in quantity as much as 36 per cent. The following advances in value, compared with last year, for the month and quarter respectively, are also received with feelings of gratification: Pig and puddled iron, 60 per cent. and 75 per cent.; bar, angle, bolt, and rod, 15 per cent. and 23 per cent.; railroad, 72 per cent. and 10 per cent.; ordinary wire, 22 per cent. and 28 per cent.; telegraph wire, 23 per cent. and 25 per cent.; cast and wrought iron, 18 per cent. and 28 per cent.; old iron, 91 per cent. and 104 per cent.; unwrought steel, 39 per cent. and 58 per cent.; galvanised sheets, 40 per cent. and 61 per cent. Hoops and sheets are better on the month by 8 per cent., but they show a decline for the quarter of 7 per cent.

The figure of £7, at which marked bars have remained for nearly three years, is still being quoted, and business in this class of iron has lately shown improvement. Unmarked bar quotations are irregular, the members of the Association being unable to obtain the list value of £5 15s., delivered, for common bars. Staffordshire and Shropshire common bars are sold as low as £5 5s. delivered, but the average is about £5 10s.; good merchant bars range from £5 12s. 6d. to £6. Galvanised sheet manufacturers are suffering from over-production and the competition of Welsh and a number of English and German houses, especially in the steel sheet branch. Galvanised corrugated sheets were quoted to-day at £10 to £11 per ton for 24 gauge, being at least £1 a ton lower than three months ago. The bulk of the contracts are accepted at the former figure, though sales involve loss rather than profit. Some of the best-known houses refuse to quote rather than accept the low rates offered by merchants and customers. Plain rolled sheets are suffering from the depression in the galvanised branch, singles realising £6 12s. 6d. to £7, and doubles £7 to £7 7s. 6d.

The competition in the tinned sheet trade has assumed a ruinous form, Welsh makers quoting lower prices than those of Staffordshire and Worcestershire houses, and a proposal has been moved for terminating the Tinned Sheet Association, which is an amalgamation of about half a dozen Worcestershire and Staffordshire firms, but it has been decided to carry on the Association for the present. The members of this body, at their recent quarterly meeting, resolved to reduce prices 2s. per cwt., which brings values down to the level at which they opened this year. Best coke sheets become 21s. per cwt. for two-ton lots, and charcoal sheets of large size 23s. Intermediate sizes are also reduced by 2s., and they now become :—Best cokes, 18s. per cwt.; and best charcoal, 19s. The new rate for any quantity under two-ton lots is 1s. extra on these prices.

In steel there is a steady business doing, Siemens marked steel slabs being imported from South Yorkshire at £5 a ton at stations ; basic quality, £4 7s. 6d. to £4 10s.; steel bars realise £6 to £6 10s. for Siemens, and £5 7s. 6d. to £6 for Bessemer quality ; Bessemer ship plates realising £5 15s., delivered, and best Siemens boiler plates, £7 to £8 10s., varying according to tests and size.

Derbyshire forge pig iron realises 42s. 6d. as an average; Northamptonshires, 41s.; Lincolns, 44s. 7d., at stations. Staffordshire cinder pig is well maintained at 36s. to 37s. for forge, and about 2s. more for foundry. All-mine are 55s. to 60s.

Cycle engineers in Birmingham and the district note with considerable curiosity the circumstance that at an extraordinary meeting in Dublin on the 13th inst. of the Pneumatic Tire Company, a resolution was passed authorising the disposal of the company to an English syndicate for the handsome sum of £3,000,000—three millions. The chairman announced that he had received a deposit of £1,000,000, which would become the property of the company if the purchase arrangements were not carried out. He mentioned that the shareholders had provided £75,000 in capital, and £185,000 in premiums, and had received £657,000 in dividends, while it was now proposed to give them £2,887,500, making altogether a total of some £3,545,000 in exchange for the money provided by them. A feature of the scheme adopted yesterday is to retain £80,000 for distribution among the employés and directors, when the sale is completed. When the auto-motor cars come into vogue perhaps a new era of usefulness will dawn for the pneumatic tire. It is understood that a wealthy rubber company is at the back of the new syndicate of purchasers.

Members of the Birmingham gun trade are perusing with interest a recent report in which the United States Consul in Liége describes the manufacture of and trade in Damascus gun-barrels, wholly hand-made, in the valley of the Vesdre, in that province. These barrels are for sporting guns. The annual production of Damascus barrels in the Vesdre Valley is about 300,000 pairs, of a value of about 3½ million francs. Of this the wages alone amount to about two million francs. The principal markets are Great Britain and the United States. About half the barrels made in the Vesdre Valley are sold to manufacturers of arms in Liége, to be mounted. The best sorts are made of a mixture of charcoal-iron and steel. Each barrel receives 150 welding heats whilst being forged.

The new Technical Schools which have been erected at Bath, at a cost of over £20,000, were opened on the 14th inst. by Sir William Hart Dyke.

Hydraulic engineers should note that Mr. E. P. Burd, one of the inspectors to the Local Government Board, has attended at the Guildhall, Shrewsbury, to hear evidence in reference to an application which has been made by the Town Council to the Board for a provisional order to amend the Waterworks Act of the Borough, so as to enable the Council to borrow a further amount for the purpose of water supply. Mr. Graham, of the Oxford Circuit, appeared for the Corporation, and Mr. Spearman for the Ratepayers' Association of the Borough. Mr. Graham explained that several schemes for a better water supply of the town had been adopted by the Council, but as they failed to meet with the approval of the ratepayers, none of them could be carried out. The present supply was, he declared, a disgrace to any town that called itself civilised, and was pumped from the Severn at Coton Hill, and supplied to the town without being filtered or strained.

About a year ago the New Conveyor Company acquired the engineering works of Messrs. Stone Bros. and Company, Smethwick, Birmingham, and all the workshops are now in full operation, equipped with modern tools for the economical and efficient manufacture of conveyors, elevators, gearing, coal screening, and coal-washing machinery.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The continued lull in the iron market here—due, however, mainly to special causes, to which I have previously referred in my notes—is having a temporary weakening effect upon prices. Not that makers are giving way to any appreciable extent, as for the present they prefer to go on with the contracts they have still on their books, rather than attempt to push sales ; but in the open market there is low selling going on, and the absence of buying of any weight coming forward in pig iron is necessarily rendering the position of makers of raw material not quite so strong as it has been. With, however, the steady improvement in the principal iron-using industries, the feeling remains one of general confidence with regard to the future. I have been making inquiries with regard to the shipment of American pig iron into this district, and other parts of the country, which have recently attracted some attention. In well-informed quarters these shipments do not excite any real concern, as they are looked upon as merely the result of American makers getting rid of surplus supplies at prices which they do not care to take at home, and which the exceptionally low freights ruling of late have enabled them to ship to this country under advantageous conditions. Certainly they are not looked upon as any attempt to establish a permanent business in the way of shipping iron to this country. I also hear from representatives of the iron trade just returned from America that the position of affairs in the States is not just now anything like so satisfactory as it has been, and this may further account for the getting rid of surplus iron by export.

There was again only a slow tone reported on Tuesday's Manchester Iron Exchange, and not more than a moderate attendance. For pig iron especially inquiry continues limited to small quantities, buyers who could place orders of any moment preferring to wait in the expectation that prices may be lower. Makers, however, who have generally sufficient iron under contract to go on with for the present, are holding to their list rates, but are booking only occasional small lots on this basis, and the general tone of the market is easier, iron in second hands being offered, in some cases, at under makers' prices. With regard to local and district brands, makers' quotations are unchanged, but not so firm in all cases, and in the open market Lincolnshire could be bought at about 6d. under quoted rates. Outside brands offering here are weaker in price. For delivery Manchester Docks, special brands of foundry Middlesbrough are offered at 45s., and at railway stations, 46s. 6d.; although makers' quotations are fully 6d. above these rates. Scotch iron makers ask about 47s. 6d. for Eglinton, and 48s. 6d. for Glengarnock, net prompt cash, delivered Lancashire ports, and 49s. 9d. to 50s. 6d. for Eglinton and Glengarnock respectively delivered dock quays Manchester, but quite 6d. under these figures would be taken by merchants.

In the manufactured iron trade makers are still securing a fair weight of new orders, and forges are kept fully employed, with late quotations well maintained. Delivered Manchester district, £5 10s. is the minimum for Lancashire, £5 12s. 6d. for North Staffordshire bars, and £7 10s. for sheets, with £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, 2s. 6d. less for shipment, still the Association list rates for hoops.

Nut and bolt makers, although not quite so busy as they were recently, are kept well engaged and prices are steady at recent rates.

No appreciable development of activity is noticeable in the steel trade here. For good foundry hematites makers do not quote under 58s. to 58s. 6d., less 2½, but merchants are prepared to sell at 6d. to 1s. below these prices, whilst ordinary steel billets are obtainable at £4 7s. 6d. to £4 10s. net cash, and £6 7s. 6d. represents about the average figure at which boiler-plates can be bought for delivery in this district.

In the metal market the recent push of buying has rather fallen off, but an active demand is still reported; and although the extra ¼d. per pound on brass and copper tubes is scarcely now being got, prices for these, as well as for other descriptions of manufactured goods, are firm at the full list rates.

I continue to hear very satisfactory reports from representatives of the engineering trades attending 'Change. Amongst boilermakers especially there has been a large amount of work given out recently, and one firm, which has a special plant for stamping boiler ends for most of the makers in the district, informed me that last month was a record in the number they had turned out, and that the present month promised to beat even last month. New work also still comes forward freely amongst locomotive builders, one or two good orders having been placed in this district during the last few days. With regard to other branches of engineering, the position remains much as I have previously reported, machine tool makers being all well supplied with work, stationary engine builders kept fully going, and other branches all well engaged.

The monthly report of the Amalgamated Society of Engineers, issued during the past week is equally as satisfactory as that of the Steam Engine Makers' Society, to which I referred in my last notes, with regard to the continued steady improvement in trade, the number of out-of-work members showing a further decrease, as compared with the previous month, and the reports as to the state of trade are of a more satisfactory character than they have been for several years past. Nearly all the districts record increasing activity generally, and in practically every department it is very exceptional where establishments have not work in hand to keep them fully employed. The Society has now under 3 per cent. of its total membership on the unemployed list, and the officials are hopeful that this percentage may be still further reduced during the next few months. In the Manchester district the position is even better than throughout the Society generally, the out-of-work list representing very little over 2 per cent. of the local membership, practically all the shops in the neighbourhood being fully employed.

Mr. Henry Hall, one of her Majesty's inspectors of mines, brought before the members of the Manchester Geological Society, at their meeting on Tuesday, a couple of self-igniting safety lamps, such as are now being largely used in German mines. One of these was a Wolf lamp, a German patent, and the other an ordinary Clanny lamp, both fitted with self-igniting apparatus, one of the lamps burning benzine, and the other colza oil, the igniting apparatus being equally effective in re-lighting either of the lamps. The igniting arrangement consists of a narrow tape, carrying on its surface at intervals small patches of fulminating material, this tape being fitted inside the lamp, in connection with a small upright shaft, similar to the pricker wire of an ordinary safety lamp. The tape passes from the bottom of the lamp up to the wick through a toothed clip, and by drawing the small shaft, which projects from underneath the lamp, quickly downwards, the fulminate on the tape is brought in contact with the teeth of the clip, and at once ignites, setting the portion of the tape projecting towards the lamp wick in flame, and then by leaning the lamp a little on one side this flame is brought in contact with the wick, and relights the lamp. One length of this tape is sufficient to relight the lamp from fifty to sixty times, so that under ordinary conditions the lamp might be in use for about a month without interfering with the apparatus. Mr. Hall, having experimented with the lamps, in order to show the working of the igniting apparatus, remarked that there were objections in some quarters to placing an apparatus of that kind in the hands of a collier, as it was held by many mining engineers that when a lamp was put out through any accident, it ought to be examined by some responsible person before being re-lighted. Against this objection, however, there were several advantages, the chief of which was that lamps were subject to being accidentally knocked out by the lads employed in carrying them to and from the face and the lamp stations, and there was the danger with the ordinary lamps of the men continuing their work in the dark, owing to their having no means to re-light them. The view taken in Germany, where these lamps with self-igniting apparatus were in general use, was that in case of a large explosion the use of such lamps enabled the workmen who were not injured, but whose lamps would in all probability be put out, to again procure a light which would, and had often, been the means of saving a considerable number of lives. He—Mr. Hall—thought this view of the matter was very important, as there could be no doubt that in case of an explosion a miner could scarcely be left in a more terrible position than being deprived of any means of procuring a light to help him in his escape. If it was thought unwise to put this apparatus for re-lighting lamps in the hands of a collier on the ground that an insecure lamp might thus be re-lighted, the apparatus might be so designed that it could only be operated by a fireman. Certainly such a re-lighting arrangement would take away the temptation to improperly open a lamp which had gone out, and there would be a saving of the expense incurred in employing boys to carry lamps from point to point for re-lighting. In a short discussion which followed, several inspectors of mines and mining engineers who were present expressed the opinion that such an igniting apparatus as had been shown would have to be very fully considered before it could be introduced into the mines of this country, and before it could be placed in the hands of the miners it would in all probability necessitate some special alteration of the present colliery rules. The general opinion, however, was that under certain conditions the colliers should have a means of re-lighting their lamps such as had been shown by Mr. Hall.

In the coal trade a depressed tone is the more or less general report. Pits are only in exceptional cases working more than four days per week, and supplies of all descriptions, except engine fuel, are plentiful in the market. House-fire qualities have been moving off moderately considering the time of the year, and prices are steady at late rates, but do not average more than 10s. for best Wigan Arley—less than this being taken in some cases for quantities, 8s. 6d. to 9s. for Pemberton four-foot and seconds Arley, and 6s. 6d. to 7s. for common house coals, at the pit mouth. Steam and forge coals still hang upon the market, with prices cut excessively low to effect clearances, whilst competition for ordinary business is exceedingly keen, and ordinary qualities at the pit mouth do not average more than 6s. to 6s. 6d. per ton. Engine fuel meets with a ready sale, some of the better qualities being rather scarce, if anything, and prices are firm at fully late rates, but, so far, attempts to secure advances have met with very little success, apart from one or two special cases. At the pit mouth common slack averages 3s. to 3s. 6d., and better sorts 4s. to 4s. 6d. per ton.

For shipment business continues slow, with prices as low as ever, common steam coals, delivered Garston Docks or High Level, Liverpool, or at the Partington Tips, Manchester Ship Canal, being readily obtainable at 6s. 9d. to 7s. 3d. per ton.

Barrow.—The hematite trade this week is rather weaker, but this is attributable to speculative influences, and not to any fluctuations in demand. Makers of pig iron are busy all round, and are very fully sold forward. Orders are offering freely for forward delivery, and prompt sales are at the moment the exception to the rule. Prices are firm at 50s. for mixed Bessemer numbers, net, f.o.b. Warrant iron is quoted at 48s. 2½d. sellers, 48s. 1½d. buyers, net cash. Stocks during the week have been reduced by 2979 tons, probably on account of the holidays and transactions of some weak holders. They now represent 303,918 tons held in warrant store-yards. There are still thirty-nine furnaces in blast, as compared with twenty-eight in the corresponding week of last year.

Iron ore is in brisk inquiry, and the local mines are being more actively worked, and particularly those that produce the best descriptions of metal; 10s. to 14s. 6d. is the range of prices from ordinary to best descriptions. Spanish ores are being more largely imported. This week five or six large cargoes have arrived at the docks at Barrow. Most of the smelters in the district are now using a proportion of Spanish ore. The price is steady at 12s. 6d. to 13s. per ton, f.o.b., 60 per cent. qualities, at West Coast ports.

Steel makers are very well off for orders, and rail and plate mills are very busy. Billets are in good demand, and the hoop trade remains very satisfactory. Overtime is being worked at the steel casting foundries, and good orders are on the market. Prices generally are firm. Ship plates are at £5 2s. 6d., but steel rails of heavy sections are down a little at £4 12s. 6d. per ton net f.o.b.

Shipbuilders and engineers are beginning to run short of orders, but tenders have been out for work for the Admiralty and commercial tonnage, which it is expected will result in renewed activity. Much progress is being made with the Admiralty work in hand, and it is anticipated H.M.S. Powerful will be ready to make her steam trials by June next.

The coal and coke trades are busy, and prices are stiffer for the latter, but easy for coal.

Shipping shows a temporary depression. The exports of pig iron from West Coast ports during the past week were 1414 tons, and of steel 3215 tons, as compared with 7480 tons of pig iron and 7023 tons of steel in the corresponding week of last year, a decrease of 6066 tons of pig iron and 3808 tons steel. The total shipments this year have reached 85,582 tons of pig iron and 116,528 tons of steel, as compared with 74,790 tons of pig iron and 105,610 tons of steel on the corresponding period of last year, an increase of 10,972 tons of pig iron and 10,918 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE Easter holidays are now over, and notwithstanding the fact that a considerable number of the pits was standing until well into the following week, not much animation has been felt in the South Yorkshire district. The collieries have been steadily employed since they resumed work. There is no appreciable improvement in the demand for household qualities of coal, and stocks at pits have been rather increased than otherwise during the last few weeks. The request from the Metropolis continues much the same as usual. Neither the Midland nor the Great Northern is carrying an average tonnage over their respective lines. This state of things, of course, has no beneficial effect on values, and in spite of all attempts made by owners to keep them up, they still continue to decline. Best Silkstones are obtainable at 8s. to 9s. 3d. per ton; ordinary, 6s. 9d.; Barnsley house, 7s. 3d. to 8s. 3d.; Flockton, 6s. 9d.; and thin seam from 6s. per ton. A better demand has set in for steam coal, the mild season we are at present experiencing favouring the early development of the export business. Prices continue fairly steady, with little prospect of advancing in face of the present keen competition. Barnsley hards are quoted at from 6s. 6d. to 7s. per ton for best sorts, while inferior qualities command about 6s. per ton. Gas coal is in rather weaker request, many of the pits curtailing their output considerably. Values are low at 6s. to 7s. per ton. Better reports are coming in with regard to manufacturing fuel. Small nuts fetch 4s. 6d. to 5s. 6d.; screened slack, 2s. 6d.; pit slack, 2s. 6d.; and smudge about 1s. to 1s. 6d. per ton. Coke is rather brisker, the demand from Lincolnshire, Northamptonshire, and other centres having advanced, and quotations range about 8s. 6d. to 10s. 6d. per ton.

The report of the coal business done by the Yorkshire ports with Hull, issued by the Hull Chamber of Commerce and Shipping, during the month ending March 31st, shows that the export trade has advanced considerably both on the month and the three months. During March last the coastwise trade amounted to 16,515 tons, which is an increase of 2030 tons over March, 1895. The total tonnage sent by local collieries amounted to 161,568 tons for the month, and 465,904 for the three months, as compared with 127,728 and 413,824 tons respectively for the corresponding month and quarter of 1895. Denaby Main is, as usual, the chief contributing market, with 20,424 tons, an increase of 128 tons over March of 1895; and for the quarter the weight is 64,944 tons, which is an increase of a little over 6000 tons. Monk Bretton comes second with 9600, against 4704, a very large increase, closely followed by Manvers Main, Carlton Main, and Aldwarke Main, with a little over 8000 tons each. The exports to foreign countries during March were 48,548 tons, an increase of 10,395 tons, and for the three months 145,117 tons, which is also a large increase over the same period of 1895. The increasing markets for the month were Sweden and Norway—10,817 tons, against 3130, an increase of 7867 tons—North Russia, South America, and Malta. For the quarter the increasing markets were Sweden and Norway, Italy, Holland, and Germany.

In the heavy industries of the city the holidays have been unusually short this year owing to the large amount of work in hand. In many cases business was carried right up to Good Friday night, and resumed again on Easter Monday or Tuesday. The make of both Bessemer and Siemens steel still continues very large. Hematite iron manufacturers refuse to receive contracts for forward delivery at the present prices, and many of the steel establishments are making no effort to book orders except on improved values. There is an exceedingly active request for crucible steel, more especially in the higher grades, and one Sheffield firm has secured a large order for the very finest steel that can be made. The railway material trade is also in a very good condition. Full employment is being given. As soon as the present orders are worked off fresh requirements are being placed. The iron market continues quiet with steady values. The engineering trades are not so well off for work as they were a few months ago. It is stated that Sheffield pays the highest rate of wages, London excepted, of any engineering locality in England. The Sheffield manufacturers complain that they are unduly handicapped thereby in the fight for orders.

Messrs. Thomas Firth and Sons, Norfolk Works, Sheffield, have received a good order for 12in. armour-piercing shells, and the Hadfield Steel Foundry Company have also obtained satisfactory orders for shells of lighter calibre.

In the lighter industries many of the large firms are complaining very much of the changeable state of the market. In many instances houses are well off for orders, while in others they have to keep their men employed by making goods for stock. Firms engaged in the silver and plating trades are fairly well engaged. Some very good requirements have just been received from the Indian market, and it is expected that before long a good business will be established with the various seaside resorts. Sheffield houses are confidently expecting that before long they will be receiving orders from the Admiralty for appointments for the various ironclads now in course of construction. These will mean considerable work, and will provide employment for many firms who have little work on hand.

Hardware and cutlery were sent away during March last to foreign and colonial markets to a value of £180,256, as compared with £149,713 for March of 1895. The principal increasing market, it is pleasant to note, has been Australasia, which has advanced from £19,112 to £32,479. Increased business has also been done by Russia, Sweden and Norway, Germany, Holland, Belgium, Faance, Spain and Canaries, United States, Chili, Brazil, the Argentine Republic, British Possessions in South Africa, and British North America. The only decreasing markets on the month were Belgium, Foreign West Indies, and East Indies.

In unwrought steel the value of the foreign trade for the month was £212,770, against £152,608. All the markets show an increase except France and the United States, the former having fallen from £12,515 to £9678, and the latter from £32,978 to £29,850. Germany, on the other hand, has increased from £28,621 to £43,983; British East Indies, from £7525 to £17,673; and Australasia, from £6169 to £11,112. The greatest increase on the month has been in railroad material, the exports exhibiting a total value of £250,610, as compared with £146,787 for March of 1895. This increase is in spite of the fact that no business whatever was done with Russia, Germany, Italy, and United States—at one time a very profitable market—while several other countries took only trifling amounts. Japan, which was expected to show a great increase, has fallen from £49,380 to £24,300. On the other hand, Mexico, to which only £99 worth was sent in March of 1895, took last month £14,389. The greatest advance, however, has been with our own Colonies, Australasia increasing its demand from £2034 to £32,037, and this is exceeded by British East Indies, the trade with which has gone up from £14,995 to no less than £102,518. South American business has also improved, the Argentine Republic having advanced from £1682 to £19,926; Brazil from £7721 to £11,843.

Messrs. William France and Co., proprietors of the London and Goole steamers, have established a service of steam barges between this city and Goole, by which means the goods which took three days to arrive by water from Hull are now delivered in fifteen hours. The service will be accelerated with the improvement of the canal, which is being vigorously proceeded with.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE iron and allied industries are at present suffering from one of those lulls in demand which are looked for at intervals during the progress of a revival, and this week very little new business has been transacted, indeed the market must be described as somewhat depressed, and pig iron prices at any rate are easier, while Cleveland warrants have touched a lower figure than has been known since January last. As is usual in a falling market buyers are disinclined to operate, but makers are also indifferent about selling, as they have plenty of orders on their books. But some of the merchants are offering pig iron more freely, and are competing strongly with the makers, taking prices, in fact, which the latter will not look at.

The producers' position is satisfactory. There is no lack of contracts in hand, and deliveries are very heavy—brisker even than those of last month, and there is every reason now to believe that the consumption is exceeding the output, and that a decrease of stock will be reported at the end of the month. The output will shortly be reduced by the blowing out of a furnace at Messrs. Gjers, Mills, and Co.'s Ayrescme Ironworks, Middlesbrough, for re-lining. At another works the output of Cleveland ordinary pig is to be reduced and more basic iron is to be made.

The exports continue very heavy, but some profess to believe that they cannot continue long at the present rate, as there must be a slackening earlier than usual, seeing that the shipping season practically opened nearly a month before the ordinary time, owing to the mild weather, and consumers abroad, who have generally got their chief supplies in April heretofore, obtained them in March this year. As yet, however, the shipments show no sign of any abatement, and producers are therefore very firm. Up to Wednesday night the shipments of pig iron from the Cleveland district amounted to 54,094 tons, as compared with 45,061 tons in March, and 55,167 tons in April last year. As regards last year the shipping season began exceptionally late owing to the severe weather of the first three months, and there was quite a rush of exports in April.

Owing to the competition of second hands, the price of No. 3 Cleveland G.M.B. pig iron for April, f.o.b. delivery, has been brought down to 38s., and some makers have even taken this from old customers, but generally it is a merchant's, and not a maker's price. Buyers have been able to purchase No. 3 for delivery up to the end of the half year at 38s. 3d., but very few people are buying this week, and there is no tendency at present to speculate, though most traders believe in the early resumption of activity, and do not look upon the present slackening with any apprehension; in fact, they simply regard it as an incident in the upward movement, which must be experienced now and then. No. 1 Cleveland pig iron is sold at 39s. 3d.; No. 4 foundry, at 37s. 6d.; grey forge, at 37s.; mottled, at 36s. 6d.; and white, at 36s., all for early delivery, but of the last named practically only a few tons can be secured, as none is being made, and the stocks are almost exhausted. An order for a thousand tons of white iron has been hawked about all over the district, but could not be executed, and the buyers had to accept a higher quality. For mixed numbers of East Coast hematite pig iron 46s. 3d. per ton is accepted.

The official accountants representing the Cleveland Ironmasters' Association, the Cleveland Blast Furnacemen's Association, and the North-Eastern Railway Company, after having examined the books of the ironmasters, declare that the average price obtained for the No. 3, delivered during the three months ending March 31st last, was 37s. 2·54d. per ton, this being 9·48d. increase on the previous quarter's average, and a figure not far short of the average quoted price. In accordance with the sliding scale arrangement the wages of blast furnacemen will as from the 4th inst. be advanced 1 per cent., and railway rates for iron-making materials, which are also regulated by sliding scale, based on the realised price of pig iron, will be advanced 1 per cent. also.

The blast furnacemen of Cleveland have resolved that they will on July 29th next hold a demonstration similar to that of August 11th, 1894, to talk over their position, and to enable them to carry out this project they have resolved to take holiday on that day, which will mean that the furnaces will have to stand for twenty-four hours. This will detrimentally affect the quantity and quality of the pig iron produced for some time afterwards.

On Monday night a serious explosion occurred at the Brancepeth Colliery between Durham and Bishop Auckland, and carried on by Messrs. Strakers and Love. Seventeen lives have been lost, and the accident would have been much more fatal to human life than it was if it had not occurred just when the men were changing shifts, and scarcely any but the store men were in. This is one of the chief coking coal collieries in Durham county, and the accident will lessen the supply of coke to the furnaces. Previously the production of coke was barely equal to requirements, and now, until the colliery is able to resume operations, there must be a scarcity, and it may be possible during the next week or two to secure 1s. to 1s. 6d. per ton advance. The workings of the colliery have been a good deal damaged, and it will be ten days or a fortnight before operations can be resumed. Besides this the working of other collieries with which the Brancepeth was connected has been interrupted. Owing to the disaster, Messrs. Straker and Love's make of coke is now not more than one-third the normal quantity.

The quarterly statistics of the Middlesbrough Chamber of Commerce show that there are within the port of Middlesbrough 91 blast furnaces, of which 72 are in operation, 44 producing ordinary Cleveland iron and 28 hematite, &c. The make of pig iron during the quarter was 590,171 tons, against 547,114 tons in the corresponding period of last year. Of the pig iron, 341,171 tons were ordinary Cleveland—24,057 tons in the first quarter last year—and 249,000 tons hematite, &c.—19,000 tons increase. The stock of Cleveland pig at Middlesbrough at March 31st was 344,915 tons—increase for quarter, 47,450 tons. Exports of pig iron from Middlesbrough reached 217,156 tons, against 165,878 tons in first quarter of last year. Of manufactured iron 61,317 tons were shipped, and of steel 56,852 tons; total 118,169 tons, against 81,480 tons last year. Of iron ore, 394,143 tons were imported, as compared with 294,630 tons in the previous quarter, and 284,449 tons in the corresponding quarter of last year.

In a paper read by Mr. A. S. Keith, of Middlesbrough, before the Cleveland Institution of Engineers, on "The Economical Use of Blast Furnace Gases," the author emphasised strongly the necessity for arresting the dust in the gases before their admission to the stoves and boilers; the use of larger gas tubes, and the provision of facilities for cleaning whilst the blast is on; the prevention of the escape of gas when the bell of the furnace is lowered for charging purposes; the use of water gauges for determining the pressure of the gases in the flues, &c. Mr. Keith gave a description of an invention by Mr. Tate, of Workington, for heating the air previous to its admission under the boilers by a series of regenerator chambers in the boiler seating. An interesting discussion took place.

Experiments have recently been made in the presence of experts in shipbuilding and engineering circles at Messrs. C. S. Swan and Hunter's yard on the Tyne, with the patent hydraulic steering gear designed by Messrs. Fawcett, Preston, and Co. The new gear is worked by a duplex pump amidships, oil being used instead of water, with the advantage that atmospheric changes are unfelt, and the action of the machinery is noiseless. There is said to be no likelihood of a breakdown taking place in the event of a heavy sea striking the rudder, as the hydraulic cylinder supplying the power also acts as an elastic brake, allowing the rudder to recede before the impact, the automatic readjustment preventing injury to either the gear or rudder.

Finished iron and steel works are well occupied, and prices are maintained at the figures ruling before the holidays, but new orders are somewhat scarce. On Tuesday Sir W. G. Armstrong, Mitchell, and Co., at Elswick-on-Tyne, launched the cruiser Esmeralda for the Chilian Government. Thirteen years ago they built an Esmeralda for the same country, but that vessel was sold last year to the Japanese by the Chilians. The new Esmeralda is of 7000 tons displacement, whereas the older vessel was of 3000 tons. Her speed will be 22½ knots, against the 18 knots of the old cruiser. For defence the new Esmeralda has a belt of 6in. Harveyised steel, equal in extent to three-fourths of her length, which includes all the vital parts of the ship. For offence she has an armament consisting of two 8in. guns and sixteen 6in. guns, also six 12-pounder guns, and a large number of smaller guns, besides the usual proportion of torpedo tubes. All the guns will be supplied from the Elswick Works. The old screw collier John Bowes, which was built in 1852 by Palmers, and which revolutionised the seaborne coal trade between the Tyne and the Thames, has been sold to an Irish owner. This vessel was the first screw collier, and vessels of her type rapidly superseded the old collier brigs which previously did all the trade.

The steam coal trade is somewhat better, and there is need of some improvement, for the accountants report that the average realised price of Northumberland steam coal during the quarter ending February 29th was only 5s. 0·77d. per ton, f.o.b., a decrease of 4·3d. on the previous quarter, and the wages of miners are reduced 2½ per cent. The collieries in West Durham, where the bulk of the coke is produced, are doing well, but those in the east of the county, which ship a large part of their produce, are very badly employed; indeed, the depression of trade has led to the closing altogether of several collieries.

The death is reported of Mr. Joseph M. Scott, son of Mr. W. H. Scott, and partner in the firm of Scott Brothers, iron, &c., merchants, Newcastle, Middlesbrough, and Cardiff. He died on board the s.s. Sir Charles Tennant, while on a voyage to Savona for his health.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been in a rather backward condition this week, prices giving way to a lower point than they touched in the preceding week, when a drop of about 6d. per ton took place in Scotch warrants. Seeing that the strength had gone out of the market for the time, holders of warrants have been disposed to realise, and in addition to this it is reported that there has been some disposition on the part of operators to sell for a fall in price. Business has been done in Scotch warrants from 46s. 5½d. to 46s. 3d. cash and 46s. 8d. to 46s. 5½d. one month. In Cleveland warrants there has been scarcely anything doing. The prices quoted on 'Change are 38s. 1½d. to 37s. 11d. cash and 38s. 3½d. to 38s. 1½d. one month. Hematite warrants have been quiet at 48s. 3½d. to 48s. 1½d. cash and 48s. 6d. to 48s. 3d. one month.

There is comparatively little Scotch pig iron now going into the Glasgow warrant stores, but it is understood that makers are of necessity increasing their private holdings to some extent. The furnaces in blast number 81, compared with 75 this time last year. Of these 43 are producing ordinary, 33 hematite, and 3 basic pigs.

The prices of Scotch makers' pig iron are easier, but nominally there is so far not much change:—Govan and Monkland, Nos. 1, are quoted f.o.b. at Glasgow, 47s. 6d.; Nos. 3, 46s.; Carnbroe, No. 1, 48s.; No. 3, 46s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, Calder, and Summerlee, Nos. 1, 51s.; No. 3, 48s. 6d.; Coltness, No. 1, 53s.; No. 3, 48s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s. 6d.; Eglinton, No. 1, 48s.; No. 3, 46s.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s. 6d.; No. 3, 49s.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

The consumption of Scotch pigs at home is good, and fair quantities are also being dispatched to the English coast; but inquiries from abroad are poor, and the shipments have been going back in amount. The clearances from the different ports in the past week have amounted to 5593 tons, compared with 8117 tons in the corresponding week of last year.

The finished iron trade is quiet, with a fair amount of material going into use. So far as regards prices, the tone of the market has been adversely affected by reports from Staffordshire and elsewhere, which appear to indicate that trade is not progressing as could be desired. In the steel trade there is no abatement of activity. A great deal of work is in progress, and new orders are constantly being placed.

The prospects of the pipe-founding branch are a little more encouraging, there being numerous inquiries in the market for pipes for municipal contracts. The tube makers are in some instances very busy.

The position of the coal trade is very discouraging, especially in the shipping department, which in the regular order of things ought now to be looking better. The total clearances from the Scottish ports in the past week have amounted to only 114,878 tons, compared with 165,270 in the preceding week, and 141,968 in the corresponding week of last year. There is no change in prices.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

WHAT with holiday influences and depression in trade at the tin-plate works, the iron and steel works on the hills have not been in an active state of late, and for the first time for a long period the only activity seen at Cyfarthfa was at the blast furnaces, the mills being practically at stop owing to deficient orders. It is intended, I hear, that Cyfarthfa should resume its ore and steel rail manufacture, which may make partial amends for a failing steel bar trade. Welsh ironmasters generally are doing their best, both as regards quality and price, to secure the colonial and foreign orders that are moving about.

Only two despatches of any interest occurred last week—1400 tons of rails to Mombassa from Cardiff, and 190 tons from Newport for Exmouth. Slackness, however, should be expected for a little time, and I am glad to know that a strong impression exists in the revival of the iron and steel industry, though, as reported on 'Change, Cardiff, this week, "the new business coming in is of a very meagre character."

On 'Change, Swansea, mid week, a good deal of interest was aroused in the examination of a specimen of terne plate roofing, which it is hoped is to start a new industry, and do away with slates and tiles. After a thorough examination of quality and prices, a deputation was named to wait upon the Corporation this week, and urge them to roof the new market house with terne sheets, and in other respects follow the American lead. Colonel Wright, a well-known representative of the tin-plate trade, will head the deputation, and the movement is cordially hailed as a hopeful one, and calculated to improve the present condition of things.

Stocks of iron ore continue to come in pretty freely from Bilbao. At one of the leading works last week I was interested in seeing that the "stock" held—only a moderate one, by the way, as the tendency now is to run the ore wagons to the top of the furnaces—was not, as previously noticed, only of Spanish, Tafna, Bilbao, &c., but composed of Northampton ores, old Welsh argillaceous ores, and Bilbao. There is still a lurking regard for old Welsh, which is admirable for cold blast purposes and special requirements, and a constant trade for this article is going on between Wales and Staffordshire.

It will be seen from last quotations, Swansea Exchange this week, that prices are in abeyance. Pig iron, little doing, slight falling off from last week in Glasgow warrants, last prices 46s. 3d. cash buyers. Middlesbrough No. 3, 38s.; hematite, 45s. 8d.; Welsh bars, £5 10s. to £5 12s. 6d.; angles at usual extras. Sheet iron, £6 15s. to £6 17s. 6d.; steel sheets, £6 10s. to £6 12s. 6d.; steel rails, heavy section, £4 10s. to £4 12s. 6d.; light, £4 17s. 6d. to £5 7s. 6d. Bessemer steel, tin-plate bars, £3 17s. 6d.; Siemens tin-plate bars, best, £3 18s., all delivered in district, net cash. Siemens coke tin-plate, 9s. 1½d. to 9s. 3d.; Bessemer, 9s. to 9s. 1½d.; ternes per double box, 28 by 20 c., 16s. 6d., 17s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 12s. 9d.

The Exchange report on the tin-plate situation conveys all of interest in a few lines. There is no improvement to report in tin-plates. The production and shipment are about equal, with a slight increase in the stocks, and the result of the Birmingham meeting did not bring many orders. Block tin is at £59 1s. 3d. to £59 3s. 9d. Copper shows a fall of about 27s. 6d. per ton on the week.

There is a slight improvement to be recorded at Llanelly, a settlement having been come to at the Old Castle Works. The "behinders" and the "risers" concede 10 per cent., and on all piece-work 15 per cent. is to be deducted.

The Pacific Steam Navigation Company directors are about entering into contract for a supply of 60,000 to 75,000 tons best Welsh coal, to be shipped at Cardiff, Newport, Barry, or Swansea.

The Dowlais Company at its deep sinking, Aberdare Junction, appears at length to have surmounted the formidable obstacles met with at the Dowlais-Cardiff Colliery, and in a very short time a steady output is assured, and a great increase in the number of men. Nothing but a very large capital at the back, and the greatest perseverance and skill, could have brought about a successful ending to this great enterprise.

The water trouble, which nearly wrecked Penrhiwceiber, has been the great enemy all along, and a source of incessant anxiety. A coalowner commenting upon the success, pertinently remarked that such great ventures were nearly, if not quite, at an end. But there is the uncertainty of winning coal at all, then the constant paying out of large sums, and when all is said to be plain sailing, coal won, and a demand secured, there is the difficulty with labour. As a large colliery owner remarked a few years ago to the writer, that had he known all this he should have put his money in the 3 per cents. I mention this in order to show that the lot of colliery owners is not all happiness.

The latest report from Cardiff Exchange indicates more activity in the outward freight market, and shows increased steamers secured for loading forthwith, several of large tonnage. Prices remain. Best steam is quoted at 10s. 3d. to 10s. 6d.; seconds, 9s. 3d. to 9s. 9d.; drys, 8s. 9d. to 9s. 3d.; best Monmouthshire, 8s. to 8s. 6d.; seconds, 7s. 9d. to 8s.; best small, 4s. 9d. to 5s.; second best, 4s. 6d.; seconds, 4s. to 4s. 3d.; drys, 3s. 6d. House coal remains dull. Prices:—Best, 10s. to 10s. 6d.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 6d. to 7s. 9d.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. 1½d. to 7s. 3d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d.; patent fuel, 10s. 3d. to 10s. 6d.; coke, furnace, 12s. 9d. to 15s.; foundry, 18s. 6d. to 19s.; pitwood, 14s. 9d. to 15s. Patent fuel and coke are in good demand.

By a majority of three the Newport County Council this week carried Colonel Lyne's motion to go on with the waterworks. The minority wished again to consult the ratepayers.

A strong impression prevails in Cardiff that the union between the Bute Docks and the Rhymney Railway may soon be regarded as an accomplished fact. A difficulty has arisen at Swansea with regard to the dock extension, the Ocean Dry Dock and Corporation submitting alternative proposals, but no decision has yet been arrived at. The Llanelly Harbour improvements are temporarily blocked by an adverse report of the Board of Trade, which expresses the opinion that the south training wall is wholly unnecessary. There is an intention of selecting a deputation to confer with the Board, when Sir Alexander Rendel and Mr. Fowler will defend their case.

I much regret to announce the death of Captain Lewis Lewis, brother of Sir W. T. Lewis, Bart., and at one time chief mineral agent for the Dynevor estate. He was a gentleman of considerable ability, but had for many years retired from public life.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

DURING the week that followed the Easter holidays a certain quietness has naturally been noticeable on the iron markets, but prices continued to be firm and inclined to rise, and with the increasing demand that will undoubtedly be experienced after this week, the outlook in the iron trade will become even more favourable than before.

In Silesia the different branches of the iron industry have been steadily occupied; the bar and girder trade is specially well off for new work, and there is likewise a good activity secured to the railway department, orders of considerable weight having lately been given out.

The position of the Austro-Hungarian iron market does not show any material change. Both raw and manufactured iron continue in regular inquiry, and a further improvement in demand is expected to take place before long.

All sorts of structural iron are selling briskly, and for bars higher prices are willingly paid, consumers and dealers knowing well that they will have to pay more if they wait till next month. Hardware and tools have, until now, been in languid request generally.

On the French iron market the upward tendency in prices seems to have further increased upon the week. Bars are scarcely obtainable at 140f. p.t., girders being, as a rule, sold at 160f. p.t., which is about 10f. p.t. more than was asked last month. Thanks to the firm tone on foreign markets, the export quotations are pretty favourable. Steel rails have recently been sold at 162f. p.t., f.o.b. Bordeaux; for heavy plates, 172f. p.t. may be considered as basic quotation.

The activity in the various departments of the Belgian iron industry continues altogether favourable, though business has on the whole been a trifle more quiet during the past week. But there has been no yielding in prices, at least not for home demand.

In the export trade, on the other hand, English competition has of late been felt very keenly, and makers have repeatedly been obliged to grant concessions. The blast furnace works are specially well off for new work; Athus has just sold 8000 t., at 50f. p.t., which shows a difference of 8·50f. against the low rates of last quarter. In consequence of the increased cost of production plates have been raised 5f. p.t., No. 2, f.o.b. Antwerp now standing on 145f. p.t., No. 3 155f. p.t. Plates, No. 2, for export are quoted 140f. p.t.; No. 3, 150f. p.t.; steel plates rose on 155f. p.t. There is talk of some additional blast furnaces being blown in next month. Production of iron and steel in Belgium during the last three years was as under:—

	1893. Tons.	1894. Tons.	1895. Tons.
Foundry pig	74,630	80,110	85,450
Forge pig	428,480	378,045	329,651
Bessemer, basic	242,154	360,442	414,034
	745,264	818,597	829,135
Plates, rails	113,602	118,596	101,479
Various articles of manufactured iron	371,419	334,694	351,901
	485,021	453,290	453,380
Steel billets, cast steel	373,113	405,661	455,550
Plates, steel rails, &c.	224,922	341,318	392,332

Belgian export to East India, China, and Japan was, for the last three years, as under:—

British East India.

	1895. Tons.	1894. Tons.	1893. Tons.
Rolling material	2,280	1,715	119
Steel girders	3,061	614	111
Steel bars	5,193	2,791	1,938
Steel nails	468	—	—
Iron girders	4,929	4,486	4,773
Iron plates	11,663	9,640	10,238
Iron bars	42,928	35,506	28,860

	34,640	28,259	15,747	7102

This year's spring demand is very strong on the Rhenish-Westphalian iron market, and the firm, or rather increasing, tendency consequently continues. A healthy tone characterises the iron ore trade; only in the Siegerland the business in spathose iron ore has perhaps been a trifle more quiet just recently. List rates are for spathose iron ore, raw, M. 9 to 9·60 p.t.; the same, roasted, M. 12 to 13·70 p.t. Roasted calcined iron ore is quoted M. 12 to 14 p.t.; Nassau red iron ore, 50 p.c. contents, M. 9·50 p.t. For minette of Lorraine, which is in fairly active request, M. 2·60 to 2·80 and 3·40 p.t. is paid, according to the quality required. The tone of the pig iron market is strong, the majority of the blast-furnace works having already disposed of their output for this and the next quarter. In spite of the present favourable condition of the iron trade, owners have resolved to desist from a further rise in prices. Last week's quotations for the different sorts of pig iron were:—Spiegeleisen, 10 to 12 p.c. grade, M. 58 to 59 p.t.; forge pig, No. 1, both Siegerland and Rhenish-Westphalian qualities, M. 53 to 55 p.t.; No. 3, M. 42 p.t. Hematite, M. 65 p.t. Foundry pig, No. 1, M. 65 p.t.; No. 3, M. 57 p.t.; basic, M. 56 p.t. German Bessemer, M. 60 p.t. Iron for making steel, M. 56 p.t.

The business in malleable iron continues to show a very satisfactory improvement; prices are firm and are even yielding some profit. Bars and girders sell briskly, and there has been a change for the better noticeable in hoops lately. Plates as well as sheets continue in active demand. There is nothing of interest to be related concerning the wire and wire nail department, a limited business being generally done. Rivets, on the other hand, show more life, and a rise in prices has taken place.

The following are the latest list quotations per ton at works:—Good merchant bars, M. 118; angles, M. 128; girders, M. 92 to 95; hoops, M. 127 to 130; billets in basic and Bessemer, M. 84 to 85; heavy plates for boilermaking purposes, M. 160; tank do., M. 135 to 140; steel plates, M. 130 to 135; tank do., M. 120; sheets, M. 155 to 160; iron wire rods, common quality, M. 125; drawn wire in iron or steel, M. 138 to 140; wire nails, M. 127 to 130; rivet iron, M. 138 to 142; rivets, good merchant quality, for boilers, bridges, &c., M. 175 to 180; complete sets of wheels and axles, M. 280 to 290; axles, M. 220; steel tires, M. 200; steel rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120; light section rails, M. 98 to 100.

LAUNCHES AND TRIAL TRIPS.

The largest turret steamer yet built, recently left the Wear for her trial trip. She is the s.s. Selma, built for Messrs. George Horsley and Son, of Hartlepool, by Messrs. William Doxford and Sons, Pallion, and has a deadweight capacity of rather over 5600 tons. After adjusting compasses the vessel was put on the measured mile, when a mean speed of 10. 6 knots was attained.

On the 10th inst. the steel twin-screw cable steamer Okinawa Maru completed her official trials on the Clyde. She is a spar-decked vessel, arranged and fitted for laying and repairing ocean telegraph cables, built and engined by Messrs. Lobnitz and Co., Renfrew, to the instructions of Mr. A. R. Brown, Glasgow, for the Japanese Government. Her dimensions are:—290ft. by 40ft. by 24ft. 6in., moulded; and the trials in all respects gave satisfactory results.

On Monday, the 13th inst., the s.s. Dorothy was handed over to her owners, Messrs. J. S. Allison and Co., West Hartlepool, by Messrs. Ropner and Son, Stockton-on-Tees, by whom she has been built. The steamer proceeded down the river with a large company of ladies and gentlemen on board, and on her arrival in the Tees Bay, the compasses were duly adjusted, after which a very pleasant and satisfactory run was made to the Tyne; the machinery, which has been supplied by Messrs. Thos. Richardson and Sons, Hartlepool, working in a highly satisfactory manner. The owners, who were present at the trip, expressed their entire satisfaction on the results of the trial, both in regard to the vessel and the machinery, &c. The steamer will load in the Tyne for a Mediterranean port.

On Friday, April 10th, 1896, the steel spar-deck steamer Minneburg, built by Sir Raylton Dixon and Co., Cleveland Dockyards, Middlesbrough, for the Hansa Steamship Company, Bremen, was taken out to sea for her official trial trip, under the command of Captain Schwarz. Her dimensions are:—Length, 323ft.; beam, extreme, 42ft. 6in.; depth, moulded, 25ft.; with a deadweight capacity of about 3600 tons. The poop, bridge, and forecastle decks are of teak, and handsome accommodation is provided for captain, officers, and engineers in houses on bridge deck. Quadruple expansion engines, built to German law requirements, have been supplied by Messrs. Wigham, Richardson, and Co., Newcastle-on-Tyne, having cylinders 19¼in., 28in., 42in., 61in., by 42in. stroke, with two large boilers working at 215 lb. pressure. The hull and machinery have been constructed under the supervision of Mr. D. Wulff, superintendent engineer of the Hansa Company, and have been specially designed for the River Plate trade. At the conclusion of the trial, which passed off most successfully, the vessel proceeded to Bremen to load.

Messrs. David J. Dunlop and Co., Inch Works, Port Glasgow, have recently launched the steel twin-screw steamer Ibadan, built to the order of the African Steamship Company, of London, for their branch service on the West Coast of Africa, and immediately thereafter was moored alongside the yard wharf to receive her machinery, &c., consisting of two sets of triple-expansion engines of the latest and most modern design. The Ibadan is a duplicate of a steamer built and engined by Messrs. Dunlop also for light draught service, her dimensions being:—Length, 204ft.; beam, 35ft.; and moulded depth, 13ft.; the gross tonnage being about 800 tons. All arrangements for easily maintaining steam in the tropics are being fitted. The steam steering gear is Harrison's patent, the engine being placed in the engine-room directly under the control of the engineers. The deck machinery includes direct steam windlass and five steam winches, all of Messrs. Clarke, Chapman, and Co.'s make, with their derricks. The poop, bridge, and forecastle, which are arranged to give exceptionally good light and ventilation, are fitted with cabins and saloons for officers, engineers, &c., the crew and firemen being located under the forecastle. The captain's cabin is fitted on the bridge deck in a large teak deckhouse. From this bridge the steamer is navigated. Awnings over the entire length of the vessel are provided, those over the poop and steam winches being fitted of steel framing, with canvas covered tongued and grooved planking. The rig is that of a two-masted fore-and-aft schooner. It is expected the Ibadan will be ready for sea in about a fortnight.

On Tuesday, April 14th, Messrs. Furness, Withy and Co., launched from their shipbuilding yard at Hartlepool a large steel screw steamer, built to the order of Messrs. T. Wilson, Sons and Co., Hull. She is a fine type of modern cargo boat, measuring over 340ft. in length, and built throughout of Siemens-Martin steel, with a large measurement and deadweight capacity, and built to the highest class at British Corporation, this being the third vessel built by Furness, Withy and Co., for Messrs. Wilson under this classification within the last twelve months. The vessel is built on the spar deck principle, with long bridge, poop, and topgallant forecastle. The holds are fitted with wood shifting boards, and all deck, deck erections, skylights, bulwarks, bulkheads, &c., are constructed of steel and iron. Cellular double-bottom fitted all fore-and-aft for water ballast, the after peak being also available as a tank. The greater portion of the plates are in 24ft. lengths, making the structure of the ship very strong. Six steam winches, patent steam steering gear amidships, screw gear aft, direct steam patent windlass, stockless anchors, hauling into hawse-pipes, and other modern appliances are fitted for the handy working of the vessel. The saloon and cabin providing accommodation for the captain, &c., is handsomely finished in polished hardwood. The steamer will be rigged as a two-masted fore-and-aft schooner, and has been constructed under the supervision of Mr. J. T. Wilkins. She will be fitted with three large boilers and triple-expansion engines of massive design by Messrs. Westgarth, English, and Co., Middlesbrough, with every provision for economical working at a minimum cost of upkeep. The machinery has been built under the supervision of Mr. Spear, superintendent engineer for Messrs. Wilson. On leaving the ways she was named Horatio by Mrs. H. Withy, Brantford House, West Hartlepool.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

31st March, 1896.

7001. Covering Lacing Studs, F. Egge and N. M Beach, London.
7002. Production of Ammonia, H. H. Lake.—(*L. Sternberg, United States.*)
7003. Separating Oil, J. S. L. Wharton and W. S. Hallowell, London.
7004. Machines for Knitting Socks, &c., F. Moore, London.
7005. Electric Hammers, H. H. Lake.—(*A. S. Barnes and P. S. Skinner, United States.*)
7006. Vices, W. Thompson, London.
7007. Printing Presses, H. H. Lake.—(*L. Benedict, United States.*)
7008. Universal and Geographical Clock, D. W. Thompson, London.
7009. Funeral Carriages, R. A. McCauley, London.
7010. Curling Stones, C. T. Jacoby, London.
7011. Scissors Protectors, W. I. Hadden, London.
7012. Steam Generators, G. F. G. Des Vignes and S. H. Terry, London.
7013. Electric Motors, J. Devonshire.—(*C. P. Steinmetz, United States.*)
7014. Regulating Valves, J. H. Gartrell, London.
7015. Dental Tools, A. J. Brown and R. S. Anderson, London.
7016. Toilet Tray, C. M. Pritt, London.
7017. A Self-adjusting Collar Stud, F. Garthwaite, London.
7018. Coffins, C. S. Bowker, London.
7019. Watch, Clock, and other Dials, W. H. Cox, London.
7020. Boots, A. Cornish, London.
7021. Making Tubes, W. P. Thompson.—(*La Société Delaperrière, Dida and Aubin, and L. Chambon, France.*)
7022. Match Receptacles, A. H. Booth, London.
7023. Manufacture of Cement, &c., O. J. Owen, Liverpool.
7024. Clarionets, J. Wallis and Son.—(*A. Cottereau, France.*)
7025. Washing Machines, J. Pickering, London.
7026. Cycle Racks, G. D. Young and W. F. Day, London.
7027. Cycle Stand, R. Willshaw and W. Dixon, Bedford.
7028. Machines for Breaking Coal, U. Ammann, London.
7029. Roofing Tiles, A. Weil, London.
7030. Cycles, W. F. Williams, London.
7031. Propulsion of Manumotive Carriages, H. V. Weyde, London.
7032. Treating Wood, A. M. Clark.—(*The Electric Fireproofing Company, United States.*)
7033. Cigarette-making Machines, A. J. Boult.—(*H. F. Wolf, Germany.*)
7034. Burial Casket Boxes, J. J. Stephens, London.
7035. Mine Trap Doors, J. O. Brien, London.
7036. Gas and other Motors, J. F. Duryea, London.
7037. Machines for Making Wire Handles, D. L. Hill, London.
7038. Regulators for Electric Arc Lamps, H. Bäurlin, London.
7039. Cycle Saddles, R. Haddan.—(*J. Chaix, France.*)
7040. Screw-cutting Tools, &c., M. Rosenhammer, London.
7041. Preservation of Milk, Cream, &c., H. Higgins, London.
7042. Preservation of Foods, &c., H. Higgins, London.
7043. Colour-producing Aromatic Diamine, G. H. Weiss, London.
7044. Ladies' Skirts, A. S. Phillips, London.
7045. Automatic Machine Guns, H. S. Maxim, London.
7046. Securing Canvas Covers to Barrels, H. C. McLean, London.
7047. Railway Spikes, H. J. Vaughan, London.
7048. Fastening Devices for Neckties, R. D'Altoni, London.
7049. Nut Locks, T. Oldroyd, London.
7050. Puzzles, W. E. Conger and F. J. McDonald, London.

7052. Supports for Nursery Bottles, W. A. Rowan, London.
7053. Bottles, J. Neubauer, London.
7054. Electrical Signal Systems, L. C. Werner, London.
7055. Stoppers for Measuring Devices, C. E. Wyckoff, London.
7056. Cutting Machine, W. H. Wheatley.—(*The Seybold Machine Company, United States.*)

1st April, 1896.

7057. Pumps, Water Motors, &c., F. Lamplough, London.
7058. Ink Pads, J. H. Mason and A. M. Eaton, London.
7059. Motor Roof Ladders, J. R. Hamilton, Waltham Cross.
7060. Steadying Tip Carts, J. Newby, West Bromwich.
7061. Outlet Ventilator for Hats, D. Cross, Timperley.
7062. Obtaining Potassic Cyanides, A. C. Thomson, Glasgow.
7063. Connecting Blouses to Skirts, M. A. S. Jackson, Glasgow.
7064. Pole for Lowering Windows, W. Thomas, Glasgow.
7065. Decorating Fire Brasses, C. Meason, L. E. Wood, T. B. Davis, and A. Mawson, Birmingham.
7066. Bottles, J. Ireland, Blackpool.
7067. Laundry Irons, Richmond and Co., Ld., and E. W. T. Richmond, Liverpool.
7068. Coin-freed Automatic Machine, F. J. Shapley, Bristol.
7069. Syphon Flushing Cisterns, H. Crudgington, Birmingham.
7070. Domestic and the like Fire-places, S. Hurd, Leeds.
7071. Bed Rest, S. A. Lee, J. Studdard, and E. G. Coward, Huddersfield.
7072. Gas Stoves, J. E. Eccles, Halifax.
7073. Seats for Cycles, S. Rozene and W. Hobkirk, Halifax.
7074. Lamp for High Voltages, A. J. Beaumont, York.
7075. Method of Obtaining Motive Power, D. Cook, London.
7076. Infusing Coffee, Tea, &c., G. R. Burdass, Staffs.
7077. Dressing Grain, C. E. Mumford and W W. Willis, Ipswich.
7078. Jars, R. C. Baker, London.
7079. Pulley forDrawing Wire, E. Oddy and B. Woodcock, Yorks.
7080. Travelling Trunks, J. Lewis, Wolverhampton.
7081. Tool Holder, S. H. Wright and G. Webb, Monmouth.
7082. Production of Acetylene Gas, A. G. Wild, Sheffield.
7083. Roof Glazing, J. Mellowes, Sheffield.
7084. Pneumatic Tires for Cycles, G. H. Gardner, London.
7085. Manufacturing Fuel, W Wardle, Burton-on-Trent.
7086. Spring Centre for Wheels, F. E. Jones, Birmingham.
7087. Lamp, F. E. Jones, Birmingham.
7088. Toy, A. N. Mezzetti, London.
7089. Drawing-off Beef Tea, J. M. Tucker, Bedfordshire.
7090. Wheels and Tires for Cycles, W. C Morton, London.
7091. Manufacture of Boots and Shoes, A. Parry, Manchester.
7092. Knees for Wagons, J. Mather and G. Newman, Lancs.
7093. Roofing Dwelling Houses, A. W. Evans, Monmouthshire.
7094. Rendering Fabrics Waterproof, A. A. Haigh, Manchester.
7095. Engines, W. Bowden and R. J. Urquhart, Manchester.
7096. Bicycles, G. H. Richmond and J. Crowther, Manchester.
7097. Straps, &c., W. Brierley.—(*P. Eichelmann, Germany.*)
7098. Brushes, E. Cardot, Brussels.
7099. The "Rapid" Cartridge Carrier, J. Mecredy, London.
7100. Puzzle, F. C. Higgins, London.
7101. Permanent Way of Railways, C. H. Sadler, Cardiff.
7102. Construction of Reservoirs, D. K. C. Russell, Edinburgh.
7103. Spring Balances, I. A. Timmis and P. Ward, London.
7104. Dampening Device for Copying, W. S. Hampsher, New York.
7105. Safety Gear for Mining Cages, S. Arnold, London.
7106. Saucepans, Boiling-pans, T. and D. Llewellyn, London.
7107. Instrument for Shaping Teeth, F. Frost, London.
7108. Hats, J. A. Cumine, C. Woerner, and F. Ritter, London.
7109. Clubs for Playing Hockey, F. H. Ayres, London.
7110. Velocipede Handles, F. H. Ayres and E. Grimsdell, London.
7111. Paper Knife and Book Marker, W. Gallatly, London.
7112. Toasting Forks, W. Gallatly, London.
7113. Device for Clerical Purposes, H. Womack, London.
7114. Device for Curative Purposes, F. J. Reddaway, London.
7115. Device for Holding Cloaks, G. Warnkes, London.
7116. Funnels, G. John, London.
7117. Reels, R. Leslie, London.
7118. Device for Securing Scarf Pins, W. Johnson, jun., London.
7119. Brake for Mail-carts, &c., H. E. Richards, London.
7120. Governing Gear for Engines, C. H. Benton, Leeds.
7121. Making Shades for Gas Lights, A. F. Davies, London.
7122. Drilling and Tapping Pipes, W. Deighton, Harrogate.
7123. Working Metallic Sulphides, A. von Siemens, London.
7124. Ammonia, O. Imray.—(*La Société Christiania Minekompani, Norway.*)
7125. Carrier or Support for Cycles, F. W. Gunton, London,
7126. Brake Gear for Velocipedes, R. P. Moncrieff, London.
7127. Shuttle Guards, S. Hopkinson and T. Leach, London.
7128. Bobbins, G. Paley and J. A. Sutcliffe, London.
7129. Slack Adjuster, R. J. Nicholson.—(*T. E. Nicholson, United States.*)
7130. Assisting Propulsion of Cycles, L. Scoffield, London.
7131. Drying and Conditioning Cops, J. Brandwood, London.
7132. Curative or Antiseptic Compound, T. Hawkes, London.
7133. Cycling Skirts, M. Redhouse, London.
7134. Billiard and Bagatelle Cues, R. F. Jackson, London.
7135. Plate Rack, C. W. Spong, London.
7136. Copying Press, I. Rheinberg, London.
7137. Shaft Bearing, W. P. Thompson.—(*M. del Espino, India.*)
7138. Game for Parlour Tables, H. Mansergh, Liverpool.
7139. Closing Doors, J. Scheibe, Manchester.
7140. Driving Clocks by Electricity, A. Joyce, Liverpool.
7141. Picture Frames and the like, N. Myrstedt, London.
7142. Springs for Spring Mattresses, H. G. Semadeni, London.
7143. Holders for Billiard Chalks, &c., G. Hayes, London.
7144. Velocipedes, R. Kolbaba and H. Gliser, London.
7145. Hair Ornament, E. Murrle, London.
7146. Ornament for Ties and Scarves, E. Murrle, London.
7147. Gas Engines, P. Auriol, London.
7148. Ventilating Sewers, E. Holmes, London.
7149. Wire Fences, W. A. Badger and J. R. Smith, London.
7150 Golf Clubs, W. Hillman, London.
7151. Automatic Switches, F. H. Nalder, C. W. S. Crawley, and A. Soames, London.
7152. Ornamental Designs on Wood, C. Guattari, London.
7153. Cryptographic Instruments, R. Harte, London.
7154. Cycle Brakes, A. J. Haas, London.
7155. Tires of Wheels for Cycles, R. Corsham, London.
7156. Otter Boards for Trawling, &c., J. Inches, London.
7157 Cooking Stoves, A. J. Boult.—(*F. H. Buzzacott, United States.*)
7158. Frame Joints, C. T. Crowden, London.
7159. Incandescent Gas Burners, E. Attenborough, London.
7160. Steam Hammer Valves, T. Pattinson and T. Slater, London.
7161. Electric Light Fittings, F. A. Chapman, London.
7162. Secondary Batteries, A. J. Boult.—(*J. Julien, Belgium.*)
7163. Motive-power Engines, R. and C. E. Johnson, London.
7164. Cycles, G. C. Marks.—(*E. Leboucher and L. Dutheil, France.*)
7165. Bottle Brushes, A. J. Boult.—(*C. M. Higgins, United States.*)
7166. Electric Fire Alarms, M. A. Shanahan, London.
7167. Can Openers, J. M. Keen, London.
7168. Cycle Attachment, G. W. Aldrich, London.
7169. Pendulums of Clocks, T. Zee and I. Hwang, China.

2nd April, 1896.

7170. Constructing Metallic Brushes, W. G. Gass, near Bolton.
7171. Loom Shuttles, W. N. Brown and the Belfast Flax Spinning and Weaving Co., Larne.
7172. Photographic Apparatus, &c., F. Townsend, London.
7173. Mathematical Appliance, H. Creegan and G. H. Stuart, Chester.
7174. Heating by Electricity, J. C. Green, Manitoba, Canada.
7175. Boot and Shoe Lasts, J. W. Phillips, London.
7176. Cabinet for Storing Music, M. Robinson, Winchester.
7177. Stoppering of Bottles, G. Davis, Birmingham.
7178. Heating of Shafting Bearings, J. Black, Liverpool.
7179. Toy, J. H. C. Boig, Liverpool.
7180. Printers' Blankets, J. Walker and J. Strang, Manchester.
7181. Shuttle Picking Appliances, W. Thompson and J. Mather, Halifax.
7182. Bedsteads, J. A. Crane, Handsworth.
7183. Folding Cardboard Boxes, M. Grünbaum, Berlin.
7184. Driving Band for Cycles, P. Erbrecht, Berlin.
7185. Casting Box, R. H. H. Baird and I. Hall, Glasgow.
7186. Attached Trousers Clip, R. Blacklock, Sunderland.
7187. Moistening Slivers, &c., J. T. Pearson, Burnley.
7188. Heating Water, J. Marcroft and C. Heap, Yorkshire.
7189. Printing, W. J. Cummins, Newcastle-on-Tyne.
7190. Target Frame, G. T. Cooper, Aldershot.
7191. Wire Puzzle, A. H. Hughes, Wrexham.
7192. Extension Woven Wire Mattress, J. Sawtell, Wiltshire.
7193. Apparatus for Lowering Weights, J. Swalwell, Newport.
7194. Oil Motor Engines, J. Southall, Worcester.
7195. Dynamos, S. Z. de Ferranti, London.
7196. Overwinding at Pits and Mines, J. T. Calow, Sheffield.
7197. Window Blinds, J. Jessop, Sheffield.
7198. Brick or Tile Die, G. Viggars, Newcastle.
7199. Corks, J. L. Seymour, Essex.
7200. Lamps adapted to Burn Vapour, J. T. Armstrong, London.
7201. Sheets of Paper, W. Kendrick, West Cowes.
7202. Looms, J. Mawdsley and G. Bateman, Manchester.
7203. Controlling Nozzle for Fire Appliances, J. Stone, Chester.
7204. Making Heels for Boots, J. V. Collier, Birmingham.
7205. Marking at Target Practice, T. B. Ralstone, Glasgow.
7206. "See-kwik," H. E. Ives and H. Neil, Halesworth, Suffolk.
7207. Detachable Mud Guard for Cycles, J. A. Phillips, Coventry.
7208. Lace Machines, F. Key and N. Guildford, Nottingham.
7209. Hydraulic Pumps, R. Howarth, London.
7210. Securing Duplicate Copy-books, F. G. Fender, London.
7211. Lay Figures, J. F. and A. Gems, Cobham, Surrey.
7212. Cans, Jugs, &c., W. Melville and H. Buddenborg, London.
7213. Domestic Fireplaces, J. Howarth, London.
7214. Key and Handle, A. G. H. Schröder, Birmingham.
7215. Hermetically-closing Jug, A. Heinemann, London.
7216. Golf Clubs, W. M. Bryson, London.
7217. Apparatus for Counting, F. A. Mills, jun., London.
7218. Envelopes, E. W. Walsh and R. P. Edwards, London.
7219. A New Carrying Clip or Holder, A. Fry, London.
7220. Rendering Ships Buoyant, E. G. Taylor, London.
7221. Apparatus for Corrugating Tubes, I. Rees, London.
7222. Manufacturing Tubes, A. S. Elmore.—(*J. O. S. Elmore, India.*)
7223. Flower Holders, J. Lightwood, Staffs.
7224. Rug or Mat Making Machines, A. Palmer, Ipswich.
7225. Foot Rests, F. Kollmorgen, London.
7226. Gas Enriching Apparatus, G. G. Schroeder, London.
7227. Ashlar Block for Walling, &c., C. Wall, London.
7228. Cigar and Cigarette Holder, J. Fitchie, London.
7229. Velocipedes, P. T. Godsal, London.
7230. Cleaning Pens, J. Davidson and D. F. Basden, London.
7231. Manufacture of Shaping Tools, A. Paul, London.
7232. Speed Gear for Velocipedes, &c., A. Tingle, London.
7233. Incandescent Gas Lamps, J. F. Duke, London.
7234. Manufacture of Xylonite, The British Xylonite Co., and S. W. Brooke, London.
7235. Grain Chutes, H. E. Gates, London.
7236. Sachets, O. S. Dean, London.
7237. Fire Alarms I. T. Bomar, London.
7238. Production of Artificial Planums, K. Mayer, London.
7239. Protectors for Boots, W. and J. Beeton and J. Wardall, London.
7240. Lever Bottle Stoppers, C. H. Brown, London.
7241. Magic-lantern Projection Apparatus, E. Smith, London.
7242. Method of Generating Acetylene, W. C. Clarke, London.
7243. Method of Generating Gas, W. C. Clarke, London.
7244. Thrashing Machines, C. A. Teleki, London.
7245. Playing Cards, C. H. Jones, London.
7246. Guns, H. F. Phillips, London.
7247. Polishers, H. H. Leigh.—(*Guitermann, Rosenfeld, and Co. United States.*)
7248. Machine for Filling Bottles, J. G. Fauvel, London.
7249. Parquet of Inlaid Flooring, J. G. Dietzch, London.
7250. Pumps, J. E. Bousfield.—(*La Société des Procédés Desgoffe et de Georges, France.*)
7251. Distilling Apparatus, L. M. G. Delaunay-Belleville, London.

7334. Locking Bicycles, &c., H. van der Weyde, London.
7335. Evaporimeter, P. S. U. Pickering, London.
7336. Hermetically Closing Receptacles, J. Schafer, London.
7337. Method of Treating Bagasse, J. Périchon, London.
7338. Book-markers, C. J. Letts, London.
7339. Fumigating Composition, H. H. Lake.—(*Société Anonyme de la Fabrique de Carton de Grandson et d'éclairage électrique, Switzerland.*)
7340. Bottle Stoppers, J. B. Tauveron, London.
7341. Ball Slings, J. Waldmann, London.

7th April, 1896.

7342. Separable Bookcase, O. H. L. Wernicke, Manchester.
7343. Dust Trap Attachment, &c., J. Toppin, Bristol.
7344. Cigar Holders, W. R. Oliver, London.
7345. Bosses of Cycle Saddles, J. B. Brooks, Birmingham.
7346. Apparatus for Propelling Ships, A. G. Ramage, Leith.
7347. Awning Stanchions for Use on Ships, W. Bell, Glasgow.
7348. Tablets for Advertisements, T. Corser, Manchester.
7349. Gear Chains, J. Walker, Derby.
7350. Chimney Cowls, J. M. Macaulay, Glasgow.
7351. Obtaining Motive Power, &c., J. Newton, London.
7352. Means for Consuming Smoke, T. Brook, Huddersfield.
7353. Supporting Gas Burners, T. Redman, Bradford.
7354. Cocks, W. D. Ferguson, Belfast.
7355. Attaching Brackets to Upright Standards, G. Gibbon, London.
7356. Saws, D. Doyle, Cork.
7357. Hair Pins, G. M. Davies, Cardiff.
7358. Process of Nickel Plating, H. L. Haas, London.
7359. Car Couplers, J. Johnson.—(*C. A. Tower, United States.*)
7360. Shuttles, W. H. Inslee.—(*The Singer Manufacturing Co., United States.*)
7361. Machines for Expelling Water, M. S. Ayau, Glasgow.
7362. Steam Generators, J. Entwisle.—(*E. T. Sederholm, United States.*)
7363. Gas Burner Fittings, T. Pursey, Edinburgh.
7364. Wheel for Road Vehicles, R. W. Frost, Staffordshire.
7365. Self-adjusting Slide for Cameras, B. Moodie, Arbroath,
7366. Trap for Killing Game, J. McLaren, Dumbarton.
7367. Hoods for Incandescent Gas Lamps, H. Hill, Nottingham.
7368. Cuff Fastening and Retaining Stud, J. Cleland, Down.
7369. Driving Gear for Cycles, A. W. and S. Farnsworth, Derby.
7370. Syphons, J. Davey, Hitchin.
7371. Plates for Fixing in Letter-boxes, A. and C. Merriman, Redditch.
7372. Brackets for Curtain Rods, A. Newman, Birmingham.
7373. Fishing Apparatus, C. Willson and T. C. Robinson, Grimsby.
7374. Brush, J. C. Meyers, Dublin.
7375. Carpet Sweeping Machines, J. Gutmann, London.
7376. Liquid Heaters, M. G. Wilder, London.
7377. Gas Motors, W. H. Casey and A. F. Woodman, Exeter.
7378. Controlling Cages in Mines, J. H. Townsend and W. Dixon, London.
7379. Extracting Oil from Seeds, W. R. Harrison and E. Stephenson, London.
7380. Beer Engine Spouts, J. Griffin and W. E. C. Pinchbeck, London.
7381. Metallic Belting, W. Gibson and W. H. Palmer, London.
7382. Water-closets, D. S. Wallace, London.
7383. Producing Metal Tubes, &c., T. S. James, London.
7384. Waterways, C. N. Dutton, London.
7385. Horseshoes, J. B. Gillespie, London.
7386. Butter Box, A. Hart and C. A. Bramwell, London.
7387. Glove Fastener, G. H. Moller, London.
7388. Fire Extinguishers, H. H. Lake.—(*T. J. Vail, United States.*)
7389. Telephone Transmitters, W. L. Wilheim and B. J. Tillman, London.
7390. Musical Instruments, H. H. Lake.—(*J. E. Maynadier, United States.*)
7391. Wheels of Cycles, J. Morrison and W. T. Dale, London.
7392. Solder Plates or Tablets, J. J. Laffitte, London.
7393. Linoleum, W. P. Thompson.—(*T. Potter, Sons, and Co.,*——)
7394. Clasp Knives, W. P. Thompson.—(*A. K. Brauer, United States.*)
7395. Knitting Machines, J. Bennor, Liverpool.
7396. Box Iron, F. E. Hunter, Liverpool.
7397. Protecting Mantles of Burners, L. Teichmann and E. Hopkins, London.
7398. Paper and Cardboard Boxes, H. C. Norman, London.
7399. Making Justified Lines of Type, A. J. Boult.—(*The Lanston Monotype Machine Company, United States.*)
7400. Steering Gears for Vessels, C. E. Bergman, London.
7401. Cycle Handles, J. McRae, London.
7402. Dust-excluding Ring for Cycle Bearings, J. McRae, London.
7403. Type-writing Machines, B. C. Stickney, London.
7404. Sorting Machines, C. G. Poulson, London.
7405. Treatment of Vegetable Fibres, C. Efros, London.
7406. Dress Protector, A. R. Gahagan, London.
7407. Screw and Nail, C. Grundy, London.
7408. Transfer Pictures, Grimme and Hempel, London.
7409. Cork Pullers, E. Walker, London.
7410. Starch and Dextrine Combinations, A. Classen, London.
7411. Wash-boards, J. T. Sargent, London.
7412. Money Tills, F. O. Jerram and A. E. Jerram, London.
7413. Decorative Embossing, A. C. A. Rottmann and A. Silver, London.
7414. Screw-cutting Stocks and Dies, H. Reisiger, London.
7415. Controlling Apparatus for Dyeing, W. E. Curtis, London.
7416. Type-writing Machines, A. W. Steiger, London.
7417. Sole-laying Machines, &c., J. G. Lorrain.—(*The Goodyear Shoe Machinery Company, United States.*)
7418. Boots, W. Owen, London.
7419. Sack Holders, J. Marshall, London.
7420. Railway Couplings, S S. Bromhead.—(*The Society for the Exploitation of the Danischewsky Patents, Switzerland.*)
7421. Pneumatic Hub for Wheels, H. C. Bevan, London.
7422. Making Steel or Alloy of Iron, R. A. Hadfield, London.

8th April, 1896.

7423. Automatic Cork Extractors, A. Bodding, London.
7424. Extraction of Gold from Ores, J. B. Torres, London.
7425. Neckties, T. Day, Wolverhampton.
7426. Holding and Releasing Cords, J. S. Orton, Birmingham.
7427. Valves for Pneumatic Tires, W. Brookes, Manchester.
7428. Regulating Pumping Engines, J. Hodson and H. S. Clement, Glasgow.
7429. Mantles for Incandescent Lamps, J. B. de Léry, Manchester.
7430. Loom Shuttles, W. E. Heys.—(*A. Duhamal, France.*)
7431. Ship Steering Mechanism, R. Boutflour, Stockton-on-Tees.
7432. Cycle Attachment, W. Brice, Bristol.
7433. Folding Seats, J. D. Richardson and F. H. Young, Birmingham.
7434. Stay Busks, W. Wright, Sheffield.
7435. Oil Motors, G. Johnston, Glasgow.
7436. Blast Furnaces, W. Gibbings, Widnes.
7437. Fastening Braces, G. Crees, Ross.
7438. Incandescent Gas Burners, E. H. C. Oehlmann, Glasgow.
7439. Pockets for Garments, P. Hossfeld and S. Beer, Glasgow.
7440. Tracing Pin, A. P. R. Willis, Leatherhead.
7441. Driving Gear for Cycles, &c., J. W. Duncan, London.
7442. Tire, L. Schramm, London.
7443. Musical Instruments, G. Bortmann and A. Keller, London.
7444. Preventing Re-filling of Bottles, J. Lang, London.
7445. Ventilating, P. Lawrence.—(*T. A. Richards, United States.*)
7446. Exhaust Fans, P. Lawrence.—(*T. A. Richards, United States.*)
7447. Recovery of Zinc from Ores, H. R. Angel, London.
7448. Tripod Stands, H. J., A. S., and G. A. Spratt, London.
7449. Dry-docking Ships, S. Dure, London.
7450. Equipments, T. H. Cothill.—(*P. Lewis, Canada.*)
7451. Portable Water Bottles, T. H. Cothill.—(*P. Lewis, Canada.*)
7452. Making Iron-cutting Saws, E. Graf, Aix-la-Chapelle.
7453. Bicycles, H. F. Hill, Nottingham.
7454. Motor Engines for Auto-cars, A. Berrenberg, London.
7455. Steam Turbines, R. Hewson and Messrs. Whyte and De Rome, London.
7456. Arm Rest for Book-keepers, C. S. Gilman, London.
7457. Moulding Machines, W. P. Thompson.—(*C. Cristadoro, United States.*)
7458. Teaching Music, J. H. and E. M. Hendrey, London.
7459. Toilet Tables, Wardrobes, &c., J. Porter, London.
7460. Toilet Tables, Wardrobes, &c., J. Porter, London.
7461. Window Attachment, C. H. Clarke, London.
7462. Photographically Printing Strips, B. Acres, London.
7463. Incandescent Gas Lighting, L. Denayrouze, London.
7464. Treating Bay Salt, A. MacNab, London.
7465. Sinking Caissons, C. M. Johnson and S. W. Parker, London.
7466. Spindle Mechanism of Locks, &c., T. Jones, London.
7467. Brushes, J. J. Ashburner, London.
7468. Automatic Guns, H. S. Maxim, London.
7469. Systems for Preserving Paid Checks, T. M. Hurley, London.
7470. Ironing Boards, T. J. Sutton and G. J. Palmer, London.
7471. Supports for Pictures, &c., E. A. Swineford, London.
7472. Railway Spikes, R. W. Beidleman, London.
7473. Steam Valves for Steam Cylinders, M. Berger, London.
7474. Spring Grab Hooks, E. Dobbins, London.
7475. Shallow Water Signals for Vessels, H. H. Franklin, London.
7476. Car Fenders, F. J. Graf, London.
7477. Incandescence Gas Burners, P. Schroedter, London.
7478. Stop Valves, &c., A. J. Boult.—(*M. Groignard, France.*)
7479. Variable Speed Gear, J. W. Hall, London.
7480. Preservation of Organic Substances, A. J. Boult.—(*F. Fritzsche and Co., Germany.*)
7481. Dress Fastenings, H. Fuller, London.

9th April, 1896.

7482. Trunk, C. Manners, London.
7483. Fanlight and Clothes-line Fastener, &c., G. Chambers, London.
7484. Electric Meters, Evershed and Vignoles, Ltd., and S. Evershed, London.
7485. Oil Cups for Machines, A. Hitchon, Accrington.
7486. Nautical Instruments, J. Morton, Newcastle-on-Tyne.
7487. Oil Can, R. Hopper, Newcastle-on-Tyne.
7488. Reversible Sliding Window, G. Vincent, London.
7489. Combined Bottle and Measure, J. Renwick, Manchester.
7490. Controlling Railway Carriage Doors, J. Robinson, Liverpool.
7491. Filter, L. Classey, Limerick Junction.
7492. Combination Pie-crust Support, &c., R. H. Rowland, Suffolk.
7493. Opening, &c., Water-tight Doors, J. Carmichael, Glasgow.
7494. Manufacture of Drying Horses, D. K. Tullis, Glasgow.
7495. Sliding Window Sash Frames, T. F. Gaunt, Nottingham.
7496. Apparatus for Planing Boards, J. Barr, Renfrewshire.
7497. Gauge for Shoe-nailing Machines, J. Bootham, Manchester.
7498. Displaying Words, &c., E. Sandow, Manchester.
7499. Cotton Waste Breakers, J. Lobley, Manchester.

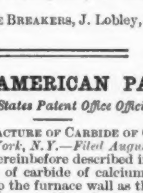
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

552,890. Manufacture of Carbide of Calcium, *W. C. Clarke, New York, N.Y.—Filed August, 24th,* 1895.

Claim.—(1) The hereinbefore described improvement in the manufacture of carbide of calcium, which consists in building up the furnace wall as the formation of the carbide progresses, adding fresh charges of the material to be treated as the wall is built up and keeping the lower end of the upper electrode at all times near the upper edge of the furnace wall. (2) The hereinbefore described improvement in the manufacture of carbide of calcium, which consists in forming around the lower of two vertically disposed electrodes an enclosure greater in diameter than such electrode, charging into such enclosure the material to be treated and subjecting it to a decomposing temperature by means of an electric current between such electrodes, adding fresh charges of material and separating the electrodes as required to continue the operation and building up the wall of the enclosure as required to contain the material added.

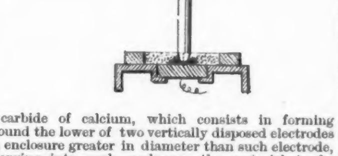
552,890



552,907. Tandem Attachment for Bicycles, *M. Jakobson, New York, N.Y.—Filed March 29th,* 1895.

Claim.—A three-wheeled tandem cycle, consisting of an ordinary safety bicycle, a tandem attachment having a single wheel and consisting of an ordinary frame provided with a seat and handle bar, a forwardly extending brace at the upper part of the auxiliary frame, a forwardly extending fork at the lower part of the frame, a pedal shaft and pedals, sprocket mechanism between the pedal shaft and the wheel of the tandem attachment, and means for detachably connecting the brace and fork of the tandem attachment with the rear fork of the main bicycle, substantially as set forth.

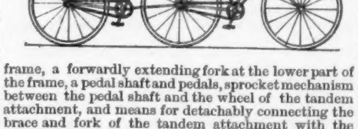
552,907



553,097. Hurdy-Gurdy Water Wheel, *F. M. Bookwalter, Springfield, Ohio.—Filed February 7th,* 1895.

Claim.—In a hurdy-gurdy water wheel, the combination with a horizontal wheel proper having buckets which discharge laterally, of one or more nozzles in a lower plane than the buckets and discharging into them.

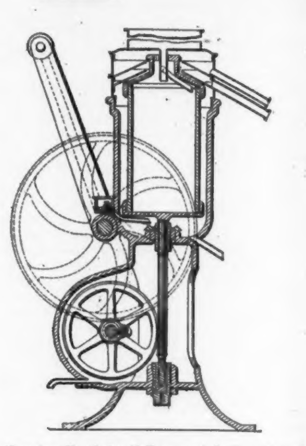
553,097



553,223. Centrifugal Creamer, *O. Anderson, Newark, N.J.—Filed May, 6th,* 1895.

Claim.—(1) The combination with the centrifugal bowl *a*, threaded shaft *b*, worm wheel *e*, shaft *f*, and nut *k*, provided with clutch teeth, of the clutching cog-wheel *h*, spring *l*, speeding wheel *m*, and means for turning the same, all said parts being arranged and combined, substantially as set forth. (2) The combination with the centrifugal bowl *a*, bowl carrying shaft *b*, shaft *f*, and train of means for transmitting power from one of said shafts to the other, of the clutch part *k*, fixed to said shaft *f*, and having teeth, a sliding cog-wheel *h* having co-operating teeth, a spring, a speeding wheel *m*, and means for transmitting power thereto, all substantially as set forth. (3) The combination with the centrifugal bowl *a*, shaft *b*, shaft *f*, and train of means for transmitting power from one shaft to the other, of the clutch part *k*, fixed to said shaft *f*, and having under-cut teeth, a sliding cog-wheel having correspondingly under-cut teeth, a spring, a speeding wheel and means for transmitting power thereto, all substantially as set forth. (4) The combination with the case *c*, centrifugal bowl *a*, bowl carrying shaft *b*, and means for rotating said shaft, of a supplemental piece *b′*, a cup-shaped adjustable chair or seat *p*, stepped interiorly as described, and a hardened and cushioned piece within said cup-shaped seat serving as a bearing for said supplemental piece, substantially as set forth.

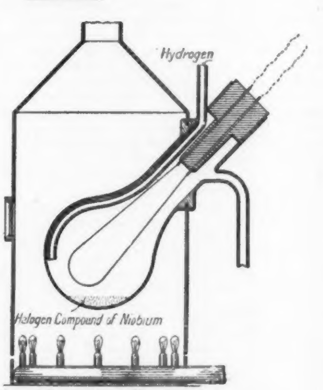
553,223.



553,296. Art of Manufacturing Electrical Incandescing Conductors, *J. W. Aylsworth, Newark, N.J.—Filed July 27th,* 1894.

Claim.—(1) The described method or process of depositing any of the hereinbefore named refractory metals upon a surface which consists in subjecting a halogen compound of such metal to the action of heat and a reducing vapour or gas as hydrogen, and at the same time electrically heating the surface upon which the metal is to be deposited. (2) The described method or process of constructing an incandescing conductor for an electric lamp, consisting in subjecting a halogen compound of a refractory metal and a reducing vapour or gas to heat and simultaneously passing a sufficient current of electricity through a conducting base or support to effect a deposit of the metal of the halogen compound upon said base or support. (3) The described method or process of preparing incandescing electrical conductors of highly refractory metals, consisting in subjecting a halogen compound of the metal to be used to the effects of heat and a reducing gas and simultaneously giving to a conducting base filament or support surrounded by said gas and the vapours emanating from the halogen compound an incandescence sufficient to effect a deposit of the metal of the compound upon the base filament or support. (4) The described method or process of producing or preparing incandescing filaments or wires from refractory metals as niobium, consisting in subjecting a halogen compound of the metal to the united influence of heat and a reducing gas and simultaneously giving to a conducting filament or base surrounded by the gas and the vapour of the halogen compound an incandescence sufficient to cause the metal of the halogen compound to be deposited thereon.

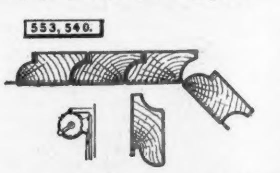
553,296.



553,540. Fire-proof Shutter, *F. E. Pollard, Worcester, Mass.—Filed March 30th,* 1894.

Claim.—(1) In a fire-proof shutter, the combination of a series of shells in the form of strips or leaves extending transversely across the shutter with their edges overlapping, a heat non-conducting material enclosed in said shells, said shells being arranged together at their abutting edges, substantially as described. (2) In a fire-proof shutter, the combination of a series of shells in the form of strips, or leaves, extending transversely across the shutter with their edges overlapping, said shells being united at their edges by a flexible connection, substantially as described. (3) In a fire-proof shutter, the combination of a series of shells formed of sheet metal and having a series of slits, or openings J upon opposite corners and a flexible metallic band extending through said slits, or openings, whereby said shells are united, substantially as described.

553,540.



THE GOHNA LANDSLIP AND FLOOD.

IT will be remembered that a mighty landslip occurred in the end of the year 1893 in one of the outliers of the Himalaya Mountains, on the north-west frontier of India. This, by blocking up the Birahi Gunga, one of the tributaries of the river Ganges, led to the formation of a large lake whose waters threatened, as soon as they had accumulated sufficiently to overtop the obstruction caused by the landslip, to overwhelm the valley below. The story is now two years old, yet so slowly do the official mills grind that up to the present—as we believe—no authoritative report has been presented to the public of the occurrence, and the measures adopted to meet the catastrophe. The first complete account of the event has come to us in a paper read before the Imperial Institute by the Secretary of the Indian Section, in the absence of its author, Mr. J. H. Glass, C.I.E., a chief engineer of the Bengal Public Works.

Seldom has the paternal care with which the Government of our Indian Empire safeguards its subjects been more clearly exemplified than in the case before us, when an enormous volume of water suddenly hurled itself along the river valley at the dead of night, raising the river in many places more than 100ft. above the level of ordinary flood, yet without causing, so far as is known, the loss of a single human life.

Gohna, where the landslip happened, is a small village of 200 souls situated in latitude 30 deg. 22 min. 18 sec. N., and longitude 79 deg. 31 min. 60 sec. E. in Garhwal, in the N.W. Province of British India. It lies on the right bank of the Birahi Ganga, a tributary of the Alaknanda river, which, after its junction with the Bhagirathi at Deopryag, sixty-two miles above Hardwar, is henceforth known as the Ganges.

At Hardwar, 150 miles below Gohna, the river passes through the last gorge in the hills and debouches on the plains of Northern India. Between these two places its course lies in narrow ravines, and this part of the river, famous as the resort of Hindoo pilgrims, is along its margin studded with sacred stations and holy shrines, between which streams of devotees pass to and fro.

The valley in general is sparsely inhabited, Srinagar, with a population of 2000, being the largest town, and the cultivation scant; yet in case of an unexpected release of the accumulated waters, owing to the presence of the pilgrims and the surrounding circumstances, the loss of life might have been immense, and the destruction of property would have been enormous if sufficient and timely precautionary measures had not been adopted.

Just below Hardwar, at Maiapur, on the river, are situated the headworks of the great Ganges Canal, and serious injury to this work would have caused enormous loss to the Government and the agricultural community, as well as doing incalculable damage to the country below, over which so large an area of cultivation with its revenue is dependent on irrigation by the canal.

The problem, therefore, that the Government set before itself in dealing with the catastrophe was to prevent, if possible, all loss of life among the pilgrims and villagers on the road leading to the shrines and in the valley, and to save from destruction, as much as could be done, all public and private property within the probable range of the avalanche of waters that was expected to result from the bursting of the dam formed at Gohna.

In connection with the measures to be adopted, the first and most important point to decide on was the period the lake would take to fill and overflow. In the nature of the case the data on which to base calculations were most insufficient; yet it speaks well for the care and judgment of the engineers that, when the surveys and contours of the basin were effected, and the rainfall and snowfall during the year on the catchment duly considered, the forecast of the date on which the barrier would be overtopped was only ten days earlier than the date—the 25th of August—on which the event acually occurred. The 15th of August was thus the date fixed as that by which all preparations for the overflow should be complete.

The first and chief precautionary measure was the construction of a telegraph line between Gohna and Hardwar, following the river course, and having stations at all important points along the line. It was decided that there should be in all ten telegraph signalling stations, selected with regard to their importance as camps or halting places for the pilgrims on their journey along the river. This provision, besides relieving the suspense both of the public and officials at the most critical periods, and facilitating operations generally, avoided the necessity that would have otherwise existed of closing the road along the valley used by the pilgrims; to have stopped all traffic would have inflicted great hardship on the people and been an extremely unpopular measure. This road admits only of foot traffic, but the Government has spent considerable sums of money on its improvement. Suspension bridges have been built, precipitous paths eased off and rendered safe, and bazaars established along it to provide the pilgrims with supplies. It was decided to dismantle the permanent suspension bridges along the road, and replace them by temporary rope structures, and this was done except in two cases, where at the special request of the local authorities, two bridges were left, which, in their opinion, were safely beyond any flood likely to occur. As a result, these bridges were completely wrecked.

Further, it was arranged to erect masonry signal pillars in the valley at a level of 200ft. above ordinary flood from Gohna to Srinagar, and at 100ft. above the same datum in the valley below Srinagar. These pillars were 4ft. square and 6ft. high, and were erected at all villages and camping grounds; and elsewhere at intervals of half a-mile; they marked a limit below which it would be unsafe for people and their property to remain after warning of the approach of the flood had been issued.

So much for the precautions above Hardwar; below it the safety of the headworks of the Ganges Canal demanded earnest attention, as a heavy flood bursting into the canal might not only carry the headworks away, but also seriously injure the great torrent works and falls as far as Roorkee. The following protection works were therefore carried out:—A massive crate dam filled with heavy boulders was constructed between the river weir and the canal head, with embankments leading to the rising ground to prevent the headworks from being outflanked by the flood. The canal head-gates were strengthened to make them better able to resist the exceptional head of water against them. Subsidiary boulder "bunds," or banks, were erected to prevent outflanking, and other minor provisions adopted. In the low lands, in the ninth mile of the canal, and immediately above the embankment of the Solani Aqueduct in the sixteenth mile, the canal banks were lowered so as to provide temporary escapes, which would relieve the canal and thus possibly aid in saving the great masonry works on the canal lower down at Roorkee, in case of the flood bursting into it at the headworks.

According to native reports—for no European, scientific or otherwise, visited the site till some time afterwards—what happened at Gohna was this:—In September, 1893, an enormous mass of material from the mountain of Maithana, on the right bank of the Bhirai Gunga, slipped into the river; and again in October of the same year there was another great fall. The mountain itself is 11,000ft. high, and the part of it from which the mass fell is 4000ft. above the bed of the stream. The material consisting of earth and rock came down with a deafening noise, and the neighbourhood for miles around was enveloped in clouds of dust, which whitened ths ground and the branches of trees like a fall of snow. The magnitude of the barrier formed across the stream by the landslip may be judged by the following rough measurements: The height was 900ft., the length measured across the gorge was 3000ft. along the top, and 600ft. at the bottom; and in cross section it was 2000ft. at the top and 11,000ft. at the base, so that the side slopes must have been about one in five.

It was calculated from the contoured map of the valley, prepared by Lieut. Crookshank, R.E., the officer in charge of the operations, that the area of the lake which would be formed, when the water was at the level of the top of the dam, would be thirty-seven millions of square feet, or say, 1½ square miles and its contents roughly estimated would be 16,650 millions of cubic feet. Its catchment was about ninety square miles, and was bounded on the north by a snow-clad ridge of the Himalayas rising to altitudes of 21,200ft. above the sea level.

The longitudinal bed fall of the Birahi Gunga is about 250ft. per mile at Gohna, and its course bends nearly at a right angle immediately below the site of the slip. It runs entirely through ravines with steep precipitous sides, grass covered at the base, and higher up clothed with oaks, firs, and rhododendrons.

The phenomenon of the landslip was adjudicated by an expert of the geological department to have been due to a combination of causes; such, for instance, as the alteration of the chemical condition of the substance of the strata, the solution of substance and reduction of friction among the beds by the action of water, all of which tended to prepare the mass for motion, while the expansion resulting from atmospheric effect, with changes of temperature seconded by hydrostatic pressure, may most probably have caused an impulse in the direction of least resistance, and thus produced the slip. An interesting report on the subject is published in the records of the Geological Survey of India, in which the author of the paper concludes with the following words:—"It may be of interest to remind the general reader of the fact that the folding of the Himalayan range having continued to times geologically recent, if not still in action, there has resulted a condition of strain frequently manifesting and relieving itself by earthquakes; and of steep slopes with rushing torrents, frequently resulting in landslips. When subsequently the inequalities of level have been sufficiently reduced by denudation, the slope will be more stable, rivers less violent, and the scenery tamer—a condition of affairs exemplified by the more geologically old-fashioned peninsular portion of India. Water, the great agent of denudation, has by its chemical and physical action been the cause of the landslip at Gohna."

The periodical rains commenced early in June, but before the end of July all arrangements were completed. The waters of the lake had for some time back been rising rapidly, owing to heavy rain and the melting of the snow on the mountains, and on the 9th there was a downpour on the dam itself. On the 10th of August the first symptoms of the approaching collapse developed themselves in the shape of a serious slip of the down stream face of the dam, leaving an almost perpendicular scarp of some 400ft. high. The section thus exposed showed a layer of stones at the top resting, so far as could be seen, on pulverised rock.

The first note of warning was in consequence of this slip telegraphed on the 11th August down the river to all concerned. Percolation became very copious, and a considerable stream, about 300 cubic feet per second, was to be seen running over the boulders of the former river bed laid bare by the slip of the dam. The water level was at this time within 50ft. of the top of the dam, and it was estimated that in fifteen days the overflow would take place.

On the 22nd, Lieutenant Crookshank essayed to hasten events by making a small cut through the crest of the dam, and thus hoped to produce the overflow early in the morning of the 24th, it being important that the flood should take place in the daytime; but owing to increased percolation and diminished rainfall in the interval, the lake rose more slowly than expected, and the first overflow did not take place till 6.35 o'clock on the morning of the 25th of August.

At first the destructive action of the water was slight, but before long the immensely increased percolation caused a rapid cutting back of the dam, and at 2 p.m. a message was despatched down the line announcing that the flood might be expected during the night. Unfortunately, at this time a thick mist had descended on the scene, and all the provisions for observing the subsidence of the water in the lake, and the action of the flood when passing over the dam, in the shape of masonry bench marks, were rendered nearly useless. These bench marks were placed on the top of the down stream face of the dam, at 50ft. apart, and numbered consecutively in large figures so as to be plainly observable from the sides of the valley. Their object was to allow of a reliable record being made of the way in which the water, when discharging itself, cut away the material of the dam. The rate at which the water of the lake subsided was to have been recorded every hour by observations of other bench marks placed on the hill side, and as the valley had been carefully contoured at verticals of 1ft., the outflow could have been easily calculated. In addition to the above arrangements at the lake, other bench marks were placed at observing stations down the river. By numbers on these the rise of the floods passing could be accurately observed by daylight, and at night lighted lanterns were placed on them at vertical intervals of 10ft.; the lights, as the waters rose, were extinguished, and thus the flood heights could be estimated.

At 11.30 p.m. a loud crash was heard, and in spite of the mist and rain, the air was filled with a fine dust which rose from the site, and so far as could be ascertained, the dam was completely breached, a fact at once telegraphed down the valley. The rush of water was very great, but owing to the atmospheric conditions it was impossible to gauge the discharge. At five in the morning, although the valley was full of mist and the light very unsatisfactory, it became evident that a considerable fall had taken place in the level of the lake, and the authorities at Hardwar were warned to expect a great flood. It was calculated that 10,000 millions of cubic feet of water had been discharged in the space of 4½ hours, as the lake had fallen 390ft. At the gorge immediately below the dam, the flood rose to 260ft. over its ordinary level. The valley was filled up with huge blocks; and the bed of the river was raised some 234ft., by a substantial weir with a long gentle slope stretching far down the valley. At thirteen miles down, the river bed was raised 50ft. by the *débris* deposited, and the flood reached a height of 160ft. above its ordinary level.

All down the valley, for fifty odd miles, the flood rose from 113ft. to 140ft., causing serious damage. Even at Shrinugar, seventy-two miles from the landslip, the flood, which was first observed at 3.25 a.m., attained a maximum height of 42ft. above ordinary flood level. Here the damage done was great. The entire town, with the Rajah's palace and the public buildings, were destroyed, and a thick layer of stones, sand and mud, deposited over the area. Several small villages in the valley, which here opens out into a large amphitheatre of between three and four miles long and one mile wide, were completely swept away. The flood reached Hardwar, 150 miles from Gohna, at 8.45 a.m. on the 26th August, and obtained a maximum height of 11ft. above the ordinary flood level. Fortunately, the main river was low at the time—lower, in fact, than at any time during the previous month. Had the extra Gohna flood arrived on top of one of the very heavy normal floods of the previous thirty days, the canal must have suffered grave disaster. As it was, considerable damage was done. The revetment walls at Hardwar and the marginal "band" or dam were topped, and the diversion channel breached. Four out of seven of the sluices in the Maiapur dam were put out of action by the *débris* brought down, and though the crate dam was not topped, yet some water broke into the canal through the head. In the town itself the flood is reported to have stood 6ft. deep in the main streets. The velocity of the torrent was gauged by observing the time that blocks of wood or other floating bodies took to pass between fixed points of known distances apart. By this method it was estimated that the average velocity of the flood in the upper seventy miles of its course was 26ft. per second, but in the stretch of twelve miles below Gohna it is considered that a maximum of at least 40ft. per second must have been attained.

At Srinagar a curious phenomenon occurred. Below the town the open valley contracts suddenly, at the Jakhni Gorge, and the bed is narrow and the sides precipitous. The effect of this conformation was that the flood water after spreading out at Srinagar was abruptly contracted at the gorge and a strong swirling backwater current was set up. The furious rush of this eddying water was terrifying in the darkness of night close below the observers, and many who had been securely placed in temporary shelter huts fled in terror still higher up the mountain side.

Although the greatest care was taken to keep down the expenditure, and every proposal was submitted to the strictest scrutiny, yet the total of the loss to Government and the outlay in measures for the protection of the life property of the people, the former of which formed a first consideration, amounted to Rs. 2,500,000. Of this sum the destruction of bridges and buildings down the valley as far as Hardwar may be taken as Rs. 100,000. The cost of the telegraph line and the housing of the staff engaged in the operations amounted to about Rs. 90,000, and the protection work, added to the repairs of the damage done by the flood to the Ganges Canal, is estimated at Rs. 50,000. The loss caused to private individuals has not been estimated.

The loss of life has been nil, if we except the case of the Gohna fakir and family; these perished in the slip of the dam slope on August 11th, a result due to their own fatuous obstinacy, and not necessarily a consequence of the flood. The fakir had persisted in remaining in a very dangerous position below the dam, though he had repeatedly received orders to leave it. He and his family had twice been forcibly removed; but each time they had returned, and were eventually overwhelmed in the slip, which we have described as taking place in its rear slope previous to the total failure of the dam.

One of the results of the landslip from the mountain is that a lake of considerable size has been established at Gohna. Its dimensions are about two miles long by a mile wide, and it has a maximum depth of 800ft. The large rocks and residual *débris* have been so consolidated and packed by the flood, that they now form a massive and solid dam or weir which is not likely to be disturbed, so that the lake is probably a permanent one, and Gohna may one day prove a pleasant resort from the plains below.

Naturally, while the preparations to meet the flood of 1894 were in progress, many criticisms were made on the operations in the public papers, and much advice was offered to the Government, both publicly and privately.

The chief question taken up by the influential section of the public was the advisability of cutting a channel through the dam to facilitate the escape of the water before it reached the full height of the obstruction. This proposal was set aside for the reason that the mass of water which would in any case be headed up, and must eventually cut through the upper layers of the dam, would cause a serious flood of practically the same intensity as if the dam were untouched, and because of the great expense, if not the impossibility, of making a sufficient cut within the time available. For example, a cut of, say, 50ft. deep would have still left over 700ft. of water in the lake, and have had no appreciable effect in lessening the flood; while the whole army of labourers to do the work would have had to be imported, housed, and fed in an almost inaccessible country during a season of heavy rainfall, at an estimated cost of three lakhs of rupees or more. Considerations, too, in connection with the danger at the temporary headworks, which are put up yearly at Hardwar for the purpose of supplying the Ganges Canal with water in the dry season, led Government to reject the proposal as a wasteful extravagance with no practical advantage.

Various other suggestions were rejected for different reasons, and some persons even urged that there would be no cutting back and no flood, but that the water would quietly pass over the crest of the dam and down the face of the talus, and so into the regular river channel, producing no more damage than an ordinary flood.

Other objectors urged that the velocity of twenty miles an hour, at which rate the flood was calculated to escape down the river, was exaggerated and impossible. Some ridiculed the provision of the safety pillars as an arbitrary and absurd arrangement. And the construction of the telegraph was set down as a wasteful extravagance, and the dismantling of the bridges was held to be quite unnecessary. However, the success which attended the operations sanctioned by Government was greater than could have been anticipated, and no higher testimony is possible to the efficiency of the protective measures, and to the care with which they were carried out, than that the people themselves recognise and are grateful for the consideration they have received in the precautions which were taken for their safety. We have no doubt that the recollection of the beneficent care shown by Government for the preservation of their lives and the protection of their property will remain for ever fresh in their memories. It speaks well for the administration of Sir Charles Crosthwaite, K.C.S.I., that the situation was so promptly and firmly grasped, and to prove that such has been the case, and to judge of what might have happened otherwise, we have only to compare the record of this flood with that of 1868. The latter flood was due to a similar cause, viz., the bursting of a lake, probably also formed by a landslip, at no great distance from Gohna, and it does not appear that any precautions, such as in the present instance, were taken to meet it. At that time Sir Henry Ramsay was Commissioner at Kumaaon, and in reporting the occurrence of the flood to Government, he stated that several bridges along the valley had been carried away, and that some houses, crowded at the time by pilgrims on their way, were submerged. The accumulated waters, he adds, came down so suddenly at night that there was no warning, and only a few pilgrims—most likely awakened by the noise of the rushing waters—were able to run up the hill and escape; all the others with the houses were swept away. Much animal life was lost and a considerable amount of property destroyed.

THE ENLARGEMENT OF LIVERPOOL-STREET STATION, GREAT EASTERN RAILWAY.

BRIDGE AT WORSHIP-STREET.

In carrying out the extensive works in connection with the widening of its metropolitan terminus, the Great Eastern Railway Company found it necessary to bridge over, stop up, divert, and otherwise unavoidably to interfere with several of the old streets, lanes, passages, and thoroughfares situated in the line of the new route. Among other collateral undertakings, three large over bridges were required to be built to carry Worship-street, Primrose-street, and Skinner-street, across the numerous lines of track all converging towards, and having for their common focus, Liverpool-street Station. All these three structures are on the skew, that at Worship-street, which we now intend describing and illustrating, forming an angle of 60 deg. with the line of roadway overhead. A general elevation of the bridge is shown in Fig. 1, and a plan in Fig. 2. From the former figure it will be seen that the main girders belong to what is known as the bastard type, that is, a form which is a cross between the horizontal lattice or open web girder, with parallel booms, and the bowstring. While, therefore, embodying in its design and construction the characteristics of the straight lattice, so far as the lower boom and web bracing are concerned, it trenches upon the bowstring type by the curvature of the upper boom. The vertical members shown in Fig. 1 are necessitated by practical requirements connected with the peculiar double section of the booms, which will be apparent when we proceed to treat of the details of their construction. Besides, vertical members are common to both types. Theoretically, the result of curving the upper boom of an open web girder is to increase the stresses towards the ends of both booms, while at the same time relieving the diagonal struts and ties in the web generally of a portion of the shearing stress. Practically, the effect is to impart a more graceful appearance to the contours of the structure, as in the example before us. Besides, the amount of curvature is small, and not sufficiently great to occasion much alteration in the nature of the stresses.

The span of Worship-street bridge is 73ft. on the square and 85ft. 7½in. on the skew. The height from rail level to the lowest point of the lower boom of the main girder is 14ft., and the distance from the same datum to the level of the roadway 20ft. 3in. At the centre, including cover plates, the depth from out to out is 10ft. 2in., diminishing to 7ft. 2in. at the ends over the bearings. From centre to centre the main girders are 43ft. 2in. apart, which dimension allows for a roadway 24ft., and two footpaths, each 8ft. wide respectively. The vertical members or diaphragms, which connect the two separate sections of the upper and lower booms, divide the span of the main girders into eleven bays, consisting of a pair of diagonal struts and ties riveted together at their central intersection. All the bays, except the two short ones forming the ends of the girders, are 8ft. in width, and, where the dividing diaphragms are riveted to the lower booms, the cross girders are attached. There are thirteen of these altogether, of which nine in the general plan, Fig. 2, run from one main girder to the other, and the remaining four rest partly upon girders and partly upon the abutments. A general cross section on the square, in Fig. 3, shows the double section of the upper and lower booms of the main girders, the cross girders, which are of the solid web or plate description, and a section of the side screens and supports. Over the bearings at the abutments the manner in which the bed plates and ends of both main and cross girders are arranged is indicated in Figs. 4 and 5, while Fig. 6 is a section through the line A A in Fig. 5, and shows the construction of the abutments, counterforts, and their foundation of concrete, 2ft. 3in. in thickness.

A half elevation of one of the principal girders, 97ft. 7½in. in total length, is given in Fig. 3*a*, a half sectional and half plan, or an inside and outside plan of the booms, in Figs. 7 and 11, together with elevations to a distorted scale of the number of plates and angle irons composing the upper and lower booms in Fig. 4. There are in each boom, not including the long extra plate doing duty as a cover plate or wrapper over all, seven horizontal flange plates, all 1ft. 6in. in width by ½in. in thickness, and varying in length from 29ft. 10in. to 10ft. 10in., riveted to the angle irons of the flanges by rivets ⅞in. in diameter, with a pitch of 4in. from centres. The flange angle irons, which are four in number, two to each separate section of the booms, are 4in. by 4in. by ½in.

In Fig. 3*a*, the diagonal struts are lettered S and the sloping ties T, and they both vary in dimensions, and consequently in sectional area, according to their position in the girder. For instance, the ties increase from 7in. by ⅝in. at or near the centre of the main girders to 1ft. 3in. by 1⅛in. at the ends. It will be observed that in the central bay, counting the whole number as thirteen, which includes the semi or incomplete bay over the east abutment, both the diagonal bars are ties, and each 7in. wide by ⅝in. thick, thus giving a gross sectional area of nearly exactly one-fourth of that of the diagonal ties in the end bays. In girders of the description under notice in which the dead load, that is the insistent, weight of the principal girders, and in fact of the whole superstructure together, may be regarded as uniformly distributed, and also when it bears a fairly high ratio to the rolling or live load, the stresses on the central diagonals of the web are comparatively small. When the girder is used solely to support a uniformly distributed dead or static load, there is theoretically no stress on the diagonals under notice, but it is as well even in an instance of this description not to adhere too closely to the abstract dictates of theory. As a case in point, we remember many years ago a young engineer, very zealous and energetic in matters pertaining to the designing and construction of girders, had some lattice girders built for carrying a large water tank, in which the central diagonal bars were absolutely left out. They were passed, it is true, after some difficulty, by the superintending engineer, but it was stipulated that for the sake of appearance, wooden bars were to be inserted, painted and fashioned so as closely to resemble their iron neighbours.

Apologising for our brief digression, we now return to the main girders of the bridge at Worship-street, and for further details refer our readers to Figs. 5—11. It will be seen from them that each main girder consists essentially of a pair of single open web girders, placed side by side and separated by a space equal to 1in., and as the boom of each girder is 1ft. 6in. broad, the distance between their centres is 1ft. 7in., and the total width from out to out 3ft. 1in. If, therefore, the girder had been in one piece—that is, if the booms had been continuous over their whole available width, a plate 3ft. in breadth would have been required. Unfortunately, the time by which the bridge had to be constructed did not permit of plates of this somewhat exceptional width being obtained, so that the engineer decided to build up the section in the manner described. In addition, therefore, to the plates and angle irons already specified, we have to add two vertical plates to each entire boom. These plates have, except over the bearings, a uniform depth of 1ft., but vary in thickness from ⅝in. at the centre to 1⅛in. in thickness at the ends of the girders, corresponding with respect to these dimensions with those similarly belonging to the respective diagonal tie bars, to which they are riveted by strong gusset pieces. Over the bearings these vertical plates have their depth increased to 1ft. 6in. The form and size of these latter vary with the width of the tie bars, and their thickness increases slightly towards the ends of the girders from ½in. to ⅝in. The ties, twelve in number, all pass outside the struts, and it will be observed from an inspection of Figs. 5 and 6, that neither the ties nor the struts extend down the sides of the vertical plates or between the angle irons of the flanges, but terminate flush, or nearly flush, with the free or uncovered edges of the vertical plate. On the other hand, the solid plate diaphragms extend in both the upper and lower booms to the angle irons of the flanges, as shown by the letters D in Figs. 5 and 3*a*, which represent them in front elevation, sectional plan, and in cross elevation in the plane of a transverse section of the main girder. The diaphragms which bridge over—that is, which are carried across the space of 1in. between the two separate parallel girders constituting the single main girder—are built of eight angle irons, each 3in. by 3in. by ½in., two plates 1ft. ½in. by ½in. riveted in between them, and covered at their joint in the centre of the space of 1in., already described, by a cover plate on each side of the joint, 8in. broad by ½in. in thickness. In order to make the diaphragms extend the whole distance between the angle irons of the flanges, the angle irons of the diaphragms are cranked so as to clear the vertical plates of the flanges.

In Figs. 8 and 9 are given an elevation and section of the struts comprised in the web of the main girders, which are all similarly built up, although varying in length and other dimensions. The section of struts 1 and 2 is made up of a pair of outside or flange plates 1ft. by 1⅛in., two tee irons 6in. by 4in. by ⅝in., cross braced in elevation by three tee irons 4in. by 2in. by ⅝in., or four diagonal flat bars 3in. wide by ⅝in. thick. These dimensions for the bracing are constant for all the struts, but in strut 3 the thickness of the outside plates is reduced to 1in., and that of the longitudinal tee irons to ½in. In strut 4 the corresponding scantlings are, outside plates 10in. by 1in., and tee irons 6in. by 3in. by ½in., which in struts 5 and 6 are reduced to 7in. by 1in. by ⅝in. respectively, and 6in. by 3in. by ⅝in. in both instances. The tee irons of all the struts are bent to allow the plates to pass in between the gusset pieces. Cast iron bed-plates—see Figs. 6 and 7—having a length of 5ft. 6in., a breadth of 4ft. 9in., and a thickness of 4in., are bolted to the abutments with two holding-down bolts, each 2¼in. in diameter, and form the bearings for the ends of the main girders. Temporary brackets, B in Figs. 3*a* and 5, were riveted to the ends of the main girders for the purpose of fixing them in position, but were subsequently removed when the bridge was completed. In Fig 10 is a transverse section on the square of the general disposition of the cross girders and the roadway and footpaths of the bridge. The cross girders, seen partly in elevation in Fig. 10, and partly in cross section in Fig. 12, are of the plate type, 40ft. 1in. in span, 3ft. 9in. deep at the centre, and composed of horizontal flange plates 1ft. 6in. by ½in., angle irons 3½in. by 3½in. by ½in., and a web plate ⅜in. thick at the centre, increasing towards the ends of the girders to ½in. At intervals of every 4ft. along the rib of the girder vertical stiffeners are riveted on both sides, consisting of plates 1ft. in breadth by ⅜in. in thickness, which are covered again by tee-irons measuring 6in. by 3in. by ⅜in. The spaces of 4ft. between the vertical stiffening plates and tee-irons decrease towards the ends of the girder to 3ft. 8in., 2ft. 8in., and 1ft. 4in. In all plate girders it is near the bearings where the rigidity of the web becomes of chief importance, and the necessity for vertical stiffeners the most urgent.

Considering the roadway for the moment as distinct from the footpaths, upon the cross girders are placed, every 4ft. apart, rolled steel joists 8in. deep by 5in. wide over each flange, and where their joints occur they are riveted together over the cross girders by a pair of cover plates 8in. by 6in. by ⅜in.—Fig. 12. Over the rolled steel joists are riveted to them, with rivets ⅝in. in diameter, wrought iron buckled plates 4ft. by 4ft. and ⅜in. thick, and with a rise or camber at the centre of 2½in.—Fig. 13. Transversely the rolled steel joists are connected together by tee-iron bearers 5in. by 3in. by ⅜in., shown by the letter T in Figs. 13 and 14, to which the other fillets of the buckled plates are riveted. A substratum of concrete overlaid by wooden sets—Figs. 10—completes the formation of the roadway, and the same figure shows the construction of the footpaths, which is as follows:—A strong rolled steel joist 12in. deep by 5in. in width, is carried by a wrought iron bracket or knee piece riveted to the stiffening tee-iron of the cross girder. To the upper flange of this joist are riveted the adjacent fillets of the two buckled plates supporting the materials of the footpaths, which consist of dry filling and concrete flushed over a layer of asphalte. In Figs. 3, 10, and 15, the side screens are shown, which, while doubtless an unavoidable item in the construction of the bridge, detract very much from its appearance. Fig. 15 is an elevation of one bay of the parapet or screen on the inside or roadway. Fig. 16 is a section of the cast iron moulding forming the upper edge of the parapet; and Fig. 17 is a section and elevation of the moulding around the edges of the panels in Fig. 15.

Although all the work in connection with the enlargement of the terminus was of a heavy and onerous character, yet at any rate, so far as bridges are concerned, that at Worship-street may be considered to have carried off the palm. In Fig. 1, is shown in dotted lines the original contours of the old bridge of two skew arches turned in brick, which previously spanned the tracks, with clear openings of 27ft. each on the square. Between parapets the width of the old bridge was 40ft., but if the depth of the warehouses on either side be added on, the total width amounted to 70ft. As it would have been impracticable to accommodate the number of new tracks fantailing into the enlarged terminus under the narrow area afforded by the two old skew arches, it was determined to demolish the structure altogether, including the central pier, which was of dimensions sufficient to absorb some twelve lineal feet in the cross section of the permanent way. The demolition or removal once accomplished, the restoration of the thoroughfare upon wrought iron girders spanning the entire width of line at this point would have, under ordinary circumstances, been unattended with any engineering difficulty especially worth recording. But the problem assumes a very different aspect when the work it embraced necessitated the execution of it without in any way interfering with the ordinary traffic of the railway below, and in a great measure with that above. To carry on to a successful termination the destruction of the old and the erection of the new bridge in a single span, when about eight hundred trains every twenty-four hours had to be allowed an uninterrupted passage during the operation, was the feat to be accomplished by the Great Eastern Railway and its contractors.

For the information respecting this stage of the work we are indebted to Mr. H. L. Batting, of the firm of The Horseley Company, Limited, of Tipton, Staffordshire, and Victoria-street, Westminster, who were the contractors for the construction and erection of all the ironwork, not only for the present bridge, but also for the adjacent similar structures at Primrose and Skinner streets. In commencing the work of destruction, the warehouses already referred to were first demolished, and a temporary bridge of timber was built to carry the water and gas mains which supplied the districts on the north-east side of the extension with those requisites demanded by modern civilisation. In addition to serving the purpose described, the temporary structure acted as a bridge for pedestrians until the original thoroughfare was completely re-opened for traffic; for it was never entirely closed during the whole of the work, except for a very brief interval of time, which will be subsequently alluded to. It should be mentioned here, before proceeding further with our description, that no less than three separate authorities or parties were concerned, and took an active part in the execution of the works in connection with the removal and re-erection of Worship-street bridge. They were the Great Eastern Railway, the Horseley Company, and the contractors for the earthwork, brickwork, and foundations, Messrs. Mowlem and Co., who carried out, with the exception of the ironwork, the building of the new parcels' office already described and illustrated in THE ENGINEER. Having cleared away the warehouses, the contractors were at liberty to utilise the space thus acquired for

"THE ENGINEER." SWAIN ENG.

the erection of the two main girders, of the largest of which we have given general and detail drawings in the present article. While so doing, the roadway had to be kept clear for the passage of the ordinary traffic. To those acquainted with the locality, the necessity for regulations so stringent with respect to the non-interruption with the ordinary road traffic, is not quite apparent. A small detour, with a correspondingly small sacrifice of time, would cause but a very insignificant interference with the main arterial routes, although, it must be admitted, the vehicular traffic in and about Bishopsgate, Norton Folgate, and Shoreditch is of both a frequent and heavy description. No sooner had the main girders been built *in situ*, than it became necessary to cut away the arches and all the brickwork underneath. This duty devolved upon the railway company and the resident engineer, Mr. Sherlock, and the district engineer, Mr. Wilmer, under the engineer-in-chief, Mr. Wilson, who had the charge of the work.

In order to protect the incoming and outgoing trains from the fall of the old materials, which were now nothing more than so much useless *débris*, old rails, iron odds and ends, balks and half balks of timber of a handy length, and scantlings and timber lagging, were pressed into the service, and a strong and substantial screen shield or platform was speedily interposed between the demolition above and the steam locomotion beneath. The steel wedge, the hammer and the pick were now brought into requisition, the side portions of the arches cut away, and the new main girders lowered down upon their bedstones. Under the powers of its Act of Parliament the company were able to stop the entire traffic of the roadway for a period not exceeding 168 hours. This brief interval was thus allotted among the different parties engaged in the work:—Messrs. Mowlem and Co., to remove all pitching, old material, and cart away earth, 24 hours; the Great Eastern Railway, to cut away completely all the brickwork of the arches and remove the shield, 96 hours; the Horseley Company, to fix all the cross girders and platform, 48 hours; total, 168 hours.

A few words must be said respecting the manner in which the cross girders were got into place. When the main girders were fixed in position, a rough sort of a travelling gantry was rigged up over the roadway, and running along the upper booms at a slow pace. A special goods train hauled the cross girders, weighing some five tons each, underneath the new bridge, and from the trucks they were lifted bodily by the gantry to their permanent position on the main girders, to which they were ultimately riveted in the manner already described. In addition to the ironwork required for the three new bridges over the terminal enlargement, supplied by the Horseley Company, Messrs. John Mowlem and Co. used a large quantity in carrying out their contract with the Great Eastern Company for widening the thoroughfares from Bishopsgate-street Without to Globe-road, and from Bethnal Green to Hackney Downs.

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this Society was held on Wednesday evening, the 15th inst., at the Institution of Civil Engineers, Westminster; Mr. E. Mawby, president, in the chair. Mr. W. Ellis, F.R.S, read a paper on the "Mean Amount of Cloud on Each Day of the Year at the Royal Observatory, Greenwich, on the average of the Fifty Years, 1841-90," in which he showed that a principal maximum occurs in winter and a principal minimum in autumn, with a secondary much less pronounced maximum in summer and a secondary minimum in spring. There is, however, considerable irregularity in the succession of daily values, the differences between which on consecutive days are, in numerous cases, relatively large. Cloudless days are most numerous in spring and autumn, and least so in winter and summer; days of little cloud are somewhat less numerous in winter as compared with other parts of the year, whilst days of medium cloud are much more numerous in summer than in winter. Days of much cloud are nearly equal in amount in all parts of the year, whilst overcast days are much more numerous and nearly equal in amount in the first and fourth quarters of the year, much less numerous in the second quarter, and again less numerous in the third quarter. Mr. E. D. Fridlander, B.Sc., gave an account of "Some Observations of the amount of Dust in the Atmosphere, made at Various Places during a Voyage Round the World in 1894-5." The experiments, which were made with a form of Aitken's pocket dust counter, showed that there are often considerable variations in the number of dust particles in a very short space of time. Not only did dust occur in the air of inhabited countries, over the water surfaces immediately adjoining them, and up to an altitude of 6000ft. or 7000ft. amongst the Alps, but it was also found in the open ocean, and that so far away from any land as to preclude the possibility of artificial pollution, and its existence has been directly demonstrated at a height of more than 13,000ft. Major H. E. Rawson, F.R. Met. Soc., gave an "Analysis of the Greenwich Rainfall Records from 1879 to 1890, with Special Reference to the Declination of the Sun and Moon."

BIRMINGHAM ASSOCIATION OF MECHANICAL ENGINEERS.—A paper was read before this Association at its last meeting by the first president of the society, Mr. Thomas Meacock, on "The Application of Electricity to Motive Power Purposes." The author treated the subject under the following four divisions:—(1) The application of electricity to tramcar propulsion; (2) to factory driving; (3) to domestic uses; (4) general application. Upon the topic of tramcar propulsion, the author defined the position of the three parties interested in tramways, viz., the tramway companies, the corporate Councils, and the public. The former having the paramount question of first cost or capital outlay to consider, turned to the overhead trolley electric system for the equipment or re-equipment of their lines, as the only system at present available which can be laid at comparatively moderate cost. The corporate councils finding the electric conduit system too costly, finally sanctioned the overhead trolley scheme. The public invariably petitioned against the overhead trolley scheme, but up to the present time had not been able to find a substitute, first cost being the barrier to other systems for ordinary services. The author then described a system devised by his own firm which removed the barrier of excessive first cost, gave no obstruction above the street level, and was perfectly insulated. He trusted that shortly the scheme would be put to practical use. Treating the question of factory-driving, the author whilst admitting that the application of an electric motor to each individual machine was the ideal system, still in practice he suggested a judicious grouping of the machines, with light line shaft and electric motor to each group, as the most practical scheme as regards first cost, maintenance, and efficiency. After going somewhat fully into the question of electricity as a motive power, he described a regulating slipping device he had designed for relieving the motor of all shocks from the machinery. Upon the third topic—the application of electricity to domestic purposes—he maintained that the time had now arrived when the great boon of electricity, now only available in towns, leading hotels, and public institutions, should be within reach of residents in suburban and rural districts. Mr. Meacock proposed a scheme of what he termed electrical colonisation, or grouping of, say, a dozen residences, having a common generating station, with attendant, which would supply the electricity for the group of residences.

EXPERIMENTS WITH ACCUMULATORS FOR LIGHTING RAILWAY CARRIAGES.*

DURING the past year a series of exhaustive experiments was carried out by the officials of the Hungarian State Railways on the lighting of railway carriages by electricity, and several systems of accumulators were made the subject of examination.

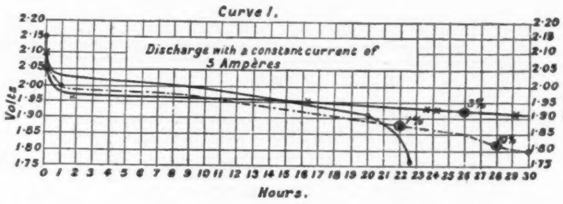
The conditions operating when vehicles in motion are to be illuminated differ appreciably from those obtaining in the case of stationary installations. In the latter event the weight of the accumulators is practically of little moment, and the diminution of the tension of the current as the discharge progresses can be easily compensated by the addition of reserve cells. This must, however, be avoided in railway work, as entailing too great a degree of complexity in the apparatus and inconvenience in application, and the following essentials, viz., lightness, regularity of current, and high capacity, are therefore insisted upon by the railway authorities.

Some makers endeavour to conform to the first-named condition by employing comparatively light plates containing very little metallic lead, but a great proportion of more active "paste." To this category belong the Austria and Boese accumulators. On the other hand, the Accumulator Manufacturing Company at the Hague adhere for railway work to a modification of their Tudor battery, wherein the plates have a very large surface, their capacity being increased by the superimposition of suitable "paste," with the object of reducing to a minimum the decrease of current while discharging. The importance of this latter condition is considerable, a diminution of 5 per cent. from the initial strength of the current being sufficient to lower the candle-power of the lamps to such a degree as to reduce the battery below the limit of practical efficiency.

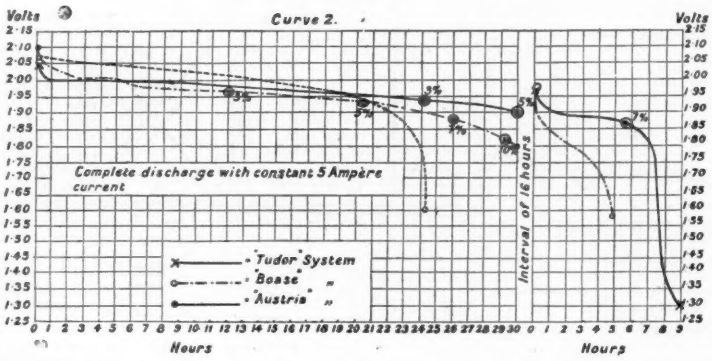
These two competitive systems being at disposal, a comparative examination of their respective merits fell within the scope of the experiments alluded to above, the batteries subjected to the different practical tests and measurements being of the Tudor, Boese, Austria, and Bristol types.

After having been in constant use for a period of over six months the batteries were all discharged and recharged, until gas was freely evolved. The discharging was then proceeded with at the strength of current, and until the final tension detailed in the subjoined tables, which, together with the curves, show the results obtained.

Curve 1.



Curve 2.



First Discharge.

System.	Strength of discharge current in ampères.	Final tension in volts per cell.	Guaranteed capacity in ampère-hours.	Actual capacity in ampère-hours.	Percentage diminution in tension.	Percentage of guaranteed capacity.	Density of the electrolyte at completion of discharge.
Tudor ..	5	1·85	150	150	3·3	100	16° and 15° Bé
Boese ..	5	1·80	150	150	10·0	100	14½° Bé
Austria ..	5	1·80	180	112	11·8	62	16½° and 16° Be
Bristöl ..	4	1·80	87·5	8·5	7·3	23	could not be measured

The accumulators were then fully charged once more and finally discharged completely—see second table and curve.

Second Discharge.

System.	Strength of discharge current in ampères.	Final tension in volts per cell.	Guaranteed capacity in ampère-hours.	Actual capacity in ampère-hours.	Percentage diminution in tension.	Percentage of guaranteed capacity.	Density of the electrolyte at completion of discharge.
Tudor ..	5	1·85	150	184	7·5	123	13° Bé
Boese ..	5	1·80	150	161	11·8	108	—
Austria ..	5	1·80	180	119	12·8	66	—
Bristöl ..	Not	tested	any fur	ther.			

After proceeding with the discharge for thirty hours, a rest of fifteen hours was allowed, and then discharging was resumed until complete. Finally a cell was selected from each of the batteries that had been in use for six months, and was taken to pieces to allow its eternal condition to be examined. The Tudor and Boese alone passed this test satisfactorily.

The tables below show the actual capacity—as obtained from the analysis of the curves—of the Tudor and Boese accumulators, at reductions of voltage amounting to 3, 5, and 7 per cent. respectively.

Initial tension per element in volts	Boese 2·000 Tudor 1·985	3 per cent.	5 per cent.	7 per cent
Final ditto	Boese	1·940 ..	1·900 ..	1·860
	Tudor	1·925 ..	1·886 ..	1·846
Actual capacity in ampère-hours.				
Boese		72·5 ..	107·5 ..	132·5
Tudor		146·3 ..	above 150·0 ..	above 157·0

Initial tension per element in volts	Boese 2·040 Tudor 2·000	3 per cent.	5 per cent.	7 per cent.
Final ditto	Boese	1·9788 ..	1·938 ..	1·8972
	Tudor	1·9400 ..	1·900 ..	1·8600
Actual capacity in ampère-hours.				
Boese		52·5	.. 100·0	127·5
Tudor		131·3	.. 167·5	181·3

Mean value of the foregoing measurements:—

	At 3 per cent. Ampère-hours.	At 5 per cent. Ampère-hours.	At 7 per cent. Ampère-hours.
Boese	62·50	103·75	130·00
Tudor	138·80 ..	about 167·50	181·30

The Tudor accumulator thus possesses an appreciably higher absolute capacity than the Boese battery. The weights of the accumulators used were:—

Tudor	12 elements in	6 troughs of	2·44 kilos.	per trough	=264 kilos.*	
Tudor	12 ,,	,, 6 ,,	,, 2·36½	,, ,, ,,	= 219 ,,	†
Boese	12 ,,	,, 6 ,,	,, 2·28	,, ,, ,,	= 168 ,,	
Austria	12 ,,	,, 2 ,,	,, 6·64	,, ,, ,,	= 128 ,,	
Bristol	48 ,,	,, 8 ,,	,, 6·27¾	,, ,, ,,	= 222 ,,	

Under equal conditions of reduction of tension the weight per ampère-hour of capacity is thus:—

	At 3 per cent. Kilos.	At 5 per cent. Kilos.	At 7 per cent. Kilos.
Boese	2·688	.. 1·619	1·290
Tudor	1·578	about 1·307	1·208

Therefore within the permissible limit of reduction, viz: 5 per cent., the Tudor accumulator is, notwithstanding its greater absolute weight, lighter in proportion to its effective capacity than the Boese battery, and it is only when the reduction of voltage amounts to 7 per cent. that the relative weights coincide.

LAUNCH OF A TORPEDO GUN VESSEL FOR CHILI.

THE Birkenhead Ironworks are at present very actively employed in the construction of war vessels of various types for our own naval service and for several friendly Powers, for whose navies as well as our own the acquisition of the most modern type of fighting ship of the very highest speed is of paramount importance, as is evidenced by the fact that the great majority of vessels now building at those works are designed for a speed of 30 knots, while there is nothing at present on the stocks of a less speed than 21 knots. A fortnight ago Messrs. Laird floated out of one of their building docks, H.M.S. Mars, of 14,900 tons and 12,000 indicated horse-power, which is now under the 90-ton crane in the west float, receiving the remainder of her machinery.

Last week they launched a very fast and formidable torpedo gunboat for the Chilian Government, very similar in design and dimensions to the Almirante Lynch and Almirante Condell, built by the same firm for the Chilian Government in 1890. The new vessel was named the Almirante Simpson, and was christened by Madame Goni, wife of Captain Luis A. Goni, of the Chilian Navy, late head of the Chilian Naval Commission in Europe. Her length over all is 240ft. with a beam of 27ft. 6in., and a depth of 16ft., and she measures 858 tons, o.m. She is, of course, constructed of steel. She has a forecastle and a half poop which provide good accommodation for officers and crew, there is a fore-and-aft bridge at the height of forecastle deck connecting with the poop, and to this level the casings of hatchways and engine-room skylights are carried, the openings on main deck level being water-tight. The hull is sub-divided into numerous water-tight compartments by transverse bulkheads, and longitudinal bulkheads divide the two sets of engines, and extend along the outer sides of the machinery spaces, so that great power of flotation is insured in case of injury. The side and deck plating abreast the machinery spaces are of increased thickness to afford protection, and the coal bunkers are also arranged with this object, and of large capacity. The armament, of the most recent type, will consist of one bow and two broadside torpedo tubes, two 4·7in. guns, four 3-pounder quick-firing guns, and two machine guns and mining plant. The machinery will consist of two sets of Messrs. Laird's high-speed triple-expansion engines, developing about 5000 indicated horse-power collectively, driving twin screws, and designed to give the vessel a speed of 21 knots. The boilers are four in number, of the Normand tubulous type, with a working pressure of 200 lb. per square inch. Range of action at 10 or 11 knots speed, about 4000 knots.

Among those present were Admiral Uribe, chief of the Chilian Naval Commission; Sir E. J. Reed, K.C.B., consulting naval architect; Captain Luis A. Goni, of the Chilian Naval Commission; Captain Romulo Medina, C.N.; Mr. J. Forbes, inspecting engineer; Mr. Bernal, engineer; Mr. C. B. Nichols, Mr. T. H. Wells; Mr. Cockbain, Chilian Consulate, Liverpool; Mr. Moller, Chilian Consul, Manchester, and Mrs. Moller; Mr. Meyer, German Vice-consul; Mons. Sève, Belgian Consul-General, &c.

TRADE AND BUSINESS ANNOUNCEMENT.—The Harrison Engine Company, Limited, has taken over the business of the Harrison Patent Steering Engine Company, Limited, and appointed Mr. R. W. White managing director—for many years with Messrs. Hulse and Co., Manchester.

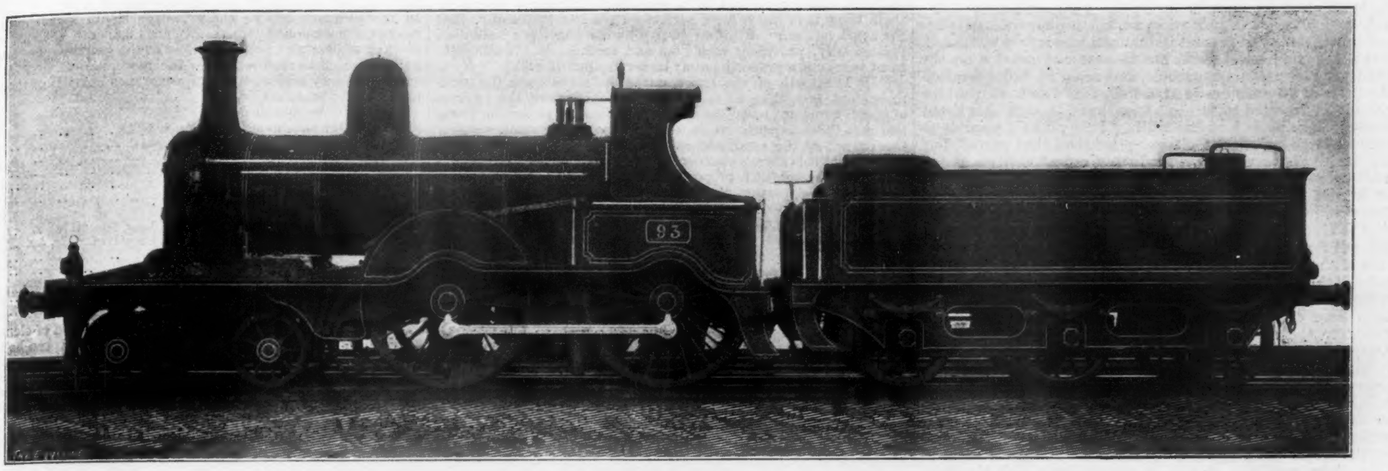
---

* G. Klose, "Zeitschrift des Oesterreichischen Ingenieur-ünd Architekten Vereines," xlviii. No. 7.

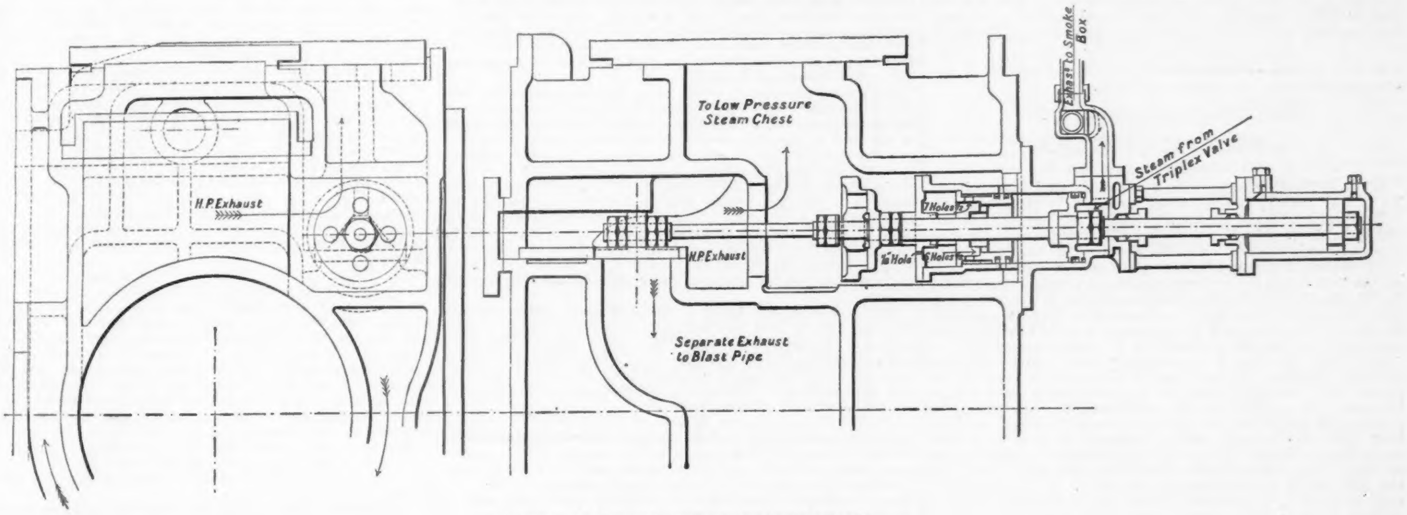
* First pattern. † Second pattern.

COMPOUND EXPRESS ENGINE, GREAT SOUTHERN AND WESTERN RAILWAY.

ABOUT five years ago the Great Southern and Western Railway Company converted one of its standard goods engines into a compound on the Worsdell and Von Borries plan. A pair of cylinders 18in. and 26in. diameter by 24in. stroke was substituted for the two 18in. cylinders. The compound cylinders were adapted to the existing standard crank centres, and with the 5ft. 3in. gauge, this left space for the low-pressure valve to be placed between the cylinders, in which position it is driven direct, the high-pressure valve is placed on the top of its cylinder and is driven with a rocking shaft. This arrangement enabled the standard motion to be retained, so that practically the engine could be altered to simple again at any time by changing the cylinders.



COMPOUND EXPRESS ENGINE, GREAT SOUTHERN AND WESTERN RAILWAY, IRELAND



IVATT'S COMPOUND ENGINE CHANGE VALVE

The pressure was purposely kept the same as in the standard goods engines, viz., 150 lb., in order to see whether the engine showed any economy due to the compounding alone. The result has been that the engine, which has now been at work for five years, shows a saving in coal consumed of about 10 per cent. as compared with other engines doing the same work. The cost for repairs, and lubrication, &c., has not been greater than in the case of other engines of the company's standard goods type.

Mr. Ivatt considered the results obtained with the goods-engine after an extended trial, sufficiently encouraging to warrant him in recommending his directors to sanction the construction of a compound express engine, of which we give on page 424 an elevation, and in a future impression we shall publish sectional drawings.

The chief dimensions are as follows:—Cylinders 18in. and 26in. by 24in. stroke. Wheels, 6ft. 7½in., four coupled. Heating surface: fire-box, 112 square feet; tubes, 824 square feet; total, 936 square feet; grate area, 18¾ square feet; steam pressure, 150 lb. Weight of engine in working order, 40 tons, distributed as follows: on bogie, 15 tons; driving, 13 tons; trailing, 12 tons. These weights are light compared with those common on many English lines, but the engine is designed for running on a 74 lb. rail. The engine is built under the Worsdell, von Borries and Lapage's patents, with an arrangement of change valve designed by Mr. Ivatt. This valve, of which we give a section, allows the engine to be worked "simple" or "compound" at will. It is actuated by a small lever and rod from the foot-plate, which, by suitable valves admits steam to a cylinder on the spindle of the change valve, and so moves it to either position, the movement being controlled by a dashpot. When in the "simple" position the valve opens a communication from the high-pressure exhaust to the blast pipe, round the underside of the high-pressure cylinder; at the same time it closes the communication from the high-pressure exhaust to the low-pressure steam chest, and opens a connection for live steam from the steam pipe to the low-pressure steam chest. This supply of live steam is wiredrawn so as not to exceed about 75 lb. pressure on the low-pressure side, and the low-pressure cylinder and steam chest are, as usual, provided with relief valves, set to blow at 75 lb. in case the pressure should exceed that amount.

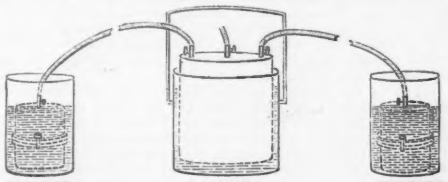
In ordinary working the engine is always run compound, and starts without any trouble, but for starting on an incline, or for getting away quickly with a heavy train, the arrangement for working simple is of great advantage, and enables the engine to exert as much power as a simple engine with two 18in. cylinders and the same steam pressure. The arrangement is also exceedingly handy for shunting; there is no steam locked up in the receiver, and the engine does not, in steam-shed phraseology, "beat two or three times after steam is shut off."

The working of the change valve is entirely in the hands of the driver. Mr. Ivatt does not believe in the theory that it is not advisable to give the driver the power of working simple if required. To argue that the driver of a compound engine so fitted is likely to work the engine simple any longer than is absolutely necessary, is about the same as saying that the driver of an ordinary engine cannot be trusted to pull the reversing gear up as soon as possible.

The engine has only been at work about eight months, consequently no accurate information as to comparative consumption of coal, &c., is yet available. She is doing the same work as other express engines with similar boiler and pressure, but with cylinders 18in. by 24in., four coupled, with same size of wheel.

COMMERCIAL VALUE OF ACETYLENE.

THE first practical demonstration, says a French correspondent, of the illuminating qualities of acetylene gas produced by the contact of calcium carbide with water was made at the meeting of the French Société du Gaz in June of last year. It was then generally admitted that the new gas was destined to revolutionise the existing systems of lighting, but few people could have anticipated that it would have made so much progress as a commercial product in the short time that has elapsed since then. The experiments carried out at the meeting were necessarily imperfect, and the amount of smoke given off by the flame had, of course, to be suppressed before the gas could be used for lighting purposes. This has been done simply by the employment of a special burner in which the orifice is smaller than in the ordinary gas burner. This economy is indeed one of the features of acetylene, for with one kilo. of calcium carbide and 500 grammes of water the amount of gas produced is 300 litres, and this, it is stated, will provide a light equal to fifteen ordinary gas jets for six hours, while, if a smaller burner is used, the duration is, of course, much greater. To give a comparison between the cost of ordinary gas and acetylene in France, where the latter is now being produced upon something like a commercial scale, it may be said that the price of coal gas per carcel hour is one centime, while acetylene gas costs 3·2 centimes, but as acetylene is so much more powerful, the two gases work out in practice to about the same figure. While admitting these enormous advantages, the question was raised in the early stages of development whether acetylene was not more poisonous than ordinary gas, but experiments have shown, it is said, that there must be at least 40 per cent. in the atmosphere before it can be dangerous, and its presence can be distinguished long before it attains to this proportion. In burning it has no perceptible odour whatever.



Another advantage claimed for acetylene, so far as lighting is concerned, is that it gives off very little heat, and this naturally tells against its employment for the many domestic purposes to which ordinary gas is applied upon such a large scale in France. Nor can it be compared with coal gas for the driving of motors, though it is believed that when acetylene comes to be generally adopted it will be used for cooking, heating, and power purposes simply by consuming the new gas in larger quantities than ordinary gas to give the same caloric result. But, for the moment, the only scope that is opened to acetylene is for lighting. The chances of explosion are held to be not greater than with ordinary gas, and it may even be deemed safer on account of the fact that it is produced upon a much smaller scale. This facility of manufacture is one of the arguments urged for acetylene. By the aid of small appliances the gas may be produced in any household, and may be manufactured as required on steamboats and trains. A great many such appliances have already been constructed, in which the chief objects aimed at are that they should occupy very little space, that they may be placed in the care of any servant or labourer without fear of accident, and that they should be very cheap. Until lately the appliances, such as those manufactured by MM. Escher Wyss and Co., of Zurich, have run into very high figures, but now acetylene producers, claimed to be of equal quality, are sold for about a sixth of the amount, while the cheapest on the market, having a capacity of 1 kilo. of calcium carbide, and providing a light equal to ten ordinary burners for six hours, is priced at £6. These appliances are now being supplied by a company which has just been formed in Paris under the title of Le Gaz Acétylene.

The company is placing on the market an apparatus known as an "At Home," and composed of a gas-holder and one or two producers, according to whether the supply is to be continuous or not. The producer contains a closed cylinder, into which an iron wire receptacle holding the calcium carbide is introduced. The two parts of the cylinder are brought together by catches which make it water-tight. The cylinder is then just covered with water which finds its way inside by means of a small pipe. The gas-holder is constructed upon the ordinary principle, and the pressure is so adjusted that when the bell rises the water cannot enter into the calcium carbide receptacle. Upon its descending, however, the water enters the producer in just the quantity necessary to again fill the gas-holder, and so on until the whole of the carbide is decomposed. When a constant supply is needed the installation comprises two producers, so that on one becoming exhausted the tap connecting it with the gasometer is closed, and the other producer is put into communication. The Company Le Gaz Acétylène possesses several other patents, notably the Boesmann apparatus, and another. The former will supply gas for from 200 to 1500 burners. A very simple form of home acetylene gas make was recently illustrated in the *Scientific American*. The company has also been experimenting with liquid acetylene under pressure, varying from 25 to 50 atmospheres, but in consequence of this great pressure it has not been thought advisable to use the liquid, the more so as the gas is produced in the apparatus described under a pressure of not more than 20 centimetres of water. Now that the necessary appliances for producing acetylene are on the market, or will be in a short time when Le Gaz Acétylène will be manufacturing ten producers a week, the only difficulty lies in procuring sufficient quantities of pure calcium carbide. At present its manufacture is very restricted, but a large number of works are in course of erection on the Continent for producing carbide, and when in full operation the price of 70 centimes to 1f. a kilo. that has to be paid for carbide is expected to fall to 50 centimes, though this is not likely to take place for some while. It is yet still possible to procure large supplies at a lower price than that quoted, but the quality is very inferior, producing only 150 litres of gas a kilo. instead of 300 litres. A good deal has been said of late as to the large quantities capable of being produced in America, but so far not a single kilo., it is said, has found its way to Europe. On this side, it would probably be extremely difficult for the moment to secure supplies of ten tons a day. One of the problems which Le Gaz Acétylène has set itself to solve is the finding of a portable lamp, but there are a great many difficulties in the way of this being done. Such lamps have been constructed, but they are entirely impracticable owing to their liability to explode. As to the future of acetylene, there can be little doubt but that in course of time it may be employed for lighting purposes upon a very considerable scale. For the moment, it cannot come into competition with ordinary gas for town lighting in Paris, owing to the fact that not only is the latter more suitable for cooking and heating, but the monopoly of lighting is enjoyed by the Paris Compagnie du Gaz, and no change is likely to take place until the monopoly expires, by which time the price of calcium carbide may be so cheap that the new concessionaires may see it to their advantage to employ the new gas, the more so as no great change in the present system of piping is necessary. In laying down new installations for acetylene smaller pipes need only be used, with a consequent economy in cost, while the manufacturing plant is, of course, infinitely more simple and less costly. The aim of Le Gaz Acétylène is, therefore, to supply the new gas in places where there is no ordinary gas or electricity, and the directors think that it is especially adapted to luminous advertising, and to other purposes where the ordinary gas does not give a sufficiently brilliant light. It is significant of the interest that is being taken in acetylene that though the company has only been recently formed it is yet receiving innumerable demands for information from all parts of the world, and, according to our correspondent, there is a prospect of the new gas taking up a prominent position.

A PIECE-RATE SYSTEM.*

(*Continued from page* 392.)

(28) A still further improvement of this method was made by Mr. F. A. Halsey, and described by him in a paper entitled, "The Premium Plan of Paying for Labour," and presented to this society in 1891. Mr. Halsey's plan allows free scope for each man's personal ambition, which Mr. Towne's does not.

(29) Messrs. Towne and Halsey's plans consist briefly in recording the cost of each job as a starting-point at a certain time; then, if, through the effort of the workmen in the future, the job is done in a shorter time and at a lower cost, the gain is divided among the workmen and the employer in a definite ratio, the workmen receiving, say, one-half, and the employer one-half.

(30) Under this plan, if the employer lives up to his promise, and the workman has confidence in his integrity, there is the proper basis for co-operation to secure sooner or later a large increase in the output of the establishment. Yet there still remains the temptation for the workman to "soldier" or hold back while on day-work, which is the most difficult thing to overcome. And in this, as well as in all the systems heretofore referred to, there is the common defect, that the starting point from which the first rate is fixed is unequal and unjust. Some of the rates may have resulted from records obtained when a good man was working close to his maximum speed, while others are based on the performance of a medium man at one-third or one-quarter speed. From this follows a great inequality and injustice in the reward even of the same man when at work on different jobs. The result is far from a realisation of the ideal condition in which the same return is uniformly received for a given expenditure of brains and energy. Other defects in the gain-sharing plan, and which are corrected by the differential rate system, are:—(*a*) That it is slow and irregular in its operation in reducing costs, being dependent upon the whims of the men working under it; (*b*) that it fails to especially attract first-class men and discourage inferior men; (*c*) that it does not automatically ensure the maximum output of the establishment per man and machine.

(31) Co-operation, or profit-sharing, has entered the mind of every student of the subject, as one of the possible and most attractive solutions of the problem; and there have been certain instances, both in England and France, of at least a partial success of co-operative experiments. So far as I know, however, these trials have been made either in small towns, remote from the manufacturing centres, or in industries which in many respects are not subject to ordinary manufacturing conditions.

(32) Co-operative experiments have failed, and, I think, are generally destined to fail, for several reasons; the first and most important of which is, that no form of co-operation has yet been devised in which each individual is allowed free scope for his personal ambition. This always has been and will remain a more powerful incentive to exertion than a desire for the general welfare. The few misplaced drones, who do the loafing and share equally in the profits with the rest, under co-operation are sure to drag the better men down towards their level.

(33) The second and almost equally strong reason for failure lies in the remoteness of the reward. The average workman—I don't say all men—cannot look forward to a profit which is six months or a year away. The nice time which they are sure to have to-day, if they take things easily, proves more attractive than hard work, with a possible reward to be shared with others six months later.

(34) Other and formidable difficulties in the path of co-operation are the equitable division of the profits, and the fact that, while workmen are always ready to share the profits, they are neither able nor willing to share the losses. Further than this, in many cases it is neither right nor just that they should share either in the profits or the losses, since these may be due in great part to causes entirely beyond their influence or control, and to which they do not contribute.

(35) When we recognise the real antagonism that exists between the interests of the men and their employers, under all of the systems of piece-work in common use; and when we remember the apparently irreconcilable conflict implied in the fundamental and perfectly ligitimate aims of the two—namely, on the part of the men: *The universal desire to receive the largest possible wages for their time;* and on the part of the employers: *The desire to receive the largest possible return for the wages paid;* what wonder that most of us arrive at the conclusion that no system of piece-work can be devised which shall enable the two to co-operate without antagonism, and to their mutual benefit!

(36) Yet it is the opinion of the writer that even if a system has not already been found which harmonises the interests of the two, still the basis for harmonious co-operation lies in the two following facts:—First, that the workmen in nearly* every trade can and will materially increase their present output per day, provided they are assured of a permanent and larger return for their time than they have heretofore received; secondly, that the employers can well afford to pay higher wages per piece even permanently, providing each man and machine in the establishment turns out a proportionately larger amount of work.

(37) The truth of the latter statement arises from the well-recognised fact that, in most lines of manufacture, the indirect expenses equal or exceed the wages paid directly to the workmen, and that these expenses remain approximately constant, whether the output of the establishment is great or small. From this it follows that it is always cheaper to pay higher wages to the workmen when the output is proportionately increased; the diminution in the indirect portion of the cost per piece being greater than the increase in wages. Many manufacturers, in considering the cost of production, fail to realise the effect that the *volume of output has on the cost.* They lose sight of the fact that taxes, insurance, depreciation, rent, interest, salaries, office expenses, miscellaneous labour, sales expenses, and frequently the cost of power—which in the aggregate amount to as much as wages paid to workmen—remain about the same whether the output of the establishment is great or small.

(38) In our endeavour to solve the piece-work problem by the application of the two fundamental facts above referred to, let us consider the obstacles in the path of harmonious co-operation, and suggest a method for their removal.

(39) The most formidable obstacle is the lack of knowledge on the part of both the men and the management—but chiefly the latter—of the quickest time in which each piece of work can be done; or, briefly, the lack of accurate time-tables for the work of the place.

(40) The remedy for this trouble lies in the establishment in every factory of a proper rate-fixing department; a department which shall have equal dignity and command equal respect with the engineering and managing departments, and which shall be organised and conducted in an equally scientific and practical manner.

(41) The rate-fixing as at present conducted, even in our best managed establishments, is very similar to the mechanical engineering of fifty or sixty years ago. Mechanical engineering at that time consisted in imitating machines which were in more or less successful use, or in guessing at the dimensions and strength of the parts of a new machine; and as the parts broke down or gave out, in replacing them with stronger ones. Thus each new machine presented a problem almost independent of former designs, and one which could only be solved by months or years of practical experience and a series of break-downs. Modern engineering, however, has become a study, not of individual machines, but of the resistance of materials, the fundamental principles of mechanics, and of the elements of design.

(42) On the other hand, the ordinary rate-fixing—even the best of it—like the old-style engineering, is done by a foreman or superintendent, who, with the aid of a clerk, looks over the record of the time in which a whole job was done as nearly like the new one as can be found, and then guesses at the time required to do the new job. No attempt is made to analyse and time each of the classes of work, or elements of which a job is composed; although it is a far simpler task to resolve each job into its elements, to make a careful study of the quickest time in which each of the elementary operations can be done, and then to properly classify, tabulate, and index this information, and use it when required for rate-fixing, than it is to fix rates with even an approximation to justice, under the common system of guessing.

(43) In fact, it has never occurred to most superintendents that the work of their establishments consists of various combinations of elementary operations which can be timed in this way; and a suggestion that this is a practical way of dealing with the piece-work problem usually meets with derision, or, at the best, with the answer that "It might do for some simple business, but my work is entirely too complicated."

(44) Yet this elementary system of fixing rates has been in successful operation for the past ten years, on work complicated in its nature, and covering almost as wide a range of variety as any manufacturing that the writer knows of. In 1883, while foreman of the machine shop of the Midvale Steel Company, of Philadelphia, it occurred to the writer that it was simpler to time each of the elements of the various kinds of work done in the place, and then find the quickest time in which each job could be done, by summing up the total times of its component parts, than it was to search through the records of former jobs, and guess at the proper price. After practising this method of rate-fixing himself for about a year, as well as circumstances would permit, it became evident that the system was a success. The writer then established the rate-fixing department, which has given out piece-work prices in the place ever since.

(45) This department far more than paid for itself from the very start; but it was several years before the full benefits of the system were felt, owing to the fact that the best methods of making and recording time observations of work done by the men, as well as of determining the maximum capacity of each of the machines in the place, and of making working tables and time tables, were not at first adopted.

(46) Before the best results were finally attained in the case of work done by metal-cutting tools, such as lathes, planers, boring mills, &c., a long and expensive series of experiments was made, to determine, formulate, and finally practically apply to each machine the law governing the proper cutting speed of tools; namely, the effect on the cutting speed of altering any one of the following variables; the shape of the tool—*i.e.*, lip angle, clearance angle, and the line of the cutting edge—the duration of the cut, the quality or hardness of the metal being cut, the depth of the cut, and the thickness of the feed or shaving.

(47) It is the writer's opinion that a more complicated and difficult piece of rate-fixing could not be found than that of determining the proper price for doing all kinds of machine work on miscellaneous steel and iron castings and forgings, which vary in their chemical composition from the softest iron to the hardest tool steel. Yet this problem was solved through the rate-fixing department and the "differential rate," with the final result of completely harmonising the men and the management, in place of the constant war that existed under the old system. At the same time the quality of the work was improved, and the output of the machinery and the men was doubled, and in many cases trebled. At the start there was naturally great opposition to the rate-fixing department, particularly to the man who was taking time observations of the various elements of the work; but when the men found that rates were fixed without regard to the records of the quickest time in which they had actually done each job, and that the knowledge of the department was more accurate than their own, the motive for hanging back or "soldiering" on this work ceased, and with it the greatest cause for antagonism and war between the men and the management.

(48) As an illustration of the great variety of work to which elementary rate-fixing has already been successfully applied, the writer would state that, while acting as general manager of two large sulphate pulp mills, he directed the application of piece-work to all of the complicated operations of manufacturing throughout one of these mills, by means of elementary rate-fixing, with the result, within eighteen months, of more than doubling the output of the mill. The difference between elementary rate-fixing and the ordinary plan can perhaps be best explained by a simple illustration. Suppose the work to be planing a surface on a piece of cast iron. In the ordinary system the rate-fixer would look through his records of work done by the planing machine, until he found a piece of work as nearly as possible similar to the proposed job, and then guess at the time required to do the new piece of work. Under the elementary system, however, some such analysis as the following would be made:—

Work done by man.	Minutes.
Time to lift piece from floor to planer table	—
Time to level and set work true on table	—
Time to put on stops and bolts	—
Time to remove stops and bolts	—
Time to remove piece to floor	—
Time to clean machine	—
Work done by machine.	**Minutes.**
Time to rough off cut ¼in. thick, 4ft. long, 2½in. wide	—
Time to rough off cut ⅛in. thick, 3ft. long, 12in. wide, &c. ..	—
Time to finish cut 4ft. long, 2½in. wide	—
Time to finish cut 3ft. long, 12in. wide, &c.	—
Total	—
Add ——per cent. for unavoidable delays	—

It is evident that this job consists of a combination of elementary operations, the time required to do each of which can be readily determined by observation. This exact combination of operations may never occur again, but elementary operations similar to these will be performed in differing combinations almost every day in the same shop. A man whose business it is to fix rates soon becomes so familiar with the time required to do each kind of elementary work performed by the men, that he can write down the time from memory. In the case of that part of the work which is done by the machine, the rate-fixer refers to tables which are made out for each machine, and from which he takes the time required for any combination of breadth, depth, and length of cut.

(49) While, however, the accurate knowledge of the quickest time in which work can be done, obtained by the rate-fixing department and accepted by the men as standard, is the greatest and most important step towards obtaining the maximum output of the establishment, it is one thing to know how much work can be done in a day, and an entirely different matter to get even the best men to work at their fastest speed or anywhere near it.

(50) The means which the writer has found to be by far the most effective in obtaining the maximum output of a shop, and which, so far as he can see, satisfies the legitimate requirements, both of the men and the management, is the *differential rate system of piece-work*. This consists briefly in paying a higher price per piece, or per unit, or per job, if the work is done in the shortest possible time, and without imperfections, than is paid if the work takes a longer time or is imperfectly done.

(51) To illustrate:—Suppose twenty units or pieces to be the largest amount of work of a certain kind that can be done in a day. Under the differential rate system, if a workman finishes twenty pieces per day, and all of these pieces are perfect, he receives, say, 15 cents per piece, making his pay for the day 15 × 20 = 3 dols. If, however, he works too slowly and turns out, say, only nineteen pieces, then, instead of receiving 15 cents per piece he gets only 12 cents per piece, making his pay for the day 12 × 19 = 2·28 dols., instead of 3 dols. per day. If he succeeds in finishing twenty pieces, some of which are imperfect, then he should receive a still lower rate of pay, say, 10 cents or 5 cents per piece, according to circumstances, making his pay for the day 2 dols., or only 1 dol., instead of 3 dols.

(52) It will be observed that this style of piece-work is directly the opposite of the ordinary plan. To make the difference between the two methods more clear: supposing, under the ordinary system of piece-work, that the workman has been turning out 16 pieces per day, and has received 15 cents per piece, then his day's wages would be 15 × 16 = 2·40 dols. Through extra exertion he succeeds in increasing his output to twenty pieces per day, and thereby increases his pay to 15 × 20 = 3 dols. The employer, under the old system, however, concludes that 3 dols. is too much for the man to earn per day, since other men are only getting from 2·25 dols. to 2·50 dols., and therefore cuts the price from 15 cents per piece to 12 cents, and the man finds himself working at a more rapid pace, and yet earning only the same old wages, 12 × 20 = 2·40 dols. per day. What wonder that men do not care to repeat this performance many times!

(53) Whether co-operation, the differential plan, or some other form of piece-work be chosen in connection with elementary rate-fixing, as the best method of working, there are certain fundamental facts and principles which must be recognised and incorporated in any system of management, before true and lasting success can be attained, and most of these facts and principles will be found to be not far removed from what the strictest moralists would call justice.

(54) The most important of these facts is, that *men will not do an extraordinary day's work for an ordinary day's pay*, and any attempt on the part of the employers to get the best work out of their men and give them the standard wages paid by their neighbours will surely be, and ought to be, doomed to failure.

(55) Justice, however, not only demands for the workman an increased reward for a large day's work, but should compel him to suffer an appropriate loss in case his work falls off either in quantity or quality. It is quite as important that the deductions for bad work should be just, and graded in proportion to the shortcomings of the workman, as that the reward should be proportional to the work done. The fear of being discharged, which is practically the only penalty applied in many establishments, is entirely inadequate to producing the best quantity and quality of work; since the workmen find that they can take many liberties before the management makes up its mind to apply this extreme penalty.

(56) It is clear that the differential rate satisfies automatically, as it were, the above conditions of properly graded rewards and deductions. Whenever a workman works for a day—or even a shorter period—at his maximum, he receives under this system unusually high wages; but when he falls off, either in quantity or quality, from the highest rate of efficiency, his pay falls below even the ordinary.

(57) The lower differential rate should be fixed at a figure which will allow the workman to earn scarcely an ordinary day's pay when he falls off from his maximum pace, so as to give him every inducement to work hard and well.

(*To be continued.*)

Leeds Association of Engineers.—The annual meeting for the election of officers was held April 16th. The following were elected to serve for the ensuing twelve months:—President, Mr. James Bowers; vice-president, Mr. William Sheldon; committee, Messrs. T. Craister, Robert Lupton, and Alfred Towler; librarian, Mr. W. J. Dickinson; auditor, Mr. A. J. Balkwill; treasurer, Mr. W. H. Drake; hon. secretary, Mr. George W. Blackburn. A vote of thanks to the retiring officers was passed, on the motion of Mr. J. C. Jefferson, seconded by Mr. Alfred Atkinson, and acknowledged on their behalf by Mr. Samuel Thornton, the retiring president.

---

* Presented at the Detroit meeting of the American Society of Mechanical Engineers.

* The writer's knowledge of the speed attained in the manufacture of textile goods is very limited. It is his opinion, however, that owing to the comparative uniformity of this class of work, and the enormous number of machines and men engaged on similar operations, the maximum output per man and machine is more nearly realised in this class of manufactures than in any other. If this is the case, the opportunity for improvement does not exist to the same extent here as in other trades. Some illustrations of the possible increase in the daily output of men and machines are given in paragraphs 78 to 82.

RAILWAY MATTERS.

It is stated that a new express service from London to Paris, and *vice versâ*, *viâ* Folkestone and Boulogne, has been finally decided upon. It will be inaugurated on July 1st. Leaving London at half-past three and Paris four at p.m. respectively, the passengers will arrive at their destinations about half-past eleven at night.

It is stated that the North Metropolitan and the London Street Tramways have jointly agreed to sell their undertakings to the London County Council at once, and to pay a sum of £600,000 for the fourteen years' lease to be granted to them. This will be equivalent to 9 per cent. on the capital outlay. The committee of the Council have completed negotiations for leasing other tramways, which will return 5 per cent. on the capital outlay.

In Victoria a gauge of 5ft. 3in. has been adopted, while in New South Wales that known as the standard gauge, 4ft. 8½in., has been taken. The private line, Deniliquin to Moama —New South Wales—is laid to the Victorian gauge. South Australia has both the 5ft. 3in. and the 3ft. 6in. In Queensland the narrow gauge of 3ft. 6in. has been adopted throughout, and in Western Australia both the Government and private lines are laid on the narrow gauge of 3ft. 6in.

The many accidents to railway servants have caused frequent expressions of regret in the reports of the Board of Trade. Particulars are given in the recent returns as to the different classes concerned in the accidents during the past year. Of the 442 who were killed, 117 were men employed on the permanent way, 49 were porters, 37 were labourers, 35 were brakesmen and goods guards, 30 were firemen, 26 were shunters, and 22 were engine drivers. In a section of the report which enumerates the accidents to servants in the employ of railway companies or contractors, such accidents being caused by the travelling of trains or the movement of vehicles used exclusively upon railways, it is shown that 75 were killed and 648 injured during shunting operations. Sixteen were killed and 331 injured while coupling or uncoupling vehicles, and 93 were killed while walking or standing on the line on duty.

The record of train accidents in the United States in February includes 34 collisions, 91 derailments, and four other accidents, a total of 129 accidents, in which 37 persons were killed and 107 injured. These accidents are classified by the *Railroad Gazette* as follows:—Collisions: Trains breaking in two, 2; misplaced switch, 3; failure to give or observe signal, 6; mistake in giving or understanding orders, 3; miscellaneous, 5; unexplained, 15; total, 34. Derailments: Broken rail, 3; defective bridge, 2; defective switch, 1; broken wheel, 7; broken axle, 8; broken truck, 3; fallen brakebeam, 2; boiler explosion, 1; misplaced switch, 1; careless switching, 1; unfastened switch, 1; animals on track, 1; landslide, 5; washout, 2; flood, 1; malicious obstruction, 2; accidental obstruction, 4; ice, 1; wind, 1; unexplained, 42; total, 91. Other accidents: Boiler explosion, 1; broken side rod, 1; various breakages of rolling stock, 2; total, 4. Total number of accidents, 129.

On Monday, at the House of Commons, a deputation, representing the ratepayers of Sligo and Enniskillen, waited upon Mr. Hanbury, Secretary of the Treasury, for the purpose of opposing the proposed purchase of the Sligo, Leitrim, and Northern Counties Railway of Ireland by the Great Northern and Midland Railway Companies of Ireland. Sir Henry Gore Booth laid before Mr. Hanbury a short history of the formation of the line, and explained how it came to be in financial difficulties, as a result of which the Treasury, who had found some portion of the capital, applied about two years ago for tenders for the purchase of the line. The Great Northern and Midland Companies replied offering to purchase it for about £130,000, which was about one-third of the original cost of the undertaking. Sir Henry strongly urged the Treasury not to accept the offer, chiefly on the ground that the sale would result in a monopoly, with the evil consequences of increased rates, and of preventing the development of the district. Mr. Hanbury, in the course of a brief reply, said he was strongly in favour of not selling the line. He should be glad to receive details of the scheme of reconstruction, to which he would give his best attention.

The importance of railways in the development of Australia cannot be over estimated, as owing to the absence of natural waterways, almost all the traffic from the interior has to be carried by rail. The four principal cities of the Colonies are in direct railway communication; and viewed from the "population per mile of line" point, Australia can boast even now of being better served by its railways than any country in the world. New South Wales has at present 146½ miles of railway under construction; Victoria, 15½ miles authorised; Western Australia is pushing on with 382 miles of additional lines, 57 of which were to be opened in December last. The railways of Australia practically represent the assets for the national debts of each Colony. It is agreed that to a certain extent the railway administration should be separated from politics; the construction and direction of new lines may well be left to Parliament to determine, but the management of the lines and control of the railways daily working are matters for skilled and capable railway managers, untrammelled by the exigencies that political consideration would often cause to influence the political mind. These views have been given effect to in Victoria, South Australia, New South Wales, and Queensland, which provided to a certain extent for the management of the railways on commercial as separate from political lines. Each system was placed under the control of three commissioners, who had large powers to administer free from political interference, and the generally expressed opinion is that the system worked well. Victoria, however, amended her Railway Act of 1883 by limiting the powers of the Commissioners, and giving the Minister for Railways of the day greater power to interfere in the management. But this change has not brought about the desired result, and the Act is being again amended.

Four persons killed, a dozen seriously injured, and fifty others hurt more or less severely, is, says the *Railroad Gazette*, the result of the collision of electric cars at St. Louis, on March 8th. Recklessness, either of officers in failing to prescribe rules, or of motormen, generally ignorant, in carrying them out, is apparent on electric railroads all over the country, and collisions or runaways illustrating it occur every few days; but fortune favours the fatuous, fatalities are few, and the lessons bearing on future practice seem not to be heeded. Here, however, is a flagrant case, in many respects typical. The road—the St. Louis and Kirkwood —runs, a part of the way at least, on its own right of way, separate from the street, so that cars can be run as fast as may be desired. Grades are steep and cars pretty heavy, so that high speed down grade is easily made. The *Republic* reporter timed several cars and found them making forty miles an hour. The manager has had no experience on standard railroads, entrusts cars to men hired without adequate inquiry, and has no printed regulations. A written memorandum of some kind is given to motormen. Ruling trains are required to wait three minutes at meeting points, and those going in the opposite direction indefinitely; but it appears that this last provision is modified most of the time so as to permit an inferior train to proceed cautiously after ten minutes. Trains appear to be run in this way without any supervision, and inferior trains are in the habit of "stealing switches" whenever it seems desirable. An attempt to do this—to reach the next meeting point before the ruling train gets there, while the whereabouts of the latter is wholly unknown—was what caused this collision. To cap the climax, says the *Gazette*, the passengers on these forty miles an hour trains are allowed to crowd the front platforms of the cars.

NOTES AND MEMORANDA.

The weekly return of the Registrar-General shows that the deaths registered last week in 33 great towns of England and Wales corresponded to an annual rate of 19·0 per 1000 of their aggregate population.

In London 2836 births and 1654 deaths were registered, or 87 above and the deaths 27 below the average numbers in the corresponding weeks of the last ten years. The annual death-rate per 1000 from all causes, which had been 17·9, 17·9, and 20·3 in the preceding three weeks, fell again last week to 19·4

Chloride of lime, Traube has pointed out, provides the means of obtaining a germ-free drinking water, and has proved its utility by practical experiments. His tests were not conducted with pathogenic germs, though he concluded from his experiments that, used in the proportions he advocates, it would be fatal to all kinds of bacilli.

Sternberg and Delettre have, according to the *Moniteur de la Ceramique et de la Verrerie*, invented a new process for the production of refractory material. They claim that by adding 10 to 15 per cent. of asbestos, either fibrous or pulverised, the material is made more fire-proof and durable. The addition of asbestos is made while the clay, or whatever earth is used, is being mixed. Bricks produced from this material are said to prove excellent in the construction of converters, retorts, melting pots, &c.

In the French journal, *L'Industrie Velocipédique*, experiments by M. Wallington with ignition tubes for gas engines are referred to, and the mixture of materials for porcelain tubes which he has found to be best is given. It is as follows: Kaolin 62 parts, 4 chalk, 17 sand, and 17 feldspar. Each of these constituents is ground in water separately, and these waters, whilst all the fine particles are carried in suspension, are mixed together and decanted into a settling tank. After subsidence, the fine material obtained is moulded into tubes, which are at first air dried. They are then baked in clay cylinders for about fifteen hours with a wood fire. The cost is high, but the durability is high also.

Referring to statements advanced at the 1895 meeting of the Bavarian Society of Applied Chemistry—*Chem. Zeti.* 19, 1452—Mr. R. Kissling points out that the amount of paraffin in burning oils is very slight, and can, in any case, only affect the consumption of the oil—not its illuminating power. In connection with the assertion that Ohio oil containing a large proportion of sulphur is now in the market, necessitating the examination of such oil for the detection of sulphur, he remarks that those who ought to know deny that refined Ohio oil is dealt in in Germany, but that even if it be, the desulphurising processes this oil undergoes in refining render it undistinguishable from the Pennsylvania oil, containing but little sulphur.

The velocity of an earthquake-wave within a short distance from the epicentre is so difficult to ascertain on account of the large error resulting from a small error in the recorded times, that all estimates with an approach to accuracy are of value. In the Brescian earthquake of November 27th, 1894, good time-determinations were obtained at ten stations, all within 445 kiloms. from the epicentre. Assuming the velocity to be uniform in all directions, Dr. M. Baratta calculates it to be 1·411 kiloms. per second. Taking account of the nature and extent of the rock traversed by the earth wave, he also finds the average velocity to be ·782 kiloms. per second in alluvium, and 1·569 kiloms. per second in the older and more coherent rocks. The large scale experiments made at Holyhead by Mallet gave these results for sand, slightly discontinuous and discontinuous rocks. They were published in the "Transactions" Royal Society in 1873.

At a recent meeting of the Philadelphia Academy of Natural Sciences, General Isaac J. Wistar made a communication on the apparent capricious distribution of iron oxide as colouring matter in the rocks of the anthracite coal region. At several points, apparently, the accessible supply of iron was exhausted by complete distribution in the strata under process of deposit with intermediate and subsequent periods during which new supplies appear from some source not yet clearly explained. Professor A. P. Brown stated that it had been suggested by Russell that the red colour of certain formations may have originated from the subaërial decay of iron bearing rocks, and the subsequent deposit of this material as sediment forming the red rock. As far as the ash of coal is concerned, it is probable that the colour is due to the way in which pyrites is contained either in the coal itself or in the slate adjoining. Coal containing separable pyrites would give white ash, while if the pyrites is intimately mixed in the coal the ash will be red.

A novel series of exepriments is in progress at Wesleyan University, Middletown, Connecticut, to determine the nutritive and caloric value of food, and many other questions relative to nutrition and other vital processes. Quoting some source not named *Nature* says:—"For this purpose a calorimeter is employed, consisting of a copper-lined box, measuring inside 7ft. by 4ft. by 6½ft., thus giving 182 cubic feet of air, within which space a man is confined for several days at a time. It is fitted with glass windows of three thicknesses. Fifty litres of air per minute are pumped in. Food is passed in three times a day through an air-tight tube, and is carefully weighed, as are all the exudations and excretions, and the quantity of heat is measured. A telephone enables the subject to converse with the outer world. The experiments are conducted by Pro. Wm. O. Atwater, and the expense is shared by the Department of Agriculture of the United States Wesleyan University, and the Stores Experiment Station at New Bethel. A careful record is kept of every action of the subject—of his hours of sleep, minutes of exercise, respiration, appetite, &c. To this end there are two watchers and two assistants, a watcher, who is a professor in the university, and an assistant being constantly present."

The Department of State in Washington has published reports from Magdeburg, Dusseldorf, Frankfurt, and Stettin dealing with the slag cement trade. This cement, it seems, is made by mixing pulverised hydrate of lime with basic blast furnace slag, which has been granulated, dried, and reduced to powder by grinding. It is used for certain purposes as a substitute for Portland cement, for it is about 20 per cent. cheaper, and being of lower specific gravity, "spreads farther," so that on the whole the economy in using it is 30 to 40 per cent. It is also alleged that the mortar is more tenacious and elastic, and thus is more suitable for the foundations of bridges and other structures liable to unequal strain or to the shock of passing trains or vehicles. It was originally suggested by the excellent cement obtained from mixtures of hydraulic lime and *puzzolani* or pulverised lava, which was first produced in Germany in 1863. The essential element in basic slag for making cement is silicic acid in proper proportions, and then this must be "live" and in a condition to unite readily and firmly with the lime, while the slag must contain a due proportion of magnesia and not an excess of some impurity which will resist the combination and sooner or later cause crumbling or disintegration. In Western Germany there is only one small district—in the Saar Valley—where slag of perfect quality is produced, and here the slag cement manufacture is concentrated in the hands of two firms. This cement seems to be regarded with some suspicion by engineers, who will only use it when they know where, by whom, and from what materials it has been manufactured. When of good quality it may be used with advantage where the work will always be moist and protected from the sun. The consul at Magdeburg says the industry is dying out in Germany owing to the opposition of Portland cement, lack of support from the Government, and stagnation in the building trade; a factory opened at Stettin some years ago failed. In Germany it is generally called puzzolan cement.

MISCELLANEA.

Messrs. Earles' Shipbuilding and Engineering Company, of Hull, have received an order from the Admiralty to construct two 30-knot torpedo boat destroyers.

Even experienced carriers get into trouble under the present traction on roads regulations. At the Mansion House the Fardell Traction Haulage Company, Limited, were fined in all £10, with £10 10s. costs, for having on five occasions in March last used a traction engine in the City without being licensed by the Corporation under the Highway Act.

In reply to a correspondent, writing on high and low tension currents, the Board of Trade replied that they have been informed of nine cases of fatal accidents to employés at generating or transforming stations where high-pressure alternating currents are used, but that no instances have been reported in the case of low-pressure continuous currents. It may also be true that the Board of Trade have heard of the drowning of many people in the sea, but none in street gutters.

The new American torpedo boats or destroyers—for they are of 180 tons displacement—differ, according to the *Naval and Military Record*, from most other craft of their kind in that they have built-up forecastles, very much like our "catchers" of the Alarm, or 810-ton type. These forecastles gave them a freeboard forward of no less than 12ft. 6in., and should render them excellent boats for sea work. The speed is to be 26 knots, with 3200-horse-power and 395 revolutions. The armament consists of four 1-pounders and three torpedo-tubes, one being astern and two *en echelon* nearly amidships. There are three funnels and two conning towers.

A Sholapur correspondent writes to the *Bombay Gazette*:—"As a sign of the times, we hear that a patriotic and leading native of Pandurpur has opened a shop for the sale of country-made mill and hand-woven cloths in that town, and laid in a stock of over ten thousand rupees worth of cotton and woollen fabrics, in order to help the masses to patronise Indian industries only. His example is being followed in numerous other places. As these patriots are mostly wealthy men, content with the smallest profits to merely cover cost, it is probable that Manchester has raised a hornet's nest, and given an impetus to Indian, Chinese, and Japanese trade which it never contemplated, and from which it will suffer in the end."

Some floods prevention works are much wanted in Canada. Damage amounting to a million dollars has been done in the eastern townships by floods, the worst which have been experienced for twenty years. The town of Richmond and part of Sherbrooke have been submerged, and hundreds of families have been driven from their homes. Many mills and factories on the banks of the St. Francis River have been swept away, and the Quebec and the Central and Drummon County Railways have been crippled, iron bridges having been demolished. Twenty-four houses were swept away from St. Anne's and Isle de Grace on the 20th inst. The loss of life is fortunately very slight considering the serious character of the flood.

On January 7th, 1890, the Egyptian Government, having received the assent of the European Powers, issued a decree levying a tax of 1¼ millièmes—about 3s. 10d.—per ton on shipping entering and leaving the harbour, to become payable when a new pass having 300ft. width and 30ft. depth should be completed. This is now officially declared as accomplished, and that the tax will be levied from May 1st next, when compulsory pilotage dues will be abolished. The expense of excavating the pass was estimated at £60,000, to be borne equally by the Government and shipping, the latter to contribute £3000 additional for two years' interest. The tax is to cease absolutely so soon as it has realised the amount of £33,000 with 5 per cent. interest, and a special half-yearly report is to be published showing the receipts. The *Times* Cairo correspondent says the Government bears the expense and responsibility of keeping the new pass lighted at all times, and it is already freely used by ships entering and leaving during the night.

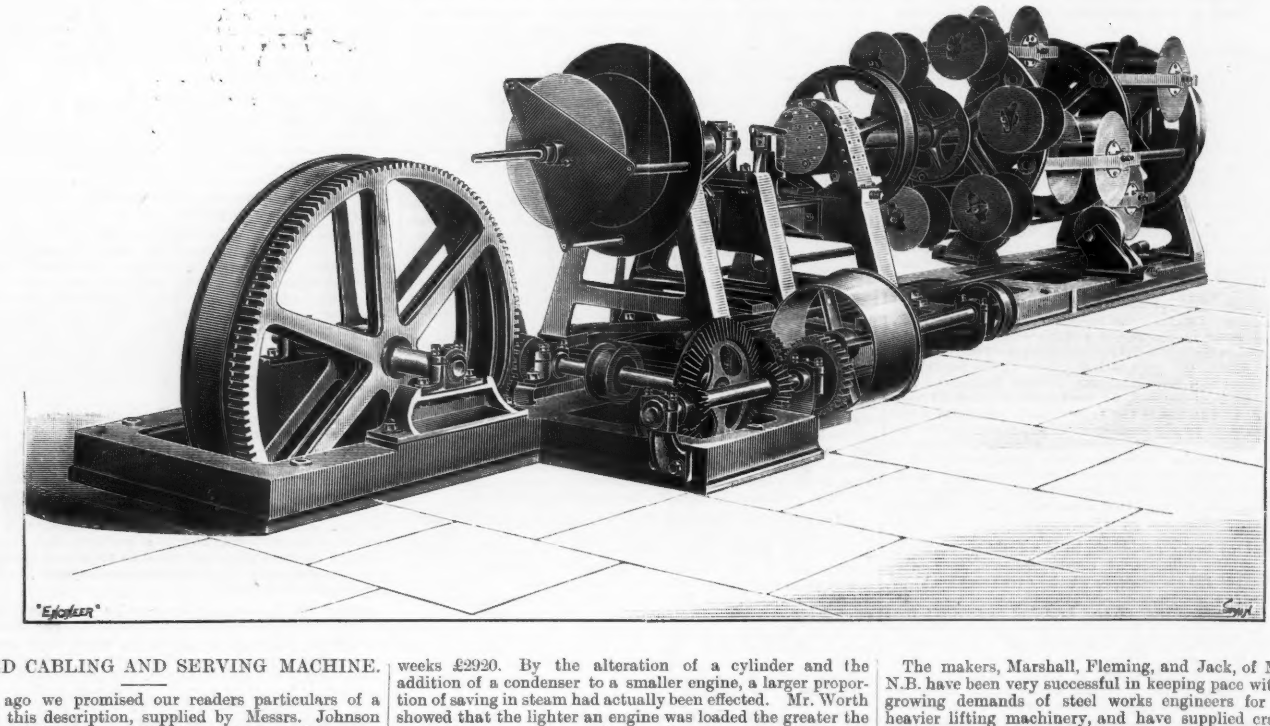
It is stated, the *Dover Standard* is authoritatively informed, that the Kent Coalfields Syndicate have definitely entered into a contract with a firm of mining engineers in the north of England to sink two colliery shafts at Hongham, two miles west of Dover. The shafts are to be 20ft. in diameter, and are to be sunk within twelve months. It is intended to make further borings. The syndicate consists of the following gentlemen:—Mr. Philip Stewart Mackenzie Arbuthnot, West Hoathley, Sussex; Mr. Richard Berens, St. Mary Cray, Kent; Mr. George Frederick Fry, Dover Harbour Commissioner; Mr. Frederick Pitts, County-chambers, Cornhill, London; and Sir Henry Beyer Robertson, Palé, Merionethshire. The experts calculate that there is sufficient coal in the measures already discovered, taking an area of not more than 6000 acres, to supply about 3000 tons a day for seventy years. The coal-bearing district in Kent is estimated at about 150 miles in length by about five or six miles in breadth.

A great engineering work of immense importance to the city of Venice has just been completed. Fifty-eight years ago, in order to prevent the damage caused by the occasional overflowing of the river Brenta, the Austrian Government, on the recommendation of the celebrated engineer Paleocapa, carried out certain works by which the months of that river were carried into the Chioggia Lagoon, some distance south of their original outlet. Since then the alluvium brought down by the river has threatened to convert a portion of Chioggia Lagoon into a fever-breeding swamp; and also to cause serious damage to the whole Venice Lagoon by silting. It was accordingly decided to construct a new channel for the Brenta, sixteen kilometres in length, giving the river a direct outlet into the sea near Brondolo, still further south. The scheme, which was estimated to cost eight million lire, and was begun in 1884, has now been brought to a successful conclusion. The new channel, by means of subsidiary canals, also provides a fresh outlet for the Bacchiglione and other rivers formerly flowing into the Venice Lagoon.

In the course of a lecture on "Recent Chemical Progress," given on the 16th inst. at the Royal Institution, Professor Dewar, F.R.S., commented on the great future opened out to synthetical chemistry by the employment of the temperature of the electric arc. Some of the most interesting results had been obtained from the electric furnace by the French chemist, M. Moissan, in the shape of carbides, stable bodies produced by the combination at high temperatures of carbon with various metals. Many of these carbides were decomposed by water, the hydrogen of the water combining with the carbon to form hydrocarbons. Thus with water some carbides, such as that of calcium, gave acetylene; others, like that of aluminium, gave marsh gas, while others again gave these and other gases, and, what was most wonderful, liquid petroleums. It was a curious fact that many years ago Professor Mendeleef speculated that the only reason for the immense localisation of petroleum at Baku was that it was being generated there—he suggested by the action of water on carbides. His idea was rather smiled at then, but now it was his turn to smile. When acetylene was heated to a dull red heat, it was polymerised to benzene. Benzene was the basis of all the new modern colours, and thus by three direct stages we were able to reach the nucleus of all the colours hitherto manufactured from coal-tar products. First there was the combination of lime and coke in the electric furnace; secondly, the decomposition of the carbide thus formed by water; and thirdly, the transformation into benzene of the resulting acetylene by means of heat. Professor Dewar concluded by briefly discussing some of the properties of acetylene, explaining, among other things, the cause of its extraordinarily great luminosity as due to its peculiar endothermic structure.

COMBINED CABLING AND SERVING MACHINE

MESSRS. JOHNSON AND PHILLIPS, CHARLTON, ENGINEERS



COMBINED CABLING AND SERVING MACHINE.

Some time ago we promised our readers particulars of a machine of this description, supplied by Messrs. Johnson and Phillips, of Charlton, to H.M. Postal Telegraph Department, for cabling their gutta-percha covered cables, and at the same time serving them with compounded tape. This machine, which we now illustrate, is arranged for cabling seven wires, *i.e.*, laying six wires round one, and at the same time laying a yarn in the recess formed between each pair of wires, so that when the cable is taped it forms a more perfect round.

The machine is erected on a strong cast iron bed-plate, and the six wire bobbins—arranged in two bays—are carried in forged wrought iron fliers between three discs, the third disc also carrying the six yarn bobbins. The central hollow steel shaft runs in a large gun-metal stepped bearing at one end, and the "lay-head" end and the central disc run on anti-friction rollers. The draw gear is driven from the "lay-head" end of this shaft by means of a belt driving on to a countershaft carried from the bed-plate of the machine. The motion is transmitted to the draw-through drum by means of spur and bevel gearing, change wheels being provided to give the requisite length of "lay" for the different sizes of wires. The taping head is designed to serve various widths of tapes, and for that purpose is driven by means of coned pulleys, which allow the "lay" and "lap" of the tape to be adjusted very minutely.

The bobbin of tape, as will be seen, is arranged concentrically with the cable, the tape being led from the bobbin by means of a series of rollers, &c., down through a slotted guide on to the cable. The wire bobbins are each arranged to hold one mile of gutta-percha covered wire, and the yarn and tape bobbins respectively hold sufficient tape to "worm" and "serve" this length of cable. The diameter of the tape bobbin is 21in.; the radius described by the taping head, measured over the guide rollers, is 16in., and the speed of this head is about 500 revolutions per minute. The central hollow shaft is 3in. diameter, and runs in large gun-metal stepped plummer blocks, having bearings two and a-half diameters long. All the bobbins are provided with means for adjusting the tension on the various wires, yarns, &c., as may be desired. The finished cable is led from the draw-through drum on to a receiving drum placed a few feet distant from the cabling machine, from which it is driven by means of a belt. This apparatus is provided with an automatic guiding-on and flaking gear, which is not shown in the illustration.

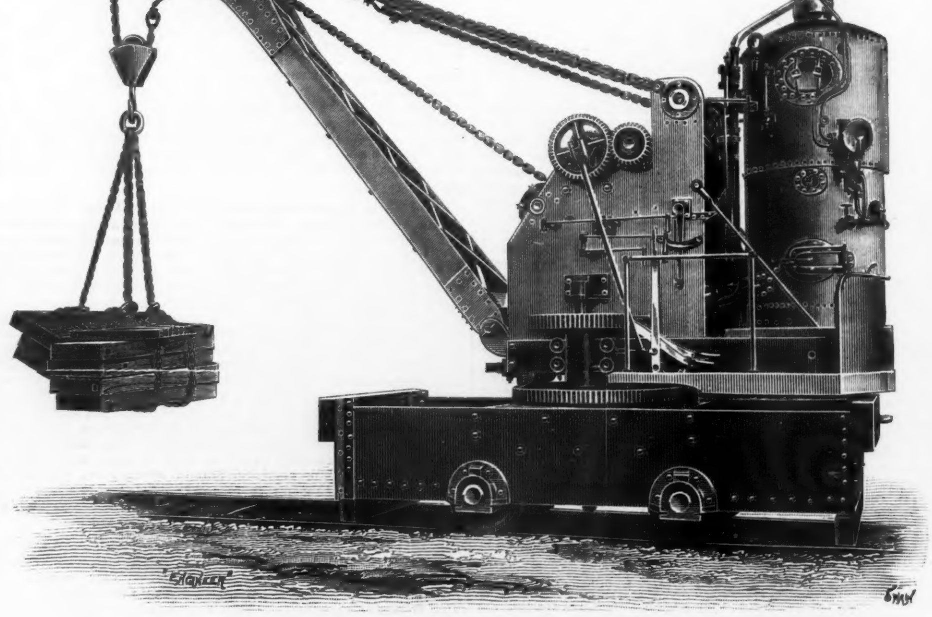
Besides the above-described machine we understand that Messrs. Johnson and Phillips have supplied H.M. Postal Telegraph Department with a four-wire combined cabling and serving machine, all complete with the necessary bobbin winders, swifts, and automatic winding and coiling gear, for making the finished cable up into coils, and have fitted it up at the Mount Pleasant factory.

CONDENSERS FOR ROLLING MILL ENGINES.

Mr. Robert J. Worth, of Worth, Mackenzie, and Co., Limited, engineers, Stockton-on-Tees, at the monthly meeting of the Middlesbrough District Association of Foremen Engineers and Mechanical Draughtsmen, read a paper on "The Application of Condensers to Rolling Mill Engines." He remarked that, owing to the fact that steel was rapidly superseding iron, the rolling mills no longer had that superabundance of steam which formerly was raised by the waste heat from the puddling furnaces. Economy of steam in rolling mill engines was formerly a matter of no consequence, but now it was becoming one of primary importance. The difference between a rolling mill with engines of the type usual in the North of England, and a mill laid out on the best system for economy of steam was, he believed, just the difference between one that barely paid and one that returned a good profit to the owners. Thus, if an engine of the usual size, with a pair of 42in. cylinders and 5ft. stroke reversing, were taken, the difference in the steam consumption between the ordinary type and a fairly economical type would be equivalent to a saving of about 5700 lb. of coal per hour during the time the engine was actually running. If the engine ran six hours per shift, and ten shifts per week, and the value of the coal delivered were 8s. per ton, there would be a saving of £61 per week, or on a year of forty-eight weeks £2920. By the alteration of a cylinder and the addition of a condenser to a smaller engine, a larger proportion of saving in steam had actually been effected. Mr. Worth showed that the lighter an engine was loaded the greater the saving in steam consumption, and, as in a "pull over" or "crab reversing" mill, the time during which the engine was running empty or lightly loaded formed a very large proportion of the total running, the saving with mills of this type and with engines well up to their maximum work would be very great. There were circumstances, however, when the saving effected by the use of a condenser was greater and more important than those mentioned, and these were when the engine was under its work, and when the workmen, in consequence, had to wait a considerable time for the engine to get up speed. The additional power and speed would generally be from 40 to 50 per cent., and that would represent a great saving in labour. The main engines using less steam would leave more for the auxiliary engines, and a more regular pressure would thus be maintained in the boilers. The author recommended Korting's ejector condenser on account of its great simplicity, the absence of any working parts, and the fact that it needed no attention.

LOCOMOTIVE STEAM CRANE.

The above engraving illustrates a handy size of locomotive steam crane, one of a class specially designed for use in steel works; it lifts and travels with 10 tons at 14ft. radius on 4ft. 8½in. gauge of rails. As very quick speeds are required, combined with immunity from breakages, all parts are made with an ample margin of strength. The framing of body and carriage is constructed of heavy steel plates, and the gearing throughout is of Siemens cast steel. The jib is swan-necked, to give plenty of clearance for the load at a short radius and under limited head room, and the radius is adjustable by worm gear from the engines. The carriage is provided with feet, so that should the crane leave the rails it cannot sink or overturn.



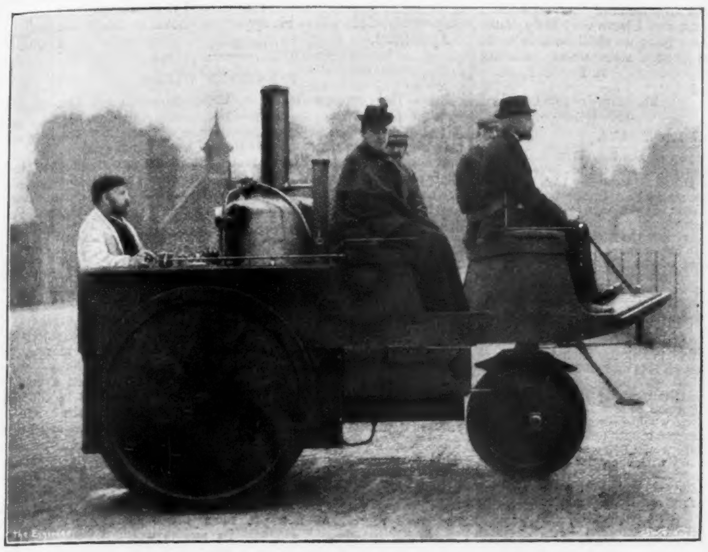
LOCOMOTIVE STEAM CRANE, MESSRS. MARSHALL, FLEMING, AND JACK, ENGINEERS

The makers, Marshall, Fleming, and Jack, of Motherwell, N.B. have been very successful in keeping pace with the ever-growing demands of steel works engineers for faster and heavier lifting machinery, and have supplied cranes of the above type for loads up to 20 tons to leading steel makers.

The Crystal Palace School of Engineering.—On Friday last Mr. A. T Walmisley, M. Inst. C.E., engineer to the Dover Harbour Board, distributed the certificates obtained during Easter term by students at the Crystal Palace School of Practical Engineering. In the course of his address he said that they had to congratulate themselves on the results of the first term of their twenty-fourth year. Very few people had any idea of the amount of educational work carried on at the Palace. Old students from that school were to be found exercising their profession all over the world, and no small portion of the success which had been attained was due to the personal influence which the principal, Mr. J. W. Wilson, had exercised over the 1172 students who had passed through the school since its foundation. In the first term of 1872, when the school was established, they had fifteen students. This term they numbered seventy-one. They demanded an entrance examination as a test of proficiency in general education. The Institution of Civil Engineers did the same for their class of students since the year 1889, when the Institution had 967 students on their books. The students' class at the Institution was established in 1867. Of course many had become transferred to corporate membership upon attaining the proper age, and the present number of students was 877. He strongly recommended all those who wished to come to the front in the profession to join the Institution of Civil Engineers as students as soon as they could, and felt sure the technical training they received at the Palace would prove an additional testimonial for their nomination, although the Council of the Institution of Civil Engineers simply demanded proof of a sound general education, and did not specially insist upon proof of previous technical education. He advised the students not to run away with the idea that what they had learned was incapable of improvement, and he strongly urged them not to put blind faith in formulas, but to examine each case on its merits. At the close of the distribution, Mr. G. T. Rait, chairman of the Palace Company, thanked Mr. Walmisley on behalf of the directors, and the proceedings terminated.

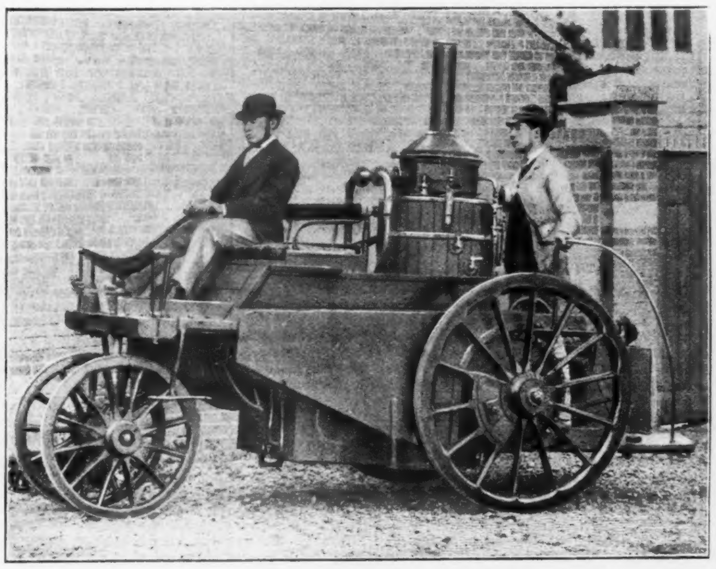
SOME MORE STEAM CARRIAGES.

THE two steam carriages illustrated by the engravings now published are of considerable interest, as showing the direction which design took from twenty to thirty years ago, or a quarter of a century after the very different designs of Hancock, Gurney, James, Hill, Macerone, Church, and others had been given up for various reasons, though they had been perfectly satisfactory as indicating the practical lines on which coaches could be thereafter built. Reasons other than mechanical or structural caused the cessation of efforts in this direction, and except spasmodically little was done for a quarter of a century, and then most of the designs were rather of the carriage for a steam engine and boiler than a comfortable passenger carriage operated by a steam engine. The engine was in many cases much better from the steam engine designer's point of view, but in nearly all cases the useful work done by Hancock, Gurney, and others, with reference to the boiler, was ignored, and no real progress from the carriage point of view was made, the weight of the engine and boiler and gear being excessive, much of it being due to the boiler, which in most cases was either the modern locomotive or the then modern vertical boiler, with large unstayed or unbalanced surfaces requiring heavy plates. Many of these steam carriages of a quarter of a century ago were from the mechanical engineer's point of view successful, and as they played an important part historically they are of interest even now in part as illustrations of what could be done or might be done, and partly as showing what not to do.



MR. NEVILLE GRENVILLE'S STEAM CARRIAGE, 1875

One of these shown by side and end views is of a steam carriage still existing. It was built for Mr. R. Neville Grenville, of Butleigh Court, Glastonbury, in 1875, by Messrs. T. Cooke and Sons, York. The boiler is a Shand and Mason cross-tube steam fire-engine type. It had a single inverted cylinder bolted outside of the boiler 5in. diameter by 6in. stroke. But this was found unsatisfactory, and was altered to two cylinders of the same size, and geared to half the original speed, and placed horizontally, the ratio of crank shaft to driving wheels being now 4 to 1. The driving wheels are 4ft. diameter with 3in. tires, and are solid disc wheels of teak. These, no doubt, are heavy, but the reason they were made so was that Mr. Neville Grenville heard that others had had trouble with spokes working loose. He questions now if this is really the fact, but the disc wheels are very easy to clean. The second motion shaft is linked to the driving axle at the right-hand end, and rises and falls with it by the action of the springs. The left-hand end has a ball-and-socket bearing, so the effect of this is slightly to throw the gear teeth across each other, but in the same plane, so no ill results and no wear are perceptible. In this way the difficulty attaching to the use of springs and gearing is perfectly overcome. The steering wheel is 2ft. 6in. diameter, with a 3in. tire, and works well. At first there was an arrangement for turning the exhaust into the tank when necessary; but this was not wanted, and, as it was at times inconvenient, it was taken off, and an exhaust tank and feed heater put on instead, the water from the condensed steam running back into the water tank. The boiler is fed by a pump and by an injector. The weight with coal and water is 45 cwt. The tank holds 55 gallons. The boiler heating surface is fire-box 13ft., tubes 16ft.; total, 29 square feet. The grate area is 2½ square feet. The carriage is still in working order, and Mr. Grenville ran it in the last few weeks 120 miles. The following is the account of the last two runs from Mr. Neville Grenville's diary, which will give an idea of what the carriage will do.



MR. KNIGHT'S STEAM CARRIAGE, 1368

Saturday, April 4th, 1896.—"After lunch to Baltonsborough with steam carriage; went to several places there and did my business and back by five. Distance run, seven miles."

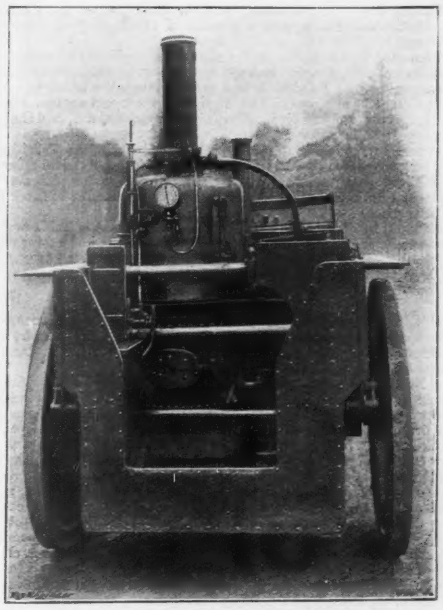
Tuesday, April 7th, 1896.—"Mr. Pinney came at 9.30 a.m., and we started with steam carriage at 9.45, George Mildred with me in front, and Noble firing, Mrs. N. G. and Mrs. Audry with us as far as the Horse and Lion; we on through Glastonbury and to Polsham; stopped there for five buckets of water, and on to Wells, arriving at the Palace at 10.50—ten miles in sixty-five minutes, including stops for horses, water, and at railway level crossing. Called on the Bishop as I promised, and took him and some friends for a run round the Palace. One of them thought I was a bagman come to try and sell the carriage to the Bishop for him to use in inspecting the diocese! Put up at the stables, Pinney and I to County Council meeting. . . . Barstow tells me he has been to London to see autocars, but did not get any satisfaction, so told him to come home on mine. After the meeting Sir R. Paget, Hobhouse, Dyke, Colonel Clarke, and other County Councillors came and had a ride, and were much pleased. Left for home at 4.40, having on board Barstow and Gibbons extra; a good run to Glastonbury; dropped Gibbons at Edgarley at 5.25, and on *viâ* Baltonsborough, stopping a few minutes for five buckets of water; arrived home at 6 p.m. Fourteen miles in eighty minutes, including stoppages and slowing down. Total run out, ten miles; home, fourteen miles; run in Wells, one mile; total, twenty-five miles. Coal burnt, 155 lb., equal about 6 lb. per mile, including getting up steam twice, as being some hours in Wells I let the fire out We need not have taken any water on the road either way, but thought we would be on the safe side. Water used for the twenty-five miles, about fifty-five gallons at most each way, or 1100 lb., not including drain from the feed-heater, which I had no means of measuring."

Mr. Knight's carriage, illustrated by the accompanying engravings, is one to which reference has several times been made, and it further shows the lines on which the designers of a quarter of a century ago chiefly worked. There are some points of interest and of guidance in them, although now we must look upon all these as rather vehicles for an engine, its gear and a boiler, than as a carriage. It was made by Mr. J. H. Knight, of Farnham, and was commenced in 1868. It was first fitted with one cylinder and a fly-wheel, but the difficulty of starting on inclines was considerable, and a second cylinder was added, the ratio of the gearing being reduced to 1 to 4, instead of 1 to 6, which was the ratio as originally arranged with the single cylinder.

The cylinders were 5in. by 7in., and were fitted between two angle irons, which formed the frame of the machine. They were fitted with link motion, the reversing quadrant and the steam lever being on the steersman's right. The steering wheels, 2ft. 8in. diameter, were on a gauge of 2ft., the hind wheels 4ft. diameter and 4ft. 2in. gauge. The steering wheels were moved by a tiller with a cross handle, but the tiller moved through an arc of twice the radius of the steering wheels; the steersman had thus good control over the carriage, and but little muscular effort was required in steering. Only one wheel was the driving wheel, and this was found sufficient for all practical purposes; it was only found to slip on wet grass. In motor carriages with one driving wheel it seems advisable, at least for use in England where vehicles pass one another on the left, to have the driving wheel on that side, for it is sometimes necessary to leave the crown of the road in passing, and if the right wheel be the driver there might be some difficulty in regaining the hard road. The boiler, originally a multitubular, was afterwards altered into a "Field," with about 26 square feet of heating surface. A tank under the engines carried 40 gallons of water, sufficient for six or seven miles' run. Coal for fourteen or eighteen miles was carried. The brake was worked by the stoker; the boiler was fed by one feed pump and a donkey pump; the weight in running order was 32 or 33 cwt. Three people sitting side by side were accommodated on the seat.

In fair running order the speed was eight to nine miles an hour. A small four-wheeled chaise, carrying three passengers, was often towed by it, and except on steep hills it did not appear to make any perceptible reduction to its speed. Unfortunately it was somewhat noisy in running, and a very sharp blast was necessary. To keep steam coal had to be used, as there was not draught enough to burn coke.

After being in use as a steam carriage for three or four years, it was sold. The purchaser converted it into a small traction engine. Writing of it Mr. Knight says:—



MR. NEVILLE GRENVILLE'S CARRIAGE, 1875

"I think this is a fair account. Some of these details are from memory. The carriage was so frequently altered that drawings would only show it as it was once."

HORSELESS CARRIAGE NOTES.

AN interesting lecture on "Horseless Carriages" was delivered on the 10th inst. before the Belfast Philosophical Society at Belfast by Mr. John Brown, the honorary treasurer. The latter part of the lecture dealt with modern horseless carriages, and necessarily with those of German, Swiss, and French make. Mr. Brown exhibited his own Serpollet steam carriage, purchased from M. Doarzan, of St. Omer. At the close of the lecture, Mr. George Andrews moved the following resolution:—"That this meeting approves of the proposed modification of the Locomotive Acts so as to promote the use of mechanically propelled carriages on public roads, subject to suitable provisions for the safety and convenience of the public." Such an amendment of the Acts as the resolution approved was, he considered, necessary. Though all sorts of motors might not be an unmixed benefit to the public, yet he felt, and he thought it was the feeling of the meeting also, that if these machines could be used safely in other countries they could be used with equal safety in this, and though they might be unsuitable for crowded towns, there could not be any reasonable objection to their use under proper provisions in the country districts. Professor Everett seconded the motion. He believed he was right in saying that a measure for the amendment of thy Acts on the lines of the resolution was at present in the wae of being passed in the Lords, and he hoped it would pass the Commons also, as he believed these carriages had a great future before them. The resolution was passed unanimously.

THE letter we publish on another page from Mr. Flood-Page draws particular attention to the questions which concern the construction and working of electrically-propelled vehicles, and no doubt his contentions will be supported by a great number, although the means of economical applications of electricity for this purpose are not very obvious except over a limited field where the many virtues of an electric motor outweigh the disadvantages of accumulators. This field, although limited at present to the short distance runs of vehicles for town and suburban use, will no doubt widen as accumulators are further improved, and as the necessity for the weight which high discharge capacity requires is lessened by improvements in the means of transmission, so that the maximum power used is never much in excess of the mean.

THERE is a question to which Mr. Flood Page does not allude, although it is one which must receive attention, namely, the proposed refusal of permission to allow one vehicle to haul another. It is, perhaps, early in the days of our hoped-for freedom from trammels which restrict mechanical and industrial enterprise in the design and use of self-propelled vehicles as they do in no other country, to ask for more than the Bill now in Parliament proposes to give; but we must not overlook the fact that it may in the first few years of the use of self-propelled carriages be very necessary to be able to make one haul another which has been disabled, or run short of current, or other power source.

THE haulage of a vehicle by a self-propelled carriage or by a separated light motor carriage, is according to present intentions, barred. This is presumably with the object of preventing anything like traction engine or road locomotive trains. With this object most people will sympathise, but it is undesirable it should also prevent the production of a satisfactory motor vehicle, which, though detachable from the passenger carriage or goods van it hauls, may when coupled to it form a complete whole. Such an arrangement offers some advantages and provides the means of using existing carriages, and of having spare motors, so that time occupied in their repairs shall not be idle time for the vehicles also.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

HORSELESS CARRIAGES.

Sir,—I am sending you a cutting from *L'Industrie Vélocipédique*, containing Mons. M. Mallet's account of his inspection of the Cugnot steam carriage, in which you will see he does not give all credit to his "Compatriotes," neither does he give the glowing description one reads from a perusal of the history of Cugnot's carriage.

I am glad to see Mons. Mallet share the credit between Cugnot and Trevithick. Cugnot had the support of the State to carry out his experiments; Trevithick had not, although the latter was one of the greatest pioneers of the high-pressure steam engine, steam road carriage, railway locomotive, traction engine, &c., and similar developments in latter-day use.

It is sad to conceive that such a "grand esprit" as Trevithick should have passed the latter years of his life in poverty and misery, and saved a pauper's funeral by subscription of his shopmates, and—as I am informed—without a stone or monument to mark his resting place.

I should be glad to see a subscription raised for a suitable monument to be erected in honour of the great inventor of motor road vehicles.

Chas. T. Crowden.

Beeston, Notts, April 10th.

"La voiture de Cugnot.

"M. Mallet, ingénieur est allé examiner l'ancètre de nos automobiles actuelles, le voiture de Cugnot, remisée au Conservatoire des Arts et Métiers, et rend compte de sa visite, comme suit, dans le *Bulletin de la Société des Ingénieurs civils de France.*"

"Nous ne cacherons pas que nous avons été profondément étonné. Certes, ce qui concerne le véhicle et même la machine proprement dite n'est pas mal combiné, surtout si on tient compte de l'époque et du peu d'expérience de l'auteur, mais la partie capitale, la chaudière, laisse tout à désirer.

"On a fréquemment signalé les mauvaises proportions du générateur, la disposition peu favorable du foyer, le peu de résistance de la chaudière pour soutenir l'effet de la vapeur, &c., mais ce n'est pas tout; dans la machine qui est au Conservatoire, et qui est, dit-on, la seconde machine de Cugnot—nous ignorons totalement comment était faite la première—il est absolument impossible de comprende comment on aurait pu mettre de l'eau dans la chaudière et faire du feu sous celle-ci. D'abord le générateur en forme d'ellipsoïde de révolution ne possède que deux ouvertures, l'une à la partie supérieure pour conduire la vapeur à la machine, l'autre directement en dessous et au fond fermée par un bouchon à vis assez mal placé au plus vif du feu—si ce feu pouvait être vif. On ne pourrait donc introduire d'eau qu'en démontant le tuyau de vapeur. Cette opération, délicate avant l'allumage, serait impraticable en route pour refournir de l'eau à la chaudière à mesure de l'évaporation. D'autre part, la chaudière est entièrement entourée d'une enveloppe en tôle fermée de toutes parts, sauf en haut où il y a deux petites cheminées, et sur le côté où est une porte pour introduire le combustible; il n'y a ni grille ni place pour la mettre, le fond de l'enveloppe étant à 0·22 m. seulement en contre-bas du fond de la chaudière. Par où l'air destiné à la combustion pourrait-il s'introduire?

"Cette chaudière, telle qu'elle est actuellement et telle que la représentent les dessins du portefeuille, ne pourrait donc fonctionner en aucune manière, à moins qu'on ne suppose que le foyer agissait comme dans un samovar, et alors quelle production de vapeur pouvait-on espérer? Nous laissons de côté l'absence de soupape de sûreté et de tout moyen propre à faire connaître le niveau de l'eau dans la chaudière.

"Ce sont, quelque importants qu'ils soient, des détails bien secondaires en présence des imperfections radicales de ce générateur, qui nous semblent entraîner une impossibilité de fonctionnement. Il semblerait vraiment que la chaudière dont nous nous occupons, n'a jamais été achevée ou n'a pas été faite pour fonctionner; si on ajoute qu'elle reproduit tous les dèfauts qu'on avait signalés dans le générateur de la première voiture, on reconnaîtra qu'il y a là un mystère auquel nous n'avons jamais vu faire la moindre allusion dans tout ce qui a été écrit sur la machine de Gugnot, même par des ècrivains très éminents.

"Toute autre était la voiture de Trevithick qui a circulé en 1803 pendant plusieurs mois dans les rues de Londres en portant huit ou dix personnes, et en marchant à des vitesses de 8 kilomètres à l'heure qui pouvaient facilement être portées au double. Cette voiture était parfaitement pratique et, si elle n'a pas eu de succès durable, il ne faut pas en chercher la raison autre part que dans l'épuisement des ressources de l'auteur, epuisement qui l'obligea à chercher ailleurs un travail plus immédiatement rémunérateur. La mélancolique devise de Bernard Palissy, encore un inventeur méconnu, *pôvreté empeshe les bons esprits de parvenir*, a trouvé là une application de plus. La voiture de Trevithick n'eut pas la chance d'être conservée comme celle de Gugnot, elle fut vendue à la ferraille et le moteur fut utilisé pour actionner un laminoir à cintrer les cercles de roues chez un fabricant de voitures.

"Nous croyons équitable de partager entre Cugnot et Trevithick mais dans des proportions inégales, d'avoir été les pionniers de la locomotion mécanique sur les routes, l'un ayant fait le premier véhicule à vapeur qui ait existé, l'autre le premier qui ait fonctionné régulièrement et avec un plein succès sur des dispositions et pour un but d'ailleurs entièrement différents de ceux du précédent.

"Ces deux hommes ont, de plus, partagé le même destin, celui d'être méconnus de leur vivant et peu favorisés par la fortune mais encore dans des proportions très inégales. En effet, Gugnot dont les travaux avaient été encouragés et même payés par l'Etat, les vit dans ses dernières années récompensés par l'obtention d'une pension; son œuvre a été pieusement conservée, sa mémoire honorée presque de suite après sa mort et ses mérites célébrés, peut-être avec quelque exagération.

"Trevithick, au contraire, passa ses dernières années et mourut dans la misère, fut enterré à la charité et quelques ouvriers qui avaient travaillé à la construction de ses machines durent se cotiser et payer une garde nocturne pour préserver ses restes contre les voleurs de cadavres. Il s'était vu refuser dans ses derniers jours un secours national qu'il avait sollicité et cependant cet homme avait inventé, ou tout au moins avait réalise pratiquement la machine à haute pression, la locomotive routière, la locomotive de chemin de fer, la drague à vapeur, les caisses à eau métalliques pour la marine, les bouées, mâts et vergues en fer, etc., toutes choses dont les résultats ont plus tard été immenses."

Mallet.

THE LIGHT LOCOMOTIVE BILL.

Sir,—The Light Locomotive Bill which was recently introduced in the House of Lords is of such vital importance to the electrical industry that perhaps you will find space for the following:—Mr. Chaplin received the deputation headed by Sir David Salomons on the 12th February, after which I had an interview with him, and I wrote to him at length on the following day. I need not, however, trouble you with my letter of that date or Mr. Chaplin's courteous answer. When, however, on the 30th March we were able to obtain a copy of the Bill, I wrote to Mr. Chaplin a letter—copy of which I enclose, together with his reply. I am glad to be able to add that on Tuesday last Mr. Chaplin and Lord Harris did me the honour of receiving me at the Local Government Board. I found them most anxious to do all in their power to meet the reasonable requirements of all the industries interested in this particular Bill. They, however, are of opinion that it is essential some restriction should be placed on weight, as otherwise they fear that heavy traction engines will be run about the country and through our towns at a considerable speed. I am glad, however, to be able to add that though they were not able, until after consulting with their technical advisers, to determine the exact limit of weight that the Government may think necessary, yet I have no doubt when the Bill is read a second time in the House of Lords we shall find, instead of two tons, if not five, at any rate four tons will be substituted. Mr. Chaplin said that this is a matter of experiment, and that the Government, while most anxious to assist the industries connected therewith in every possible way, felt that until some experience was gained on the subject, they must be very cautious. Electrical omnibus traffic can certainly be conducted with success with a weight of five tons, and I have very little doubt that even if we are restricted to four tons, we shall be able to do very well with this traffic in our London streets and in other towns.

LOCOMOTIVES ON HIGHWAYS.

Sir,—I have the honour to remind you of the interview which you accorded me, after you had received the deputation on the above subject, on February 12th, together with my letter of February 13th and the answer of your secretary thereto. I am afraid that in the multitude of the business connected with your department, you have overlooked your kind promise to bear in mind my representation as to the vital importance to the electrical industry of not limiting the weight of the omnibuses or carriages to be used in towns to two tons. I may state that this limit, which is unfortunately contained in the Bill, has created great consternation amongst those connected with the electrical industry! It was only the day before yesterday that we were able to obtain a copy of the Bill, and I have already received communications from several of the leading representatives of electrical work, suggesting my writing to the papers, holding meetings, &c. I have, however, such confidence in your promise as to feel assured that such public agitation will not be necessary. If this limit is maintained, it will practically exclude the use of electricity for horseless omnibuses, though it is undoubtedly the safest, cleanest, and best for such carriages.

On Wednesday last I was speaking at the meeting of the Associated Chambers of Commerce as one of the Council of the London Chamber, and remembering your promise that you would bear in mind my representations on this subject, I stated that we might look forward to this Bill with complete confidence that there would be no restriction put on horseless omnibuses not found necessary with the existing omnibuses, and no unnecessary interference with the natural development of the electrical industry as applied to omnibuses, &c., in towns. Judging from the welcome this announcement received from the delegates of the Associated Chambers, I have no hesitation in saying that if it had entered into my mind that this prohibitory restriction of weight would have found place in the Bill, I should have been able to get a resolution passed unanimously asking you to withdraw your present limit, if, in fact, you thought it essential that there should be any limit whatever, or any restriction beyond that for street traffic in London at the present moment. You are aware that laden wagons of sixteen tons are now legally permitted to traverse our streets, while the large three-horse omnibuses, weighing very many tons, are allowed the free use of the Paris streets.

This question is one of such absolutely vital importance to the electrical industry, which, as you are aware, has been most seriously hampered in this country by what is now recognised as erroneous legislation, that I do hope you will be able to remember your most kind promise to give effect to my representations, and that you will prevent the agitation which must immediately be excited if this most lamentable, unnecessary, and unjust restriction is maintained in the Bill.

Naturally I will not ask you to see me with one or two other representatives of the industry during the short Easter holidays, but I shall be most glad if, before any public meeting is called, you would see me with one or two representatives of the electrical and carriage building industries, so that if possible the necessity for this agitation may be done away with.

I have the honour to remain, Sir,
Your obedient servant,
(Signed) S. Flood-Page.

To the Right Hon. H. Chaplin, M.P., &c. &c.

[Copy.]

Local Government Board, Whitehall, S.W.,
April 2nd, 1896.

Dear Sir,—Mr. Chaplin desires me to reply to your letter on the subject of the Light Locomotives Bill.

The Bill has been introduced in the House of Lords in consequence of the pressure of other business in the House of Commons.

The question of the weight of the articles to which the Bill is to apply is a matter of detail, and Mr. Chaplin is perfectly ready to receive and consider suggestions on the subject, which is a new one to all concerned, and of which there has been so little practical experience. He has forwarded your letter to Lord Harris, who has charge of the Bill in the House of Lords, and from whom your suggestions will, he is sure, receive every attention.

When the Easter holidays are over, Mr. Chaplin will be very willing to see you, in company with Lord Harris, or to receive in writing any further statement on the subject which you may like to submit.

Yours faithfully,
(Signed) H. C. Munro.

THE LIQUEFACTION OF GASES.

Sir,—After careful perusal of both "Zero's" letters, I am still unable to agree with him. With your permission I will explain why.

When oxygen escapes at high pressure through a narrow orifice situated in a tube of some length, two things happen: (1) production of cold, owing to conversion of sensible heat into mechanical energy of motion of the issuing gas; and (2) production of heat, from reconversion of the mechanical energy into sensible heat. (Parenthetically, I may point out to "Zero" that the issuing gas does do external work, because it does not flow into a vacuum, but is opposed at least by the pressure of the atmosphere.) As a matter of fact, proved by experiment and observation, these two things neutralise each other within a few inches from the orifice, and therefore the temperature of the gas becomes substantially what it was before expansion. But only substantially; accurately speaking, it is rather cooler than it was, which means, of course, that energy has disappeared somehow. But as "Zero" says, "After the air has left the cooler, there is no possibility of escape of heat or energy in any form" from the apparatus proper. What then has become of it? There is only one way out of the difficulty; the missing energy must have gone in doing internal work on the gas itself. It is obvious that, if all the heat of the gas before expansion were restored after expansion, there could be no progressive cooling effect, since the regenerative coils would all be bathed in gas no cooler than the compressed gas contained in them.

This disappearance of energy in internal work is, of course, the Thompson and Joule effect, of which "Zero" appears to hold so poor an opinion. But liberal as he is in unsupported assertions that it has nothing to do with the matter in hand, he is very sparing of arguments. His only one, indeed, is that it is too trifling in amount to be of any commercial value. That may well be so, but its commercial value is not under discussion. Of course, the Joule effect is trifling, but so is the efficiency of the self-intensive refrigerating process, an ounce or so of liquid oxygen being all there is to show for the energy absorbed by a big compressor during twenty or thirty minutes' work. As to a satisfactory explanation of the effect I do not know, but I believe that Lord Kelvin, so far from patching up a theory to suit it, predicted its existence from theoretical considerations before it was experimentally discovered.

I was not concerned in my former letter to discuss questions of priority. It was only as some sort of reply to "Zero's" strictures on the shortcomings of "dogmatic science" that I pointed out that Professor Dewar had actually constructed a machine, giving progressive cooling by the expansion of gas through a small orifice, before Dr. Hampson had done so, and before his patent was published. Although at the time I wrote I find I was in error in stating that Dr. Hampson's patent had not been granted, my argument was quite valid, since the specification had not then been published, and was not till last Saturday. But as "Zero" has indulged in some comparisons, may I suggest that it is rather an abuse of language to say that Professor Dewar's apparatus differs from Dr. Linde's *chiefly* in the use of frigorific agents? One might as well say that the chief difference between a boy's toy steamer and an ironclad is that in one methylated spirit, in the other coal, is the source of power. If "Zero," in accordance with his own excellent suggestion about looking up the recent literature of the subject, will consult No. 158 of the Chemical Society's "Proceedings," he will find an illustration of an apparatus which works without frigorific agents, and probably does not weigh as many ounces as Linde's does hundredweights. That seems to me a more important difference than the use of initial cooling, while a yet more important one is the employment of vacuum vessels as a protection against heat. Of the latter device, which I imagine was the outcome of dogmatic thermodynamic reasoning, I noticed that Dr. Hampson very wisely made use in his apparatus shown at Brin's Works.

April 22nd.

Cryos.

PERMANENT WAY.

Sir,—The correspondence on this subject will not be complete without a reference to the chairs. Since railways began these have not altered in any particular, except that they are heavier, being in all cases made of cast iron of the poorest quality.

It seems an extraordinary fact that in an age of steel a steel chair cannot be made commercially and mechanically to supersede the cast iron chair, the present cast iron chair being quite out of touch with other improvements in railway engineering. For example, many of the chairs weigh 56 lb. each—that is, 56 lb. of cast iron to support every 80 lb. or 90 lb. of steel rail. This is surely an enormous waste of material. It is not as if the weight of the chair were any advantage; quite the reverse. There would be less shock if there were no chair, or if the chair were made lighter and of stronger material, such as steel, which has the requisite properties for this purpose. The relative strength of the two metals being, say, 5 to 1, the steel chair might with safety be reduced to 20 lb. or even less, and still have ample margin for safety.

We platelayers experience daily the fact that when a vehicle leaves the rails, every cast iron chair that is touched by the tire flange is broken. This could not happen were the chairs made of similar material to that of the rails. It must not be forgotten that until broken chairs are replaced, traffic is suspended on the line. This causes much delay and trouble, and is noticeable every day where there is a lot of shunting, and where heavy mineral traffic is passed.

It seems a very curious thing that up till now a steel chair of sufficient merit has not yet been introduced. With our still increasing speeds and weights, its merits would be all the more appreciated. Railways were started with cast iron rails. What would we think of cast iron rails to-day?

April 20th.

For the Platelayers.

Sir,—The interest that is now being directed to this subject by engineers is in itself an evidence of its importance. There is a new element in the question, which is likely to have an important bearing on the subject; I refer to a steel chair that is being laid down on some of the Northern and Scotch lines. The trials, which are of course of too short a time to arrive at a definite conclusion, have so far proved that it is vastly stronger than the old chair, having been submitted to some very rough work in the yards of several of the Lanarkshire steel works, where the derailing of wagons with heavy loads is an almost every-day occurrence.

One thing is clearly demonstrated, that the derailing of a train does not affect the steel chairs further than a slight indent on the base, where they are struck by the passing tire flange. The maker, a Glasgow firm, claims a deal for them; but time alone will soon disclose what, if any other merit beyond cheapness and strength, they may possess.

James Andrew.

Glasgow, April 19th

LOCOMOTIVE FIRE-BOXES.

Sir,—Referring to the letter from "Adriatic" on the above subject in your last issue, it is generally considered that direct stays for the crown of the fire-box are less than useless, owing to the fact that since the inner and outer fire-box shells are both attached to the fire-box ring at the bottom of the water space, the expansion due to the heat will be, in the case of the inner fire-box, in an upward direction, and as copper is frequently used for this portion of the fire-box, and as its coefficient of expansion is greater than that of iron or steel, the crown of the inner fire-box shell will approach to the upper part of the boiler; also the direct stays will expand and thereby cause a depression of the inner fire-box crown. Now, when crown or bar stays are used, since they support the flat surface of the inner fire-box crown and act independently of the upper part of the boiler in contradistinction to direct stays, they will not be affected by the expansion due to heat of the inner fire-box. It is also for this reason that sling stays are said not to be of much, if any, use. Even when steel fire-boxes are adopted the above action takes place to more or less extent, since the inner fire-box shell, being nearest to the source of heat, expands more than the outer shell, which is separated by the layer of water in the water space.

I agree with your correspondent with regard to the Belpaire type of fire-box, and do not see any advantage that it possesses over the ordinary type.

Edward J. M. Davies.

24, Harrington-square, London, N.W., April 18th.

THE JENNY LIND.

Sir,—A curious story has been circulated to the effect that the Jenny Lind locomotive was designed as the result of the heating of an outside axle-box. The driving wheels of a certain engine had inside and outside bearings. On one run one of the outer bearings heated, the journal was wrenched off, and the engine proceeded with her inside bearing only; thereupon the outside bearings were dispensed with, and behold the Jenny Lind.

The story is preposterous, and it has not the merit of being new. If your readers will turn to the "Life of Trevithick," published in 1872, they will find a somewhat similar story told of an engine running between Carlisle and Preston. In this case it was a leading axle, and there was not a smash, because "a small roundish knot, projecting from the end of the axle in the wheel boss, alone retained it in its place, while the torn-off bearing was embedded as a solid mass with the fused brass and iron of the axle-box."

I do not pretend to know who designed the Jenny Lind. I fancy the first idea of it was to be found in an engine by Gray on the Brighton line, but I feel quite confident that there is not a trace of truth in the broken axle story, which seems to have been taken without acknowledgment from Trevithick's work, vol. i., page 219.

There are multitudes of very incredible stories told about locomotives, such as that about the 6ft. driving tire left in the ditch at Tring, the driver knowing nothing about it till he got to Chalk Farm. A collection of them would be interesting; perhaps some of your readers will contribute one or two. This about the Jenny Lind may be taken as a sample.

L. and S. W.

St. Deny's, April 21st.

THE CRYSTAL PALACE.

Sir,—I am glad to see that you admit to your correspondence columns a discussion concerning the best way to get into the Palace. I have reason to think that the directors are not blind to the truth and if I am not mistaken, they have entertained proposals from more than one contractor, but negotiations have fallen through.

The problem is not easy of solution, unless the æsthetic is to be sacrificed. A line such as that suggested by your correspondent "Norwood" would be very ugly, unless a considerable sum was spent in ornamental screens. I am rather disposed to think that the construction of an iron viaduct, in strict keeping with the architecture of the Palace, extending from the present Low Level entrance and curving round at the west water tower, would be the best solution. No railway or vehicle would be used. Powerful lifts of the kind used for the electric railway at King William-street would be employed to raise visitors to the entrance end of the viaduct. As the dimensions of this last need not be great, it would not be expensive. I do not know the difference in levels precisely, but I fancy it is about 50ft.

Dulwich, April 20th. M. E.

SIR,—Referring to "Norwood's" letter in THE ENGINEER of the 17th inst., I can, from personal experience, confirm all he says as to the difficulty of getting from the Low Level Station into the Crystal Palace. The remedy for this which I adopt, is to take the train from West Norwood Station to Gipsy Hill Station, and walk thence to the High Level Station. The walk is a pleasant one, on good footpaths all the way, and the distance traversed rather less than that entailed by walking up the many long passages and staircases from the Low Level Station. Others of my family do the same, and we save thereby time, money, and fatigue. I cannot understand the short-sightedness of the Crystal Palace directors in not providing some better mode of access than the existing one into the Palace from the Low Level Station.

London, April 18th. WEST NORWOOD, *ætat* 76.

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—I beg leave to correct the statement made by "Old Tubulous" in your issue of last week regarding the behaviour of the models shown by Professor Watkinson at the Institution of Naval Architects. Being present all the time the models were working, both before and during the meeting, I noticed that out of the five models which were working, only in two of them did the tubes fracture. I also noticed that one of the models—that of the Babcock—was working continuously for about four hours without any of the tubes being fractured. OBSERVER.

April 22nd.

THE INSTITUTION OF CIVIL ENGINEERS.

THE THIRLMERE WORKS FOR THE WATER SUPPLY OF MANCHESTER.

AT the ordinary meeting on Tuesday, the 14th April, Sir Benjamin Baker, K.C.M.G., the president, in the chair, two communications, dealing respectively with the water supply of Manchester and Liverpool, were read.

In the first paper, on "The Thirlmere Works for the Water Supply of Manchester," by Mr. G H. Hill, M. Inst. C.E., the Longdendale system of works, which, before the introduction of Thirlmere water, alone supplied the city, was first briefly described. The drainage area of Lake Thirlmere, the new source of supply, was 7400 acres, but the scheme included the taking of water from an additional area of 3600 acres. The geological formation was the lower silurian, and the water was remarkably clear, even in times of heavy flood. The mountains surrounding the lake were very precipitous, and the floods consequently very large. The rainfall varied between 100in. and 137in. in wet years, and between 60in. and 80in. in dry years; and the quantity of water available for the city, after giving 5½ million gallons per day as compensation to the river, was estimated at about 50 million gallons per day. The area of the lake in its natural condition was 328¼ acres, and when raised by the dam it would be 793 acres. The capacity of the reservoir then formed was more than 8000 million gallons, exclusive of the water below the surface of the original lake, which was not available.

The water in the lake was impounded by a masonry dam, the foundations of which were carried well into the rock, the maximum depth being 50ft. below the bed of the river. It was constructed of concrete, in which large masses of rock were imbedded, faced with heavy rock-faced masonry; and, to comply with the Act of Parliament, a public roadway had been made along the top. The discharge tunnel for carrying off surplus and compensation water was driven through the small isolated hill which rose on the centre-line of the dam. Upon it was sunk a shaft, in which the valves for controlling the water in the pipes laid in the tunnel were placed. The waste weir was constructed in the solid rock at one end of, and separate from, the dam; and a gauge basin, in which the compensation water could be measured, was provided. New roads, 7½ miles long, had been constructed round the lake.

The aqueduct to Manchester was 96 miles long, 14 miles of which was in tunnel, 37 miles in cut-and-over, and 45 miles in iron piping. It started at a circular straining well, lined with concrete and 40ft. in diameter, into which the water was admitted from the lake through a tunnel about 100 yards long. Upon this tunnel and adjoining the straining well was sunk a rectangular shaft lined with concrete in which the valves controlling the supply were placed. A hydraulic crane was provided for lifting the strainers in the straining well for washing, the valves were also worked by hydraulic power. The water after leaving the straining well entered the Dunmail Raise tunnel, 5188 yards in length. Some of the other long tunnels were the Moor Howe, 3040 yards; Nab Scar, 1419 yards; and the Skelgill, 1243 yards. Machinery worked by compressed air was largely used for driving the tunnels, which were lined with concrete sides and arching only where the nature of the ground required it, but the concrete invert was continuous throughout. Its internal width was 7ft. 1in., and the height 7ft.

The cut-and-cover portion of the aqueduct was constructed of concrete, the internal dimensions being the same as in the case of the tunnels. Manholes and ventilators were provided every quarter of a mile. The bridges were in all cases of masonry, and provision was made for emptying the aqueduct at convenient points. Throughout the tunnels and cut-and-cover the inclination was 20in. per mile.

Wherever the hydraulic gradient was intersected by valleys too deep to be crossed by bridges, five parallel lines of cast iron pipes were used, 40in. in diameter. As a first instalment of ten million gallons per day was at present only required by the city, only one of these pipes had been laid. They began, in the case of each syphon, in a rectangalar chamber, into which the concrete aqueduct discharged, and in which an automatic arrangement was placed at the mouth of each pipe to shut off the water from it in case of a burst. The total weight of one line of pipes, 45 miles long, was about 52,000 tons. The greatest care was taken in the manufacture, coating, testing, and handling of the pipes, each of which had a number cast on it, which was recorded, together with the tests applied, the dates, ultimate position on the aqueduct, and the name of the workman who made the joint. For turning angles, double-socketed bevel castings were used, about 12in. in length, and varying between 1 deg. and 10 deg. For larger angles a combination of these bevels was used, a spigot pipe 3ft. long being placed between each pair of bevels. All joints were run solid with lead, which was prevented from running into the pipe by a spring ring. The section of the lead was wedge-shaped, to avoid blown joints. The longest syphon, that crossing the valley of the Ribble, was 9½ miles in length, the greatest head of water being 427ft. at the crossing of the River Lune. At these crossings the pipes were carried by three 70ft. arches, each formed of cast iron ribs.

The number of valves on the 45 miles of piping was very large, and included stop valves and air valves, besides a large number of discharge valves, for emptying the pipes at convenient places. The self-acting valves had fulfilled their purpose perfectly in the case of the few bursts which had occurred, the water being completely shut off. The mechanism was set in motion by the increased energy of the water due to its greater velocity in the event of a burst: a pair of heavy weights was thus released, and closed a disc valve in the main, the operation being controlled and regulated by a cataract cylinder. An air vessel was provided to obviate shocks which might occur during the stoppage of the column of water; means were also provided for charging the air vessel. All stop valves, self-acting valves, and reflux valves were anchored, the latter in one direction only. Valve houses had been built over the large stop valves and self-acting valves, of sufficient size to cover the five lines of pipes; the roofs were of glass fixed in wrought iron framing; girders were fixed capable of carrying blocks and tackle for raising any part of the valves requiring repair.

The aqueduct delivered into a service reservoir at Prestwich, near Manchester, where a straining well was provided with lifting and washing arrangements.

The works had been let in nine and the ironwork in eighteen contracts. Portland cement concrete had been used throughout, the quantity being about 100,000 tons. The total cost of the works to the date of the opening was about £2,800,000, including Parliamentary expenses, which were exceptionally large. The complete scheme would cost about £4,400,000.

THE VYRNWY WORKS FOR THE WATER SUPPLY OF LIVERPOOL.

The second paper was entitled "The Vyrnwy Works for the Water Supply of Liverpool," by Mr. G. F. Deacon, M. Inst. C.E. The Vyrnwy reservoir, now known as Lake Vyrnwy, occupied the site of a post-glacial lake, which had been filled chiefly with alluvial detritus to a height of about 45ft. above the original water level. That level was maintained by a bar of rock at a narrow part of the valley such as was found in most glacial lake basins. On removal of the dislocated or otherwise unsound rock in this bar, a sound foundation was met with about 15ft. lower, so that the deepest part of the foundation was nearly 60ft. below the ground level; the height of the dam to the sill level being 84ft. above the river, and the water level above the lowest part of the foundation 144ft.

Below the sill of the dam and above the outlet to the aqueduct, Lake Vyrnwy contained 12,131 million gallons. Its area was 1121 acres, only reduced to 1036 acres 10ft. lower. An average cross-section did not differ widely from a figure with a horizontal base 2000ft. wide, having a depth of water over it of 70ft., and end slopes of 2½ to 1.

The author drew special attention to the methods adopted for securing water-tightness, and showed by the results obtained from this structure and from a concrete culvert—the walls of which were only 18in. thick—subject to a vertical pressure of water of 56ft., that concrete might be made perfectly water-tight by avoiding the use of so much water as to render it incompressible when first placed *in situ*, and by ramming it until the jelly-like condition indicative of incompressibility was obtained.

Thirty-three per cent. of the stones used in the dam weighed between four tons and ten tons each. The hearting-stones were roughly dressed on their beds, but were otherwise left quite rough. The face stones had rectangular faces, and no part of any stone was allowed to come within 1in. of any other stone. The stones and rock were rendered scrupulously clean with wire brushes and jets of water under pressure. The foundation rock was drained, except within about 15ft. of the face, by numerous funnels carried up to above the back-water level, and the total leakage from the central 8000 square yards of rock foundation, including that through the dam, if any, amounted to about two gallons a minute. The specific gravity of the rock of which the dam was built was 2·721, or 170 lb. per cubic foot; that of the concrete, when dry, averaged about 2·51, or about 156 lb. per cubic foot, and that of the whole dam was 2·595, or about 162 lb. per cubic foot, a figure ascertained by comparing the measured volume of the work with the total weight of the materials put into it, all of which were carefully weighed. Crushed rock was largely used in the preparation of the mortar.

The mode of securing water-tightness of the two culverts, 15ft. in diameter, through the dam was explained. The compensation water to the Vyrnwy and the Severn, of which it was a tributary, was 10 million gallons a day, and 40 million gallons a day in addition, during four successive days in each of the eight months from February to October inclusive. The modes of gauging were also set forth.

The aqueduct commenced at a valve-tower standing in the deep water of the lake, provided with strainers of copper wire gauze, which were removed, washed, and replaced wholly by hydraulic machinery. The outlet valves consisted of a series of short cylinders standing upon one another so as to form a vertical pipe, and the joint between any pair of such cylinders was capable of being opened very readily by hydraulic pressure. Thus the water was drawn off at any level desired. The aqueduct was constructed for the passage of 40 million gallons per day or more, with the exception of the iron syphon pipes and some other portions not required until later, and every part of the work now constructed would pass the full amount of between 13 million and 15 million gallons a day required as the first instalment of water. The gradient of the aqueduct being from 4·5ft. to 6·87ft. per mile, cast iron pipes under pressure had been used, except in the three tunnels constructed at the hydraulic gradient, and in certain special places where steel had been employed. Throughout the syphons the hydraulic gradient had been varied wherever it was economical to vary it, subject to the total loss of head amounting to whatever could be afforded in each case. All specially expensive parts, such as valves and pipes under heavy pressure or in tunnels, had been considerably reduced in diameter from that of the cheaper portions.

The filter-beds were at Oswestry, where a recording gauge gave full information as to the variations in the water passing through the aqueduct from time to time. The five balancing reservoirs on the aqueduct were generally described, and the Norton tank, where the balancing reservoir was at a height of 113ft. above Norton Hill, was particularly referred to. The tank contained about 650,000 gallons, and consisted mainly of a steel basin in the form of the segment of a sphere in tension, depending from a steel ring in compression, resting through the medium of an expansion ring, upon the masonry.

The six river crossings, thirteen railway crossings, and six canal crossings, including the Weaver Navigation and the Manchester Ship Canal, were generally described. The crossing under the river Mersey was the most difficult portion met with. The pipes had been originally intended to pass through the bed of the river, but Parliamentary exigencies rendered it necessary to submit to a reference clause which resulted in a tunnel having to be constructed through ground full of water under a head of 51ft. The work was, however, successfully performed by means of a shield, and was now in every respect satisfactory.

AMERICAN PATENTS RECORDS.—The U.S. Patent-office has issued 3075 patents for inventions, contrivances, and discoveries in telegraphy. Over 25,000 inventions for the manipulation of metals have been patented. There are 636 patented fuels or methods of preparing wood, coal, and coke for use. Over 16,000 patents have been issued for the various kinds of electrical appliances. There are 1771 patents on the mechanism employed in sinking artesian or oil wells. Railways and railway appliances are represented by 8334 models. The annealing and tempering of metals have called for much attention, no less than 736 devices for these purposes having been patented. There are 4240 models of patented pumps in the Washington office,

TRACTION ENGINES ON ROADS.

THE Select Committee of the House of Commons appointed to investigate the working of the laws relating to the above subject sat again for the first time since the Easter vacation on Thursday, the 16th inst. The first witness called to give evidence was Mr. F. Bacon Frank, vice-chairman of the West Riding of Yorkshire County Council, and chairman of the Rural District Council. Mr. Frank stated that there were forty-nine traction engines licensed in the West Riding, the revenue derived from which was £450 annually, which amount he did not consider was sufficient to compensate for the damage done to the roads. He complained that Clause 23 of the Highways and Locomotives (Amendment) Act of 1878 was not clear enough, and, in consequence, did not work satisfactorily.

Mr. Trevor Edwards, the solicitor to the West Riding County Council, the next witness, considered that the maximum limit of speed might be increased in towns and villages from two to three miles an hour, but that on the country roads should be maintained at the present limit, viz., four miles. Asked regarding the number of men employed on each engine, the witness gave it as his opinion that the present number—three—was not too many. He recommended that the drivers, as well as the engines, should be licensed—a course he considered necessary for public safety. This licensing he would place in the hands of the county authorities, which bodies ought also to be allowed, as at present, to make bye-laws restricting the hours of operation of the engines. Other recommendations made by the witness were that no more than three wagons should be hauled by one locomotive, and the total length of such train, including engines, be not more than 54ft.; that in addition to the two lights carried on the front of the engine at nights, there should also be a red light carried at the rear; and that the clause relating to extraordinary traffic should be amended.

Mr. Hulton, Chairman of the Main Roads and Bridges Committee of the Lancashire County Council, having charge of 683 miles of main road and 834 miles of "secondary" roads, at an annual cost of £137,000 and £25,000 respectively, stated that the annual cost per mile of these roads varied between £20 and £600, according to the district. The cost of a licence taken out within the jurisdiction of this Authority was stated to be £5, while engines licensed by neighbouring counties could have their licences endorsed for a nominal fee of 10s. 6d. Mr. Hulton endorsed the recommendation of the previous witness regarding the increase of the maximum limit of speed in towns and villages, but considered that the working of Clause 23 of the 1878 Act was satisfactory. He did not think that uniformity of prohibited hours could be achieved, since the conditions necessary for working in different counties and county boroughs were so dissimilar. He recommended the legalising of the Bolton block tires, which had given great satisfaction in Lancashire.

Mr. J. Vickers Edwards, the surveyor to the West Riding of Yorkhire County Council, next gave evidence, in which he stated that their roads were of a condition quite suitable for ordinary horse traffic, but not strong enough for locomotives. He approved of the principle of the Bolton block wheel, but considered it very liable to get out of order, and consequently inflict much damage to the road surface.

At the proceedings of the Committee on Monday, the 20th inst., Mr. J. Moncur, surveyor of main roads, Staffordshire; Mr. Thomas, A.M. Inst. C.E., county surveyor, Buckinghamshire; and Mr. Phillips, county surveyor, Gloucestershire, were the witnesses examined. Mr. Moncur said there were a large number of locomotives at work in Staffordshire, and the prohibited hours of working were during the early part of the night. He would not advocate the increase of the maximum limit of speed, but would place the choice of type of wheels in the power of the Local Government Board. He would limit the use of traction engines to roads 18ft. and upwards in width, and thought it advisable to restrict the net loads hauled by engines up gradients of 1 in 10 to five tons. The other chief recommendations of witnesses were: that no more than three trucks should be allowed to be hauled by one engine, and that a red light be carried in the rear at nights. Mr. Thomas stated that there were forty engines licensed in Bucks, the licence fee being £3, and that there were no prohibited hours for working. He would increase the maximum limit of speed on country roads to six miles, but recommended no addition to the speed in towns and villages. His experience of the construction of wagon wheels showed that the tires were frequently too narrow, and suggested that they should have a clear inch in width for each ton carried. As regards the extraordinary traffic clause, he had no complaint to make, but thought that, with the increase of speeds indicated, the man in front of the engines might be provided with a cycle.

The last witness, Mr. Phillips, informed the Committee that there were no prohibited hours for working in Gloucestershire, and that no accidents had resulted from this arrangement. The licence fees varied from £10 per annum for engines of 10 tons and upwards, decreasing £1 per ton below this weight. Mr. Phillips recommended the alteration of the clause which specified that all wheels should be cylindrical; the registration of all road engines, including rollers and agricultural engines, and the insistence of the inspection of engines by the registration authorities. In place of the annual licence the witness proposed a novel scheme for levying a tonnage rate on the net loads hauled, and suggested as a reasonable rate ¼d. per ton per mile. This would necessitate the forming of small sub-committees of County Councils, and the detective duties might be performed by the weights and measures authorities. He stated that by this arrangement about £700 per annum would be derived from the traffic in Gloucestershire, as against about £180 as at present with licence fees, and that owners had expressed themselves satisfied with the scheme, provided that the extraordinary traffic clause were abandoned. The witness stated that to raise the quality of the Gloucestershire roads, which had not yet been so treated, up to locomotive standard, would involve the expenditure of about £500 per mile, or £250,000 altogether, a sum which he did not consider ought to come out of the pockets of ratepayers.

The Committee again adjourned until yesterday—Thursday.

STEPS have recently been taken to increase the water supply of Slough, for which purpose the engineer, Mr. Secker, has had a series of three 11½in. artesian tube wells bored by Messrs. Le Grand and Sutcliff, of London, to an average depth of 150ft., the chalk formation being reached at from 61ft. to 72ft. below surface. The boring operations occupied ten weeks, or an average of twenty days each, including pumping trials. The three wells are to be coupled to one receiving main, and their united yield is equal to a supply of nearly two million gallons per diem.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies*

C. W. R.—*We stated a fact concerning water-tight doors. We did not express an opinion. The Admiralty will not adopt doors of the kind you suggest because they would take up too much room. Drawings and models of doors of the kind were shown and explained at the last meeting of the Institution of Naval Architects, and they were absolutely ignored by everyone present. We hold that the air lock idea is excellent, but we can also say at the same time that there are many objections to it. If, however, you can send a drawing properly worked out to show how your doors would be fitted, we will publish it.*

BOOKS ON RAILWAY SIGNALS.

(*To the Editor of The Engineer.*)

SIR,—Would any reader be kind enough to inform me if there is any work or works published which would give me full information of the working of railway signals in all countries, also of fog signals; also where I could get these works? J. B. P.

London, April 15th.

REVERSING PROPELLERS.

(*To the Editor of The Engineer.*)

SIR,—Will any reader kindly let me know the name and address of the makers of reversible propellers? J. W. B.

April 21st.

DR. ANGUS SMITH'S COMPOSITION FOR COATING WATER PIPES.

(*To the Editor of The Engineer.*)

SIR,—Will any reader tell what are the materials used in this composition, or where I can find a description of it? C. H. B.

London, April 21st.

SUPERHEATING STEAM.

(*To the Editor of The Engineer.*)

SIR,—I have a horizontal brick flue, 2ft. by 2ft. by 27ft., through which furnace gases are continuously passing, temperature 700 deg. to 1000 deg. I wish to utilise a portion of this heat, to superheat steam for boiling down waste liquors, &c. Would any of your readers advise me how best to do this? SUBSCRIBER.

April 21st.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, April 30th, at 8 p.m. Paper: "On Railway Telegraphs, with Special Reference to Recent Improvements," by W. Langdon, member.

GEOLOGISTS' ASSOCIATION.—Friday, May 1st, at 8 p.m. Papers: "On the Physical Geology of Purbeck," by A. Strahan, F.G.S., illustrated by the lantern. "Notes on Mollusca from the Skiddaw Slates," by J. Postlethwaite, F.G.S.

SOCIETY OF ARTS.—Monday, April 27th, at 8 p.m. Cantor Lectures: "Applied Electro Chemistry," by James Swinburne. Four Lectures. Lecture I.—Introductory—Phenomena of Electrolysis. Wednesday, April 29th, at 8 p.m. Paper: "Fruit Drying or Evaporation," by Edward W. Badger.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, April 28th. Afternoon Lectures, at 3 p.m.: "Child Study and Education," by Professor James Sully, M.A., LL.D. (Lecture III.) Thursday, April 30th. "Recent Chemical Progress," by Professor Dewar, M.A., LL.D., F.R.S., M.R.I. (Lecture III.) Friday, May 1st, at 9 p.m. Paper: "Chronographs and their Application to Gun Ballistics," by Colonel H. Watkin, C.B., R.A., M.R.I.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Saturday, April 25th, at 6 p.m. Discussion on "Some Structural Details of Modern Ships," by Mr. M. C. James, will be resumed. Discussion on "The Determination of the Forces which produce Vibration with Three-crank Engines at High Speeds," by Mr. R. M. Ferrier, and "Balancing High Speed Engines," by Mr. A. E. Doxford, will be opened by Mr. James Patterson.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS.—Saturday, April 25th, at 2 p.m. Papers for discussion: "Short History of the Jameson Coke Oven," by Mr. John Jameson. "Report of the Proceedings of the Flameless Explosives Committee," by Mr. A. C. Kayll, engineer. "Resistance of Air Currents in Mines," by Mr. T. L. Elwen. "Coal-cutting by Machinery," by Mr. William Blakemore. "A Compound Winding Engine," by Prof. W. Galloway. Paper: "Gas Producers and Gaseous Fuel Illuminants," by Mr. Robert Martin.

THE INSTITUTION OF CIVIL ENGINEERS.—Tuesday, April 28th, at 8 p.m. Papers to be discussed: "The Thirlmere Works for the Water Supply of Manchester," by Mr. G. H. Hill, M. Inst. C.E. "The Vyrnwy Works for the Water Supply of Liverpool," by Mr. G. F. Deacon, M. Inst. C.E. Papers to be read: "American and British Methods of Manufacturing Steel Plate," by Mr. Jeremiah Head, M. Inst. C.E. "Four American Rolling Mills, by Mr. Samuel T. Wellman. Friday, May 1st, at 8 p.m. Students' meeting—Paper: "Swing Bridge over the River Nene at Sutton Bridge," by Mr. Edward S. McDonald, Stud. Inst. C.E. Sir Douglas Fox, Vice-president, Inst. C.E., will preside.

THE ENGINEER.

APRIL 24, 1896.

HORSELESS CARRIAGES.

IT is absurd to doubt that a great and novel industry is springing up in this country. The self-propelled vehicle is with us, and its popularity will not be less than that of the bicycle. The history of the movement in favour of mechanical road carriages has yet to be written. History is being made daily. But our descendants will probably wonder not that the horseless carriage has caught the public fancy, satisfied an all but universal want, or gratified a ubiquitous desire, but that we, as a nation, consented for so many years to leave the finest highways in the world comparatively unutilised. No doubt the bicycle has done much to educate public opinion. We have learned that the roads of a country can be employed without the aid of horses and without walking on them. The fact was known to comparatively few until recently. Now it is understood by everyone. The step from the bicycle to the horseless carriage is as nothing to the leap between the horse drawn vehicle and the bicycle. It is impossible to forecast the results of the adoption of the new mode of locomotion with either certainty or profit. But it is not difficult to understand why the horseless carriage should be popular. The age is an age of movement. A little thought will serve to convince most men that the great difference between the world of to-day and the world at the beginning of the present century is that locomotion of every kind, and in all its endless forms, is infinitely more facile and more abundant now than then. Civilisation and locomotion go together. Not locomotion of the individual or the thing only, but locomotion of thought. It is because he has given the world roads and railways, and steamships and telegraphs, that the engineer has been the civiliser of the world. He has done more to promote material progress than the warrior, the statesman, or the philosopher. And the desire for locomotion has grown, and is growing. More people travel each day than travelled the day before. Our ships steam faster, our trains run more quickly, year after year. The horseless carriage will come to satisfy the wants of a humanity which finds the railway too unwieldy, the horse too expensive, and the cycle too trivial.

Very largely, no doubt, the advent of the oil engine has promoted the growth of the horseless carriage. Legislation has laid a heavy hand on steam, and has done infinite harm not only by prohibiting the use of steam-propelled pleasure carriages, but by stopping invention and the development of ideas. Inventors and engineers have been assured so strongly by legal enactments that a steam-propelled vehicle must be a nuisance that they have come to believe it. The petroleum motor has not yet earned or received a pestilent parliamentary reputation. The public are willing to believe in it, though they will not believe in steam, knowing the while not much, if anything, about either; and less in any case about steam than about petroleum. We are much mistaken, however, if it is not yet found that steam will hold its own against the petroleum motor. Its possibilities are far greater now than they ever have been hitherto. We can produce engines of a lightness undreamed of in the days of Hancock or Gurney, and boilers which, fired with petroleum, will realise the wildest dream of the inventor in the matter of small size and power. A copper coil which can be carried on a man's forearm will, as we have seen, make steam enough to propel a carriage carrying four persons on an indifferent road at a good pace. But it is indisputable, whatever steam may be or may do, that the notion of the petroleum motor has proved attractive; and our friends in France have not hesitated to push praise of the light oil engine to the extreme limits of veracity. The public has been promised a vehicle which will leave nothing to be desired, and the public has wondered how it has done without that vehicle so long. That is one reason why the present movement is so powerful, so widespread, and so rapid. But this is not all; the public needs to be educated, and we think we are justified in taking credit to ourselves for the part we have played in promoting the establishment of the new industry.

For years we have carefully placed before our readers particulars of every advance that was made in steam locomotion on common roads. We have persistently advocated the cause of the traction engine and the modification of legislative restriction. When in France, where the law of highways does not kill invention in the matter of locomotion, the new vehicle propelled by oil was brought before the public, we despatched a special commissioner to examine, investigate, and describe for the benefit of our readers; and we venture to say that THE ENGINEER was the first journal in England to tell the world what was being done in France. So impressed were we with the results of our investigation, that we decided to do all that lay in our power to promote the construction and use in Great Britain, and in British possessions, of the self-propelled vehicle. To that end we took two steps of prime importance. To stimulate invention we offered substantial money prizes, and we were successful in enlisting the warm co-operation of two eminent engineers and one equally eminent electrician. The names of Sir Frederick Bramwell, Mr. J. Audley Aspinall, and Dr. Hopkinson, are a sufficient guarantee, not only of the trustworthiness of the trials which will decide the awarding of our prizes, but of the real importance of the undertaking as a whole. We cannot but think that the possession of a first prize may be taken as a certificate of merit, possessing an unparalleled significance. The severe nature of the tests to which the competing vehicles will be submitted, and the absolute competence of the judges to estimate at their true value each phase of the performance of the vehicles, will impart maximum value to the awards, a value which we feel certain the public will not fail to appreciate.

But it was not enough to promote the construction or development of the horseless carriage. It was essential that our highways should be thrown open to its use. To this end we promoted a memorial to the Government, and the host of signatures we have obtained in every centre of industry in the kingdom could not fail to impress Government, and assist the good work. The mere demand for change in the law could effect little unless it was backed up by substantial evidence of the soundness of the demand and the extended range of the desire for a change. We have left nothing undone to supply this evidence, and our efforts have been, we are glad to say, completely successful. The passing of Lord Harris's Bill is, we venture to hope, now a mere question of time, and long before the date of our trials the highways will be thrown open to the use of the self-propelled carriage, under the same restrictions as those which now regulate the use of the horse-drawn vehicle. We ask for no more, and the country will be satisfied with no less. At every turn we hear of exhibitions, competitions, and prizes. They will all do good, no doubt. Far be it from us to say that they will not. But in the midst of the hurry and dust, and confusion of tongues, it is possible that the fact that to THE ENGINEER, the inception of the whole movement in this country is mainly, if not wholly, due may be forgotten; and we have been too much gratified by the success which has hitherto attended our efforts to suffer the truth to slip into oblivion. It is not every day that a journal can accomplish so much for the promotion of a new national industry as THE ENGINEER has done. That must be our sufficient excuse for insisting, as we do, on the fact.

ENGINEERS FOR THE ROYAL NAVY.

To state opinions as facts is a not unusual method of controversy. A notable example is supplied by a letter written by Mr. Albert Durston, Chief Engineer of the Navy, in reply to one addressed to him by Mr. Adamson, secretary of the Institute of Marine Engineers. In our last impression we referred at some length to a paper read by Mr. F. Cooper on "Engineers and the Royal Naval Reserve." We have not got a copy of Mr. Adamson's letter, which is of the less consequence that we can gather its tenour without difficulty from Mr. Durston's reply. That gentleman says:—"The paper on R. N. R. engineers is a most interesting one, and the matter is well put. Unfortunately, it is based on the erroneous statement published in THE ENGINEER, and it takes no account of our staff of chief engine-room artificers, and engine-room artificers who correspond to the junior engineer of the old navy or the mercantile marine. When these are taken into account our engine-room staffs compare favourably with the mercantile marine. As to points named in your letter (1) assistant-engineers for temporary service, as advertised for, the regulations will show we desire to get the pick of young mechanics whose parents have made some sacrifice for them. We do not, however, intend to increase them much more at present. (2) Engine-room artificers, as I have said, do junior engineers' duties, and I think their case well deserves consideration as to whether some of them could not have warrant officer's rank. (3) We should not, except in an emergency, draft engineers direct from the mercantile into the Royal Navy. (4) I think it would be a most desirable thing to put R. N. R. engineers on same footing as to training, &c., as the executive or deck officers."

The statement referred to as "erroneous" was published in our impression for March 7th last year. Whether it is erroneous or not is a matter of opinion, and not of fact, as Mr. Durston seems to think. Mr. Durston, it must be understood, speaks for the Admiralty, and what he has to say on the subject we may regard with strict propriety as an Admiralty utterance. We have stated, it will be remembered, that at least 1100 engineers and assistant-engineers are needed, and that a less number would not give the official complement to each warship that may be put in commission. We carefully eliminated all craft which no longer deserved the name of fighting ships; and we took for granted that if war on anything like a large scale broke out we should need all the ships we have. But the Admiralty, we have excellent reason to believe, do not contemplate the use of all our warships under any conceivable circumstances; and they have arrived at the conclusion that 850 engineer officers of all grades are sufficient to meet the needs of the Navy for the next twelve months. Now this may very well be true, and yet the statement which we have made, far from being erroneous, will remain strictly accurate. We assert, and we advance it as a fact, that there should be on the Admiralty lists a sufficient number of engineers to utilise every ship we possess, always and at all times. It appears to be useless to go on building more and more ships, while we cannot utilise what we have got. But it may very reasonably be argued, that this is a matter of opinion, and that none but experts can say how many ships of war we should need if war broke out. It happens that we have a very recent expression of opinion on this point from an expert, whose authority will scarcely be questioned. Lord Charles Beresford was the guest of the Sheffield and District Press Club on Saturday night, and among other interesting things he said:—"The First Lord of the Admiralty said we should not want all our ships. That he utterly denied. We were short of ships, and before we had been at sea a month we would wish we had more. *There ought to be a ship's company rating for every ship in the service, without touching the Reserves.* Between April, 1897, and 1899, we should have to get 22,000 men. Where was the First Lord going to get them? It was a very different matter getting men in these days, from what it was in former days. Now we require engine-room artificers, artificers, and stokers. These men were all skilled men. It took five years to make a seaman-gunner who could handle guns. In the Marlborough, the first ship in which he went to sea, 10 per cent. of those on board were non-combatants. In the Magnificent now there were 52 per cent. of non-combatants, so they could understand how the character of a ship's company had altered. The position of being short of actual requirements at the present moment, and not being ready for requirements three years ahead, was a dangerous position."

We direct attention to the words which we have italicised. As regards bluejackets, we do not express any opinion. We are content to take Lord Charles Beresford's word. But we do ourselves assert—and that as strongly as possible—that every ship in the service should have her full complement of engineers. Probably if Mr. Durston will look at the matter from this point of view he will see that far from The Engineer's statement being erroneous, it was perfectly accurate in the most minute particulars. The difference between ourselves and the Admiralty is not one concerning the number of engineers, but the number of ships. Provided all the ships in the Navy of the classes we particularised are to be available in war time, 1100 engineers must also be available to man them. Mr. Durston does not, we take it, dispute this. It cannot be disputed in the face of the Navy List. The contention of the Admiralty is that all the ships we possess would not be available in war time, whether we had engineers for them or not. This is a very remarkable and even startling proposition. We shall be surprised if we have heard the last of it.

It may be urged that this is not what the Admiralty really means. That they "back their luck" that there will be no war, and that, consequently, there are engineers in abundance. We fancy that very recent events must have excited some little doubt at Whitehall as to the prudence of this policy. It would in any case be interesting to know what percentage of our fleet our Admiralty contemplate putting in commission on emergency. We could then form some opinion as to whether there is or is not a delusion operating at Whitehall. But let us, for the sake of argument, conclude that only a percentage of our fleet would take part in a war, and go on to ask on what basis 850 officers are held to be sufficient. So far as we can gather, no provision whatever is made in this estimate for the "expenditure" of engineers. As we have already pointed out, they are, it appears, in Admiralty estimation endowed with charmed lives, which will carry them safe from violence, and with iron constitutions which will enable them to sustain the most tremendous bodily and mental exertions without breaking down. Our estimate of 1100 officers provides no reserve of any kind. There is nothing to draw on if a man is invalided; no one to take the place of a man killed or disabled. In a word, the error committed by The Engineer lies in under-estimating instead of over-estimating the number which should be available. We may knock off 30 per cent. of all the ships on our list, and then in war time 1100 would be all too few.

So much being said in defence of our accuracy, we may go on to consider the subject from another point of view. Lord Charles Beresford pointed out in the speech to which we have just referred, that the Admiralty are going to add forty-six ships to our fleet within the next two years. We shall be under rather than over the mark if we say that 100 engineers of various grades will be needed for these vessels. It is true that many of them are torpedo catchers with but one engineer each, but others ought not to carry less than six engineers each. Where, we ask, do the Admiralty propose to get these men? And we may ask further, why it is that the Admiralty is so persistent in its policy of under-manning the engine-rooms of our fleet? The money saved is such a small sum by comparison with other items of expenditure, that we cannot believe that parsimony or a desire to save has anything to do with the matter. Is it not a fact that we have not more naval engineers because the Admiralty cannot get them? On this point a little enlightenment is most desirable. The official statement that all the men wanted are to be had must be discounted. Everything depends on how many the Admiralty say are necessary. Instead of 850 officers, they may hold that 50 would suffice. They may think that all the men they can get, however few, are enough. On this point we want something more reassuring than a mere expression of Admiralty opinion. If we had an engineer as First Lord we fancy that matters would assume a somewhat different aspect.

We gather from Mr. Durston's letter that the Admiralty regard engine-room artificers as competent to discharge engineers' duties. Is it too much to suppose that the Admiralty rely on the artificers to supply the deficiency in officers? Mr. Durston's letter would appear to suggest that it is not. If so, the inconsistency of the policy of Whitehall becomes more than ever manifest. We are told that the naval engineer must have an exceptionally excellent technical education, and in the same breath we are informed that artificers are competent to discharge the duties that highly trained gentlemen are expected to perform. It really is time, we think, that the Admiralty should make some specific statement of the nature of its policy as regards engineer affairs; there is nothing more likely to lead to confusion and misapprehension than reticence. The First Lord of the Admiralty virtually ignores the engineering branch of the service in his speeches. Others are not more open. No good purpose is served by silence, and much would be gained by a definite explanation of the system to be adopted in future in manning the engine-rooms and stokeholds of our ships of war, and the reason why two engineers and half-a-dozen artificers can do the work in a man-of-war that cannot be performed by less than a dozen engineers, with their greasers, &c., in an Atlantic liner, and of the part which the artificer is intended to play in future. Several other matters suggest themselves as needing elucidation; we should be satisfied, however, with definite information on the points we have stated.

THE INCANDESCENT GAS LIGHT CASE.

Public interest has been aroused in no common degree by the actions which have lately been brought by the Incandescent Gas Light Company, Limited, against the De Mare Incandescent Gas Light System, Limited, and the Sunlight Incandescent Gas Lamp Company, Limited, for infringement of the former corporation's patent. Many technical cases of the greatest commercial importance, and directly affecting the convenience and pockets of thousands of the general public, are fought out in comparative obscurity, and receive brief paragraphic notice in the daily press. The only difference in the present instance consists in the fact that the matter in dispute is one coming immediately and literally before the eyes of the community. Throughout the country, in every little town boasting a small gas works, one or more enterprising tradesmen are certain to have adopted the novel light to dazzle their customers and display their goods, and both users and onlookers feel that they have some personal knowledge of the nature and qualities of the mode of illumination known succinctly but inexactly as the incandescent gas light. The state of general opinion is accurately indicated by the appearance in the *Times* of Monday last, not only of an account of the judgments given on Saturday, but also of a leading article recapitulating and commenting upon those judgments. A judicial delivery on a patented process for the production of synthetic indigo at a cost lower than that of the natural material might occur and pass almost unregarded, although its effect upon one of the great industries of the greatest of our dependencies might prove to be colossal. That the obvious is always to be met with is more than an etymological truism. But apart from its popular side, the recent contest possesses interest of a technical character sufficient to warrant its consideration in these columns.

For months it has been a matter of common knowledge that the Welsbach system of lighting, owned and worked by the Incandescent Gas Light Company, has, after a long period of probation, advanced to an assured industrial position. Difficulties and defects in the earlier forms of the light have been gradually overcome by the persevering research of the company's technical advisers, and a light has been produced which for economy and efficiency takes a high rank. With the remembrance of lean years the company, being a trading organisation, no doubt sought to recoup itself with all possible speed. The prices charged for burners and mantles bore but a distant relationship to their cost of production, and the public, legitimately enough, was made to pay pretty stiffly for a valuable idea. The natural result followed. Others were anxious to reap part of the rich harvest which it was evident could be gathered from the not wholly intelligible anxiety of civilised man for a superfluity of artificial light. The principle underlying all varieties of incandescent gas lighting has been dealt with in this journal within the last few weeks, and needs no re-statement now. It is enough to say that inventors seeking a method to rival the Welsbach light must devise a different form for the refractory material to be heated, or must employ a different refractory material, or must prove the Welsbach patent invalid. Attempts in all these directions have been made, but with indifferent success. In the defence offered by the De Mare Incandescent Gas Light System it was contended that the patent was not novel, as the production of light by heating certain refractory substances has long been known and practised. This was emphatically negatived by Mr. Justice Wills, who, in a judgment showing a remarkable grasp of a subject not without complexity, stated that, in his opinion, the patent covered perfectly new ground and had shown the road to success in a region where before was failure unrelieved. Further, it was argued for the defence that the specification did not give instructions sufficiently precise to allow of the manufacture of mantles by the prescription included therein; this was also overruled. Thus for the validity of the Welsbach patent there has been issued a weighty pronouncement. Beaten on this point, the defence resorted to the denial that their method of lighting infringed the Welsbach patent. The structure used by the De Mare Company is a "plume," described in the judgment as consisting "of a number of threads tied on to a platinium wire, and arranged so as to form a sort of fringe, all the threads of which are brought very closely together where they are strung on to the wire, but allowed to separate as they leave it, so that the apparatus looks like a housemaid's small brush, the cross-sections of which would take the shape of a fan." The refractory oxides used in the formation of this plume are zirconia, erbia, and magnesia, and in the opinion of the Court fall within the scope of the Welsbach specification. Differences in the mode of manufacture and in the design of the finished plume from those of the Welsbach mantle were held not to constitute a departure sufficiently great to exonerate the defendants from the charge of infringement. Judgment was accordingly given against the De Mare Company, and, should the decision be upheld on appeal, the manufacture of plumes of the refractory rare earths must be discontinued until the lapse of the Welsbach patent.

The second case—that against the Sunlight Company—took a somewhat different course, and led to a wholly different conclusion. The refractory structure manufactured by the Sunlight Company is a hood or mantle scarcely distinguishable in form from that made by the Incandescent Gas Light Company. The material of which it consists, however, is composed of 50-60 per cent. of alumina, about 30 per cent. of zirconia, and a top-dressing of chromic oxide. The last named is applied by spraying a solution of a chromium salt on to a mantle made of alumina and zirconia and igniting the composite product. Mr. Justice Wills considered that the large difference in the oxides used from those employed in the Welsbach mantle removed this hood from the domain of the Welsbach patent which specifically embraces rare earths, whereas none of the oxides adopted by the Sunlight Company can properly be described as belonging to this chemical category. Some stress was also laid in the judgment on the homogeneity of the Welsbach mantle, and the heterogeneity of the Sunlight hood, the latter quality being presumably brought about by the process of spraying the chromium salt on to a skeleton previously rendered coherent. It is difficult to agree with this view, for seeing that the chromium is applied in a soluble state to a porous material it will penetrate the latter to a considerable extent and may even saturate it, forming ultimately a mixture almost as intimate as that produced by the simultaneous application of all the constituent oxides. We are, therefore, inclined to believe, that the essential ground for allowing, as was ultimately done, the claim of the Sunlight Company's patent to be considered no infringement of the Welsbach patent, consists in the nature of the oxides used rather than in the particular mode by which they are formed into a mantle. Thus the Sunlight Company is in the present position of affairs, free to make and sell a mantle of shape substantially identical with that of the Welsbach device. Disregarding the possible result of an appeal, the ultimate success of the mantle depends on its efficiency as compared with that of the Welsbach, and on its prime cost.

The result of the two actions at law, which we have sketched above, goes a long way to confirm what we have said on the occasion of previous patent cases of a similar kind. There is a strong disposition—and on the whole it is a healthy one—on the part of the Courts to uphold, if possible, a patent which is new and useful in a given field, even if foreshadowings of it can be adduced as anticipations. At the same time, although a fairly liberal interpretation of the specification of a patent of this class may be expected, it not infrequently happens either that the specification claims more than can be shown to be practicable, or it omits some method which is afterwards proved to be practicable in a way peculiarly poignant, viz., by its successful exploitation at the hands of a rival in trade. The protection of modifications of a process by separate patents, instead of by numerous claims or an omnibus claim in a single specification, appears to be advisable where the interests to be guarded are large, and opposition is probable. With regard to that aspect of the case which has to do with the evidence of experts on both sides, we should be silent were we not thoroughly convinced of the necessity of iteration. It is not insignificant that the *Times*, not usually over-mobile in its views, has adopted the opinion which we have oftentimes expressed, and declares that picked technical assessors aiding the Court in matters of scientific fact, even as a judge aids a jury on points of law, would much facilitate the hearing of cases lying outside the knowledge of the Court. The attainment of these desirable ends would be a reasonable compensation for the regrettable loss of many a racy story.

THE GROWTH OF STEAMSHIPS.

The return of the vessels in course of construction at the end of the first quarter of the year has some features that are of special interest. There is first shown the fact that out of all the steamships building, steel was the material used except in a trivial quantity; and that is due to the fact that iron and wood are only used in the construction of a few steamers which average 120 tons each, and are thus shown not to be for ocean purposes; whilst, on the other hand, the average of the steel steamships building was about 2250 tons each; and in only a slightly minor degree, similar remarks apply to the sailing vessels that were in course of construction in the same quarter. Out of some 400 vessels building in the United Kingdom, the largest proportion—more than a seventh– is of vessels between 3000 and 4000 tons; and the next largest is for vessels between 2000 and 3000 tons; whilst even in the numerical contrast, the comparison is in favour of the large steamers. In Belfast, the average size of the vessels building is very noticeable, it being over 5300 tons for both sail and steam together, an average which does not seem to be attained by any other of the British districts tabulated by Lloyd's returns. At the same time, it is noticeable that on the Continent there are many vessels of large dimensions in course of construction. At Lubeck, Rostock, and Stettin, out of the vessels building there, seven were of an average of 5900 tons each, but this is the average of the large vessels only—the smallest vessels not being included in the tables. Apart from Germany, there does not appear to be any very large average attained by the builders, though in one of the French districts, the large vessels in course of construction were over 3000 tons each, subject, however, to the remark already made as to the exclusion of small vessels from the returns. The fact, however, may be looked on as settled, that the tendency towards the building of large steamers continues, and that there is now a determination on the part of some of the foreign builders to participate in the orders for the construction of these vessels of greater tonnage. How far it will go remains to be seen, but the large steamships will increase the share of the work of the world over the seas they have been doing.

LITERATURE.

Polyphase Electric Currents and Alternate Current Motors. By SILVANUS P. THOMPSON, D.Sc., &c. London: E. and F. N. Spon. 1895.

THE author delivered a course of four lectures at the Technical College, Finsbury, on the subject of "Polyphase Currents," and has now published the matter with many additions, in the form of the present volume. Little has so far been done in this country with polyphase currents, and the author offers his thanks to German and Swiss firms for many particulars of which he has made use. The addition at the end of the volume of a full bibliography of the subject, and also of a list of British patents, will be found of great use. The book opens with a sketch of the construction of the ordinary alternator, and diagrams show how the current curve is caused to lead or to lag behind the volt curve. In our opinion the graphic method is decidedly the most useful for dealing with this subject; and the Zeuner type of diagram, so familiar to all mechanical engineers, is referred to in the first chapter, and is very useful for showing the momentary pressure on each of the three wires of a linked system. It seems strange to be reminded that the original Gramme machine, built about 1877, was in reality a polyphase generator, but the circuits were kept separate, and there is no reason to suppose that Gramme realised the possibility of linking up the different monophase currents. The author gives, in his usual lucid style, a description of the elementary form of polyphase generator, and this is followed by a description of the now historical machines used for the Lauffen transmission work. The second chapter deals with the combination of polyphase currents. The author makes use of the clock diagram to show how the pressure varies between the line wires of the three-phase system when the coils of the generator are joined up in star fashion, proving that the pressure between two of the leads outside the machine would be 173 virtual volts, while that generated by one coil was 100 virtual volts, and diagrams make this somewhat difficult subject clear.

Economy in copper is most assuredly obtained by the use of the polyphase system, and the author proceeds to point out that the pressure is determined by the lamps, which are not practicable for voltages over 100 to 110. This statement we think requires some correction, in view of the fact that in Bradford and elsewhere lamps have been used with the greatest success for 215 volts; and, in fact, there is little doubt that the three-wire system for direct current will be used very largely with 400 to 480 volts between the outside wires.

The author discusses the somewhat intricate question of the relative costs of copper, and finds that the three-phase system with the lamps joined in mesh, only 75 per cent. of the copper is used which would be required for the single-phase system. Taking the single phase and two wires as 100, the relative costs of the other systems have been put very clearly by Mr. Goerges. It appears that the single-phase three-wire system, with the middle wire half the section of the others, stands at 31·35; while three-phase with four wires has no advantage over the ordinary three-wire system, when the extra cost of fixing the fourth wire is taken into account.

The author uses steam-engine analogies to show how the two-phase and three-phase currents are used to produce the rotary field, and then takes up the history of Arago's experiments on rotating magnetic fields, followed by those of Babbage and Herschel. Walter Baily exhibited the first polyphase motor in 1879, before the Physical Society of London; and this fact will surprise many, who considered that the type had its origin in Germany. Three years later, Deprez laid down an important theorem; and in 1885 Professor Galileo Ferraris, of Turin, arrived independently at the same fundamental ideas as Baily and Deprez. A history is then given of Tesla's work, and also of the work of other electricians, the Frankfort Exhibition naturally supplying the best examples. The author then describes Mr. C. E. L. Brown's machines, and uses the dreadful words "rotor" and "stator" respectively for the moving and stationary parts of the machine. The most important part of the work is probably that which deals with the structure of the polyphase motor, and Chapter VI. deals with the theory of its structure. The volume closes with reference to the work carried out by various firms at the present time; and we may say that it sums up, in a very compact form, information hitherto scattered through the pages of the "Proceedings" of scientific societies and technical journals.

Die Berechnung der Centrifugalregulatoren. Von W. LYNEN. Berlin: Julius Springer. 1895. (The Calculation of Centrifugal Governors.)

THIS work is written by the governmental architect and private tutor of the Royal Technical High School of Charlottenburg, near Berlin, and is the first work we have seen devoted solely to the consideration of the design of the various forms of speed governors for prime movers. The author has evidently made the subject his special study, and although a considerable knowledge of the higher mathematics is required to enable the reader to follow him throughout, yet the various curves and formulas given should be of use to the practical designer. The method used is synthetic, and the action of each single force is considered separately. The general conditions of equilibrium are not discovered by analysis of the forces, that is to say, by static methods, but by the dynamic method. Results are given in the form of a series of curves, and with the aid of curves 1 and 2 the author considers that all weight governors with normal action can be calculated.

One result is a new calculation of the double ball governor, and the author hopes that the efficiency of the cosine governor will be better understood. The subject of axis governors is thoroughly treated, and it is pointed out that spherical or disc weights are to be preferred, for constructional reasons, to the usual club-shaped swinging weights. Numerous examples of calculation are given, in order that the new method of calculation may be clearly understood. The author concludes that the numerous governors in use do not essentially differ from one another, and that the type invented by Watt must be reckoned among the best. The curve of centrifugal force for the three governors at the end of the tables shows a turning point. This type is especially suitable for engines running with great uniformity, such as are used for electric light work, for it is almost astatic at the speed generally used, and has great power at the extreme speeds.

The author considers that, in spite of the importance of governors to engine builders, there is yet a great lack of knowledge on the part of engineers; the reason of this, he suggests, is that governors are built to a large extent by firms who make a speciality of the work. Personally, we think, however, that the latter statement is more applicable to continental than to British practice. Alluding to the analytical method of calculation, the author points out that the weight is considered in conjunction with the gear for moving the sliding piece, and there is a mass of values which only a maker with long practice can understand. He also gives a sketch of the usual figure drawn, and quotes the resulting formula for angular velocity in which there are eight arbitrarily chosen values. The value of ω is less decisive than the change of angular velocity with change of the value, but on this point neither formula nor diagram give any information. The author's method is first to consider the centrifugal force of a rotating mass, then the centrifugal force of a centrifugal pendulum suitable for the governor, and afterwards the forces other than centrifugal forces acting on it. The action of the latter is independent of the rotation of the governor, and depends only upon the nature of the movement. Examination must begin with the most normal motion, and with the simplest changes, and afterwards other and more complex changes can be dealt with. The superiority of the graphic method over the arithmetical is well shown for obtaining rapidly a clear view as to which particular part of the governor must be dealt with to obtain a desired result. The volume should certainly be of value to governor designers who can read German and follow the calculations. A great many different types of governors are dealt with, and the whole of the illustrations are merely line diagrams showing the links and joints.

A Laboratory Course of Experimental Physics. By W. J. LOUDON, B.A., Demonstrator in Physics in the University of Toronto; and J. C. MCLENNAN, B.A., Assistant Demonstrator. London: Macmillan and Co. 1895. Demy 8vo. Pp. 302. Net 8s. 6d. Uncut.

THIS somewhat cosmopolitan production—devised in Toronto, printed in Norwood, Massachusetts, and published in London and New York—is intended to overcome the difficulty experienced by the authors in providing during a limited time ample instruction in the matter of details and methods to large classes engaged in experimental physics in laboratories, and they signify that the book contains a series of elementary experiments arranged as far as possible in order of difficulty. These are intended for students who have but little acquaintance with higher mathematical methods, and they are followed by an advanced course of experimental work in acoustics, heat, and electricity and magnetism intended for those who have taken the elementary course, and who have a more extensive acquaintance with mathematical methods.

The elementary course is arranged under the following headings:—The vernier, the calipers, the cathetometer, the spherometer, micrometer, screw gauge, dividing engine, specific gravity bottle, hydrostatic balance, hydrometers, Mohr's balance, Boyle's law, the volumenometer, determination of capillary constants, the sextant, the goniometer, curvature of mirrors, focal length of lenses, indices of refraction, magnification with lenses, photographic lenses, photometers, specific heat of solids and liquids, latent heat of fusion, and level testing.

The advanced course is divided into three sections:—(1) Acoustics, dealing with the sonometer, equal temperament, transverse vibration of strings, pitch, Lissajou's method of tuning, harmonic motion, overtones, the chronograph, the clock fork, Melde's experiments with strings, Helmholtz's apparatus for combining simple tones, Kœnig's analyser, the manometric flame, velocity of sound and Dœppler's principle; (2) heat, dealing with thermometers, coefficients of expansion of dry air, Favre and Silberman's calorimeter, latent heat of steam, weight of dry air, hygrometry, density of vapour, Dumas' method, coefficient of expansion of metals, specific heat of dry air, pressure of vapours for low temperatures, and Regnault's apparatus for the determination of the pressure at high temperatures; and (3) electricity and magnetism, treating magnetic lines of force, magnetic moments, the declination and inclination compass, intensity of earth's magnetic field, magnetic field of a current, tangent and sine galvanometers, hydrogen and copper voltameters, calibration of galvanometers, galvanic batteries, resistance, temperature, coefficient of resistance, galvanometer resistance, resistance of batteries, E.M.F. determination and absolute determination of resistance by use of calorimeter. Then the determination of gravity by the pendulum and the torsion pendulum furnish matter for two short appendices, and twenty-one tables of various data terminate the book.

From the above synopsis the scope and the arrangement of the matter may be gathered, and as regards the latter it must be admitted that it is by no means happy, especially in the elementary course, as the dodging about from subject to subject it necessitates could not but confuse the student; whilst as regards the former, when considered as a course of practical physics, it is inadequate and incomplete. It is true, on this point, the authors state that the important subject of "Physical Optics" has been omitted because they have not yet mapped out a suitable course of experiments. Then, as regards the treatment, in many instances it is concise and clear, in all it is brief, but in some it is unsatisfactory and cursory; for example, the student is suddenly introduced to the vernier, which is described but not defined; its construction is detailed, but the principles on which it is based are not clearly set forth; examples of its application are given, but the manner of applying it is not explained. Regnault's apparatus for the determination of the pressure of vapours at high temperatures is illustrated by an unworkable diagram with unexplained conventions, and the whole of the directions for working are, "compress the air in the large reservoir, determine pressure by means of the manometer and barometer, and finally take the temperature at the boiler." The object being essentially practical and instructive, the extreme brevity indulged in does not contribute to the utility of the articles. There are more or less copious tables of contents, distributed at irregular intervals, preceding each section in fact, which are far from readily accessible, and as there is neither a general table of contents nor an index, ready reference is impossible, a by no means useful feature in a book for students. The book, however, is well printed and well illustrated, and may serve a useful purpose as a note-book for the particular matters dealt with, and more especially as an adjunct to a more comprehensive course of lectures on practical work.

SHORT NOTICES.

The Volunteers and the National Defence. By Spencer Wilkinson. Westminster, London: Archibald Constable and Co. 1896. Price 2s. 6d.—This is an essay written with the object of giving a comprehensive account of the chief processes of modern war, and to show how the volunteer force may be fitted to do the work of defence with conditions of war what they are to-day. After an introduction and chapter on the scope and method of inquiry into the subject, the author deals with his subject in two main parts, and under the subheads mobilisation, transport, march, quarters, security and exploration, battle, actual conditions of volunteer service, attendances, ranges, principles of modern methods, discipline, and finance.

Lean's Royal Navy List, Containing Special Points of Interest. By Lieut-Colonel Francis Lean—Retired full pay—Royal Marine Light Infantry. No. 74. April, 1896. Published quarterly. London: Witherby and Co. Price 7s. 6d.—This excellent publication is now in its nineteenth year. It was started in January, 1878, and every year of its life has seen improvement in it. It is not too much to say that for fulness of information and careful editing it has no equal. As a book of reference it is invaluable.

The South-Eastern Railway: Its Passenger Services, Rolling Stock, Locomotives, Gradients, and Express Speeds. By the author of "British Railways." With three plates. London: Cassell and Co., Limited, 1895. Price 2s. 6d.—A very convenient little handbook of thirty-two pages, containing much information of interest and value to all who wish to know something of the working of railways. The South-Eastern has a somewhat bad reputation for unpunctuality and slowness. We gather from our author that this is not due to want of locomotive power—indeed it is not easily to find anything better than Mr. Stirling's latest engines—but to the severity of the gradients, the weight of the trains, and the crowded condition of the road. There are diagrams of speed and gradients, and very full particulars of the train service.

The London, Brighton, and South Coast Railway: Its passenger Services, Rolling Stock, Locomotives, Gradients, and Express Speeds. By the author of "British Railways." With two plates. London: Cassell and Co., Ld. 1896. Price 3s. 6d.—A capital little book of 56 pages. The author has more to say about the Brighton than about the South-Eastern Railway. The method of treatment is, however, the same. The particulars of locomotive work are very complete and interesting.

BOOKS RECEIVED.

The Cheque Bank Handbook, 1896. Second edition. List of principal banks and agents.

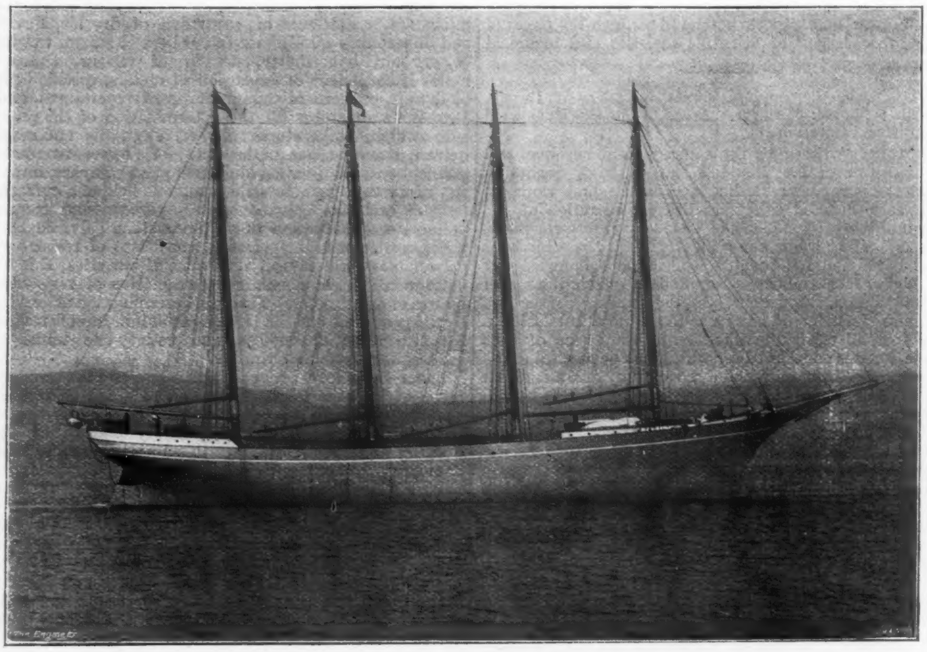
The Progress of Artillery. Naval Guns. By James Atkinson Longridge, M. Inst. C.E. London: E. and F. N. Spon. 1896.

An Elementary Treatise on the Calculus, for Engineering Students. With numerous Examples and Problems worked out. By John Graham, B.A., B.E. London: E. and F. N. Spon. 1896.

Les Rayons X et la Photographie à travers les Corps Opaques. Pat Ch. Ed. Guillaume, Adjoint au Bureau International des Poids e. Mesures, D.Sc. Paris: Gauthier-Villars et Fils. 1896. Paper 127 pp.

A REUTER telegram from Simla says heavy floods in the Panjkora Valley have damaged the bridges at Chutiatan, and have destroyed all the bridges on the river above Dir. It is hoped, however, that the forwarding of reliefs to Chitral will suffer no delay.

THE FOUR-MASTED SCHOONER HONOLULU



A NOTABLE CLYDE-BUILT SCHOONER.

The attention now being directed to the subject of the manning of ships, coupled with the constant aim of shipowners to avail themselves of any economy possible in that direction, while at the same time securing the needful efficiency, are considerations which should render some details of the new steel fore-and-aft schooner Honolulu of interest. This vessel—of which we give an illustration reproduced from a photograph kindly furnished to us by her builders, Messrs. Robert Duncan and Co., Port Glasgow—besides being the largest steel fore-and-aft schooner ever built in this country, is of a type very rarely met with in British waters, and altogether a novelty as emanating from the stocks of a Clyde shipyard. She has been built for the timber-carrying trade to the order of Mr. John Ena, merchant and shipowner, Honolulu, for whom Messrs. Duncan and Co. have before built sailing vessels of the ordinary kind. As will be seen from our illustration, the Honolulu, both in the matter of hull and of rig, has features distinguishing her from the ordinary sailing ships of modern times, at least so far as British practice is concerned. This was conspicuously made evident in the course of last month, when the Honolulu, while loading a general cargo prior to departing on her maiden voyage, lay alongside some of these full-rigged vessels in the Queen's Dock, Glasgow. Vessels of the type of the Honolulu, however, are no novelty on the Pacific, and along the west coast of America; many of these being double her tonnage, which is about 1000 tons gross.

Our illustration conveys a fair idea of the peculiarities of rig, of the vessel, and perhaps also of her hull. Features which at once attract notice are the great sheer, graceful clipper bow and bowsprit, the four lofty pole-masts of equal length, and the simplicity, not to say meagreness, of the rigging gear. The vessel's general proportions are somewhat extreme as compared with the proportions ordinarily adopted in modern sailing vessels, while the hull form is quite yacht-like in its fineness of lines. The vessel's dimensions are 225ft. length over all, or 210ft. between perpendiculars; 42ft. beam, and only five beams to the length; and 18ft. 6in. depth of hold. The rise of floor is of the unusual height of 6ft., giving a relatively small midship area, and, combined with the fineness of water-lines, giving a coefficient of form resembling that pertaining to those renowned tea clippers built in our midst in the "fifties," which made such marvellous passages to and from the Far East. The Honolulu has four huge steel pole-masts, each of them about 140ft. in height from keel to truck, and with an immense fore-and-aft sail, hooped to the mast and laced to gaff and boom. These four sails, and three jib sails which are carried forward, give a total spread of canvas considerably greater in proportion to displacement than the total sail area of any square-rigged vessel afloat.

The structure of the vessel is of the strongest description for the safe carrying of heavy timber cargoes, somewhere about 1¼ millions superficial feet of lumber being her complement. Save the collision bulkhead forward, the interior of the vessel is unobstructed from end to end, and there is no 'tween decks. The main deck from stem to stern is entirely of steel, with strong bulwarks supported by heavy bulb web stanchions every 4ft. apart, in order to secure safety in carrying the immense deck-loads common in the particular trade for which the vessel is intended. The forecastle deck is also of steel, while the poop deck is laid with specially selected Oregon pine. Besides having unusually large hatchways forward of each mast for timber cargoes, there are fitted in the bow and stern large ports capable of taking in the heaviest timber of almost any length, the timber being put on board by an ingenious arrangement of leads and pulley blocks worked from a special steam winch of extra power, situated in the large deckhouse abaft the forecastle. This steam winch, combined with a large multitubular boiler, is specially designed with warping drums, both horizontal and vertical, and every appliance and gearing, not only for loading and discharging deckloads of heavy timber, but for rapidly hoisting and working the vessel's immense fore-and-aft sails. This combination of boiler, winch, and gear has been supplied by Messrs. Murray Brothers, of San Francisco, who are familiar with the requirements in this installation of special machinery on board ships of this type. In case of need, steam can be raised in this boiler in about ten minutes to a pressure of 200 lb. per square incn—an immense advantage where all the spars, sails, and gear are of the heaviest description. Manual labour is saved to a very considerable extent, and a smaller number, or less experienced seamen, is capable of managing the sails, ropes, &c. The style of rig adopted, in fact, and the equipment of the vessel generally, admit of her being efficiently worked by about half the number of seamen which would be required under ordinary British regulations.

Steam from the boiler above-mentioned also drives a powerful capstan windlass of Emmerson and Walker's make, and also actuates one of Tangye's patent duplex steam pumps capable of throwing 2000 gallons of water per hour. This appliance will be invaluable in the event of fire or other accident to the vessel or cargo. A set of Mills' patent pumps is fitted amidships, which can also be worked from the steam winch through the medium of messenger chains. The entire outfit of blocks for the vessel is of a special and very expensive description made by Messrs. Laird and Sons, Irvine, from patterns and particulars supplied by its owner and adapted for the excessively hard work they have to accomplish. The rudder is of a design also furnished by the owner, and which is seldom seen in large sailing vessels in home waters, being abnormally broad at the bottom, tapering to nothing at the load water-line, for the purpose of manœuvring the ship quickly when going through narrow channels amongst the Sandwich Islands. The vessel, which is classed "British standard" with the British Corporation of Shipping, Glasgow, was built and equipped under the superintendence of Captain William Thonagel, of San Francisco, who has had great experience, and is well known in the Pacific trade.

THE RAILWAY ZONE TARIFF SYSTEM IN RUSSIA.

Since the introduction in February, 1879, of the special Government tax on railway passenger tickets, 25 per cent. on first and second-class, and 15 per cent. on third-class tickets, the passenger rate on Russian railways per mile has been 2·15d. per mile first-class, 1·61d. second-class, and 0·827d. third-class. From time to time attempts were made to reduce these rates, but all that was accomplished was a reduction in the three classes of 3 per cent. per mile in 1880, and 6·8 per cent. in 1891. The comparatively small use of the Russian railways showed conclusively that the rate was too high. While in 1891 the number of railway passengers in Great Britain was 817,000,000, in Germany over 315,000,000, in France 208,000,000, and in Belgium about 57,000,000, the number conveyed in Russia was only 43,500,000. Notwithstanding the enormous distances in Russia, more than one half of the passengers conveyed did not travel over 33·15 miles, and only 6 per cent. of the total travelled 199 miles. The number of coaches used is, therefore, very small. On the average for each first-class passenger five places were available, for each second-class passenger not less than four places, and on some lines twenty places, and for each third-class passenger more than two places.

The good results which followed the adoption of the zone tariff in Hungary led the Russian Government to pursue a similar course, and the new passenger tariff was introduced on 1st December, 1894. The zone tariff begins at 199·56 miles, between that point and 1011·3 miles there are 36 zones, viz., 199·56—331·5 miles, eight zones; 332·16—470·73 miles, seven zones; 471·39—656·37 miles, eight zones; 657·03—1011·3 miles, thirteen zones. After this distance every 33·15 miles is counted as a zone.

The cost of a third-class railway ticket for a distance of from 0·663 to 199·56 miles is: up to 106·08 miles, 0·824d.* per mile; from 106·74 to 198·9 miles, 0·516d. per mile. The charge for a second-class ticket is one-half, and for a first-class ticket two and a-half times higher than for a third-class. Children from five to ten years pay in each class half a full fare. Baggage to the amount of 36·112 lb. is allowed for each full ticket. The rate for transportation for each hundredweight of passenger's baggage is up to 215·48 miles, 0·369d. per mile; beyond that distance 9·64d. per zone is added. The new passenger tariff makes long-distance travelling by rail very much cheaper than under the former system. The following shows the comparative cost of a third-class ticket for distance up to 198 miles under the old and new systems:—

Distance.	Old tariff. £	s.	d.	New tariff. £	s.	d.
106·08 miles	0	7	8¼	0	7	8½
132·60 „	0	9	1¼	0	8	5
198·90 „	0	13	7¾	0	11	3¼
265·20 „	0	18	2¼	0	13	9¾
331·50 „	1	2	9¼	0	16	4
397·80 „	1	7	4	0	18	6¾
464·10 „	1	11	10¼	1	0	9¼
530·40 „	1	16	5	1	2	8
596·70 „	2	0	11¾	1	4	6¾
663·00 „	2	5	6¼	1	6	5¾
994·50 „	3	8	3¼	1	14	6¼
1326·00 „	4	11	0¼	2	0	10¼
1657·50 „	5	13	11¼	2	7	2¾
1989·00 „	6	16	7	2	13	6¾

The reductions vary from 7·76 per cent. at 132·6 miles to 60·8 per cent. at 1989 miles, and average 46·81 per cent. The reduction between certain known places is still more marked, viz.:—St. Petersburg to Moscow, old fare £1 7s. 5¾d., new fare 19s.; Riga, old fare £1 7s. 10½d., new fare 19s.; Verballen, old fare £1 18s. 2¾d., new fare £1 3s. 5¼d.; Nishni-Novgorod, old fare £2 6s. 2½d., new fare £1 6s. 7¼d.; Warsaw, old fare £2 7s. 9¾d., new fare £1 7s. 3¼d.; Kharkov, old fare £3 0s. 8d., new fare £1 11s. 8d.; Kiev, old fare £3 7s., new fare, £1 14s. 2½d.; Odessa, old fare £4 3s. 0½d., new fare £2 0s. 6½d.; Piatigorsk, old fare £5 2s. 3d., new fare £2 3s. 8¼d.; Vladikavkaz, old fare £5 9s. 6¾d., new fare £2 5s. 7¼d.; Cheliabinsk, old fare £5 17s. 3½d., new fare £2 8s. 1½d.

The difference in the rates of second-class travelling is still greater, the fare from St. Petersburg to Verballen having been reduced from £3 14s. 8¾d. to £1 15s. 1¾d.; that to Warsaw from £4 13s. 6½d. to £2 0s. 10¼d.; and that to Odessa from £8 2s. 5½d. to £2 17s. 11½d. The result is that people of small means, who had to travel long distances by third-class, can now go second-class for less money. How little the first and second-class have been used is shown by the following figures:—

Proportions of Passengers carried.

Years.	First-class. Per cent.	Second-class. Per cent.	Third-class. Per cent.	Fourth-class. Per cent.
1883	2·02	9·62	86·05	2·31
1889	1·49	7·54	88·80	2·17
1891	1·36	6·86	88·81	2·97

The following shows the difference between the old and new tariffs for every hundredweight of baggage:—Distances of 198·90 miles, old tariff, 6s. 7¾d.; new tariff, 6s. 2¼d. 397·80 miles, old tariff, 13s. 3½d.; new tariff, 11s. 10½d. 596·70 miles, old tariff, 19s. 11¼d.; new tariff, 16s. 8d.; 994·50 miles, old tariff, £1 13s. 2¾d.; new tariff, £1 4s. 7¾d. These reductions, ranging from 8 per cent. at 198·90 miles to 25·12 per cent. at 994·50 miles, and averaging 16·1 per cent., are much less for long distances than those for passengers.

It was expected that the Russian railways, through the introduction of the new tariff, would lose yearly £1,894,202, provided traffic remained the same. According to the former tariff the railways earned £8,061,754 from the passenger traffic, and according to the new tariff they could only expect to earn £6,665,885; but it is hardly possible that such a loss could occur, experience thus far showing the contrary. For instance, when in 1881-82, on the Warsaw-Vienna Railway, a lower rate was introduced on fourth-class tickets, the number of passengers increased from 1,600,000 to 2,000,000; but as soon as the rate advanced again the number of passengers returned to the former figures. The Griaze-Tsaritzine Railway had the same experience. It made a reduction of 0·43d. per mile, and not only did the number of passengers become greater, but the number of miles travelled also increased. In 1891, when the rates were reduced to the people of the needy districts, it was shown that, in comparison with 1890, the number of persons who used the lower rates increased by 44·3 per cent., and the number of miles travelled by 80 per cent. If the passenger traffic should increase on account of the great reductions under the new tariff in proportion to that mentioned in the foregoing cases, the prospects for the Russian railways are bright, and other countries may follow the Russian example. Later advices state that instead of the expected deficiency of £1,894,202, the receipts last year rose to £9,183,333, an increase of £1,121,579, or 13·92 per cent.

According to the United States Consul-General at St. Petersburg, it seems from the number of railway projects on foot as if Russia were about to enter upon a period of unusual railway activity. Last year, when the zone tariff had been working for some time, a syndicate of Berlin and Paris financiers was formed at Warsaw for the purpose of proposing to the Russian Government an extensive scheme of railway construction, comprising the construction of a railway from St. Petersburg to Kiev, the renting of the existing lines joining Kiev, Kazatin, and the Uman-Elisabetgrod branch, and the construction of a line from Uman through Volnesensk to Odessa, without a Government guarantee.

---

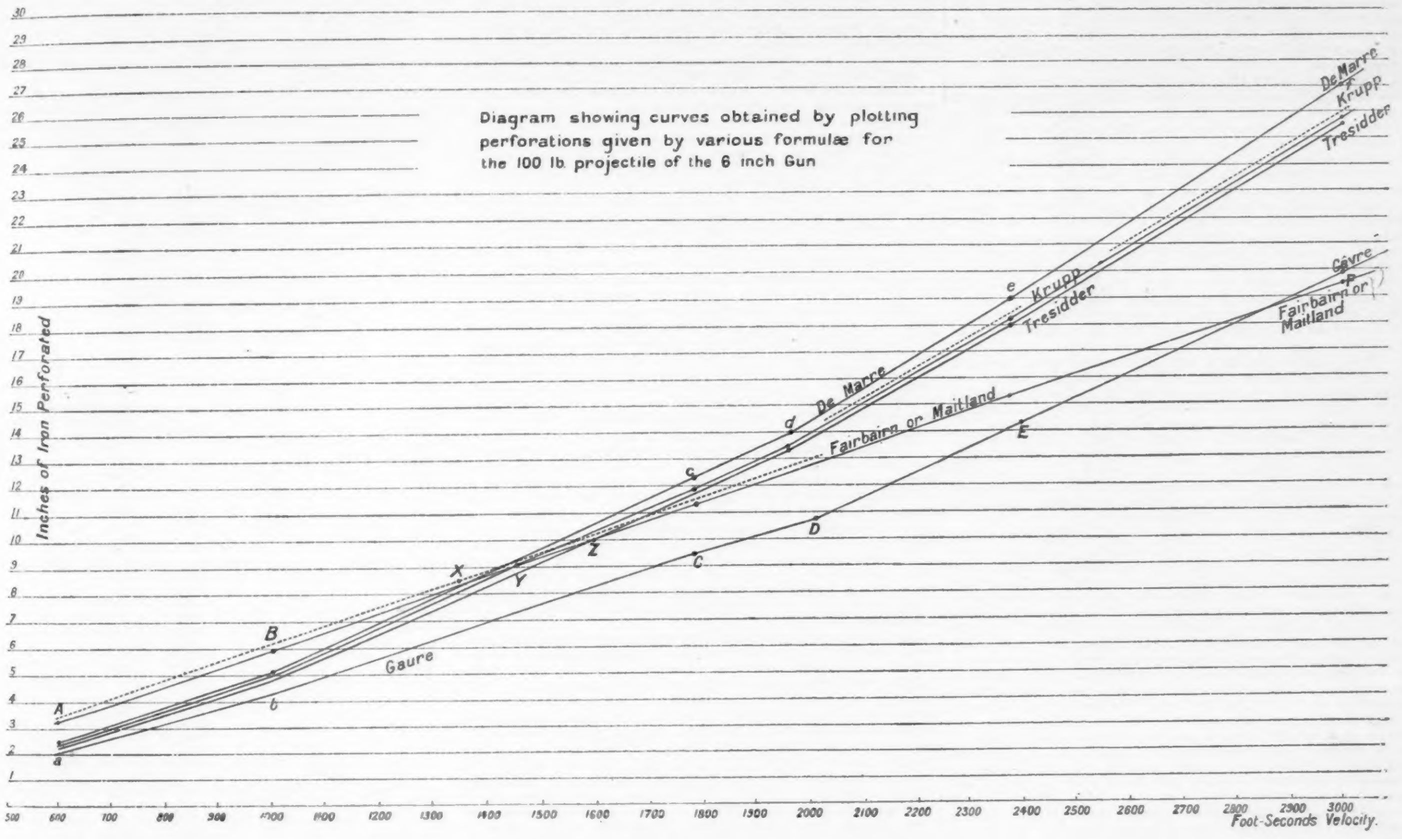
* As the value of the rouble has fluctuated from 3s. 2¼d. in 1874 to 1s. 5½d. in 1895, all rates in this paper are based on its gold value 3s. 2d.

New Walrand-Legenisel Plants.—Walrand and Legenisel, of Paris, have just completed and put in operation two of their special types of plant at the works of the Société Franco-Russe, and the Baltic Works, in St. Petersburg. At the first-named works there is only one 300 kilog. converter, while at the latter there are two of 800 kilog. As a result of the success attained at the last-named works, the authorities of the Obouchov State Foundry have decided to put down a plant of the same type.—*American Manufacturer.*

Gainsborough Waterworks.—At their meeting on the 13th inst. the Gainsborough Urban District Council, after passing a vote of condolence with the widow and family of their late engineer, Mr. Jabez Church, unanimously appointed Mr. Church's partner, Mr. Percy Griffith, as engineer to continue and complete the waterworks extensions now in progress. Since our last reference to these works, the first portion of the large boring has been successfully completed. This is 320ft. deep and 36in. diameter, and is lined with 30in. wrought iron tubes, the annular space around the tubes being filled with 3 parts fine sharp sand and iron borings to 1 part of Portland cement. The last lengths of the tubes were lowered on March 10th, and after carefully testing them for verticality, the cement was filled in behind them till it finished off level with the top of the last tube. As the boring was so much larger than the tubes, the whole weight of the 290ft. of tubes—upwards of 18 tons—had to be suspended on the overhead gear. Ample precautions were, however, taken by the contractors, Messrs. E. Timmins and Sons, and the whole of the operations were conducted without mishap or accident of any kind. The next section of the boring is now in progress, and is being bored 24in. in diameter. If it is found possible to continue this to the total depth required to be tubed—another 440ft.—without any difficulty from infall, &c., the whole of this section will have 18in. tubes lowered into it, and filled in with cement as in the first section. It will be remembered that this boring is to be carried down to a total depth of 1450ft., and is to finish not less than 18in. diameter at the bottom, so that the endeavour to avoid any driving of the tubes by the system described will be fully appreciated by anyone experienced in boring operations.

FORMULÆ FOR CALCULATING THE PERFORATION OF ARMOUR.

Captain Tresidder, the well-known member of Brown's Armour Plate and Steel Works, last year suggested a formula for perforation which might, he urged, be adopted with advantage internationally, on the following grounds: (1) Close agreement with actual results obtained at various velocities; (2) theoretical soundness; (3) simplicity. There is considerable support for the claims thus advanced—that is to say, this formula gives results for high velocities which are much more nearly correct, so far as we have evidence, than do the recognised British formulæ of Maitland or Fairbairn. For low velocities, we believe the last named formulæ, which are practically identical, give good results—better, we are inclined to think, than Tresidder's; but in the present day high velocities are much more important than low ones, because the former are more likely to be employed. Then, again, without question, Tresidder's formula is more simple than others. He has also embodied it in a slide rule which is an actual luxury for those who have to calculate perforations. With regard to theoretical soundness, authorities do not appear willing to admit that Captain Tresidder's claim is proved. He has not had much opportunity of advocating his views, and mathematicians are slow to be convinced on a question like this, so that at present the formula stands on its working merits, and the working merits of any formula now are difficult to determine fully, because firing ordinarily takes place against steel plates treated and hardened in such a variety of ways as to make comparison very difficult.



So far as we can speak with confidence, the whole question stands as follows:—We have in past years fired at comparatively low velocities at wrought iron until experience enabled us to arrive at a trustworthy formula for these conditions. Such a formula was obtained by a combination of such elements as are theoretically sound, with such empirical terms and corrections as caused a fairly correct result to be obtained over a certain range of conditions. As armour developed, difficulties increased. Steel, chilled iron, and steel-faced armour replaced wrought iron. If these always yielded in the same way as wrought iron, that is, by perforation, it would be easy to arrive at a relation between the resistance of any particular steel plate and that of wrought iron of the same thickness, but when plates yield by fracture the conditions are greatly changed. For example, in perforation, the smaller the diameter of a shot, the smaller is the hole it needs to make in order to pass through, and the less is the work required to make such a hole. If, on the other hand, the plate yields in preference by fracture, it is a question if the diameter of the shot enters into the calculation. It appears probable that the action is the splitting action of a pointed wedge struck with the plate, and both plate and shot generally break without a hole the size of the shot's transverse section being made at all. Chilled iron and wrought iron offer the extreme examples of what were then termed "hard" and "soft" armour, the former yielding wholly by fracture, the latter wholly by perforation. Probably the former action depends mainly on the total striking energy of the shot, affected, no doubt, also by its tenacity, on which depends the amount of work delivered before the shot breaks. The latter depends directly on the striking energy, and inversely on the diameter of the hole to be made, that is, the smaller the hole the greater the penetration. How widely the powers of perforation and of fracture differ may be seen from the fact that for many years there were on board the Nettle two guns available for testing plates, an old-fashioned 10in. gun and a new type 6in. piece. The perforation of the two was about equal, the smaller gun attaining to an equality with the heavy old-fashioned one, by having less work to do in making a 6in. hole than the heavy shot had to perform in making one of 10in.

For the work of fracture the small projectile had no such advantage, and it is probable that efficiency of the two shots might be nearly in proportion to their respective striking energies, and these were nearly in the proportion of two to one; so that while the 10in. and 6in. shot were able to perforate about the same thickness of soft armour, the former delivered about double the shock of the latter on hard armour. As armour developed further, it generally took an intermediate form, yielding partly by perforation and partly by fracture, and this may be said to be the case at the present time. Calculation also becomes more difficult from the liability of the shot to break against the hard face. As we have asked before now, who can calculate what a tool may do in the act of breaking? We may certainly understand how the effect may be greater under some conditions than others. For example, at a high velocity a shot may perform work before the line of least resistance is found, and thus cause surprise by behaving much better than at a lower velocity. On the other hand, at a still lower velocity, the shot may not break at all, and thus a worse result may be obtained at an intermediate velocity than at either a very low or very high one. These effects have been seen in experiments; we may conjecture why, but any approach to calculation is difficult. A question of this kind can only be dealt with systematically. The elements must be separated and investigated one by one. The first step needed is to ascertain the laws relating to perforation of wrought iron at the high velocities which have now come in. At present formulæ which have been empirically adjusted, so as to give good results over a certain range of velocities, are employed for those much higher with very little guidance as to their suitability. The little evidence we have is to the effect that the English official formulæ give perforations which are far too small; indeed, at Shoeburyness on one occasion a 6in. shot, fired even at the moderately high velocity of 2378 foot-seconds, passed clean through plates 17in. thick, and went on about 1600 yards, when by the old English formulæ it should have only perforated a 16in. plate, and should not have entered nearly 16in. into a 17in. plate. Krupp's formula, and that of De Marre, appear to be much more correct for high velocities; but we have very scanty data to support them. The relation borne by the respective formulæ to each other is best seen by tracing the curves showing the results they give. The diagram herewith exhibits the perforations given for the 6in. gun firing a 100 lb. projectile by the formulæ of Fairbairn, De Marre, Krupp, Tresidder, and a Gâvre formula.

The ordinates give the perforation in inches of wrought iron due to the velocity in feet-seconds registered along the abscissa. The figures and points of registry are those taken and worked out by Captain Tresidder in his pamphlet "Notes on Formulæ for Armour Piercing." These are as follows:—

Projectile.	Striking velocity f.s.	Perforation in inches by				
		Fairbairn.	De Marre.	Krupp.	Tresidder.	Gâvre.
6in. shot of 100 lb. ...	600	... 3·2	... 2·30	... 2·30	... 2·28	... 2·00
	1000	... 5·9	... 4·98	... 4·95	... 4·90	... 4·17
	1780	...11·2	...12·15	...11·80	...11·64	... 9·45
	1950	...12·4	...13·93	...13·48	...13·35	...10·78
	2380	...15·3	...19·00	...18·22	...18·00	...14·38
	3000	...19·5	...27·05	...25·80	...25·47	...19·98

On the diagram the curves pass through the points calculated and plotted at the different velocities, these points lying on or between A *a*, B *b* and C *c*.

Fairbairn's, it will be seen, gives the highest result at low velocities, but soon falls below most of the others, the curve crossing that of De Marre at X about 1350 foot-seconds, Krupp at Y at about 1460 foot-seconds, and Tresidder at Z at about 1600 foot-seconds.

From about 1200 to 1750 all the variations in the results fall within an inch, but at 3000 foot-seconds Fairbairn gives 6½in. less than De Marre, which, as has been repeatedly pointed out, is a monstrous discrepancy. The Gâvre formula gives also strangely low results throughout. We think, however, that this formula has been abandoned generally in favour of that of De Marre. Those then with which we are most concerned are the formulæ of Fairbairn or Maitland, De Marre, Krupp and Tresidder. The first has been long used officially, and is not yet actually discarded. Krupp appears to agree with our Shoebury trial better than De Marre's, and Tresidder gives practically very nearly the same results, the difference mainly being that in Krupp's the element of weight tells more, so that with a long projectile with great weight in proportion to its calibre, Krupp would give greater perforation. Tresidder's formula is commonly written thus, for working by logarithms:

$$t^2 = \frac{W v^3}{d} \times \frac{1}{\log^{-1} 8{\cdot}8410},$$

where t = the thickness in wrought iron in inches, w the shot's weight in pounds, v the striking velocity in foot-seconds, and d the diameter of shot or calibre of the gun in inches. Krupp's formula, using the same notation, is—

$$t^{\frac{4}{3}} = \frac{W v^2}{d^{\frac{5}{3}}} \times \frac{1}{\log^{-1} 5{\cdot}7770},$$

Raising all Krupp's terms to a power of $\frac{3}{2}$, we get

$$t^2 = \frac{W^{\frac{3}{2}} v^3}{d^{\frac{5}{2}}} \times \frac{1}{\log^{-1} 8{\cdot}6664}$$

This obviously approximates nearly to Tresidder's formula.

It is very desirable that the subject of perforation of wrought iron at high velocities should be investigated, not by firing on a large scale, when only a few rounds can be allowed on the score of economy, but with some small piece, when, at comparatively trifling expense, whole series might be obtained. A well planned series would, at all events, give sound data for the scale on which it was carried out, and furnish a formula which would be gradually tested by every round fired on a large scale, and those who have most experience in these matters believe that it would be found to hold good. It might be possible after that to devise something to teach laws of fracture, although this is difficult and far less important than perforation.

In the meantime, we can only act on what data we have before us. It is not to be expected that we should give up using formulæ for the low velocities for which they have been proved good. For high velocities, unfortunately, there is evidence that their use causes gross mistakes. The most natural course to take then would be to keep to our old Maitland or Fairbairn formula up to 1450 or 1600 foot-seconds, at which points it agrees with Krupp and Tresidder respectively. Here we might "shunt," as it were, on to one of these curves, and use the Krupp or Tresidder formula for the higher velocities.

There is, however, an objection to such a course—namely, that service tables exist which it is undesirable to alter unless we know that we are right in doing so. Now, in the present state of our knowledge, we have no certainty that we are correcting for the better until the difference becomes a large one, when it is necessary to act. On the whole, then, the best present course is to let our tables stand unaltered up to 2000 foot-seconds velocity. This covers all but the newest guns. For velocities over 2000 foot-seconds we may be confident that Krupp's or Tresidder's formula is much nearer the truth than the old ones, and we are inserting new velocities for new guns rather than making corrections in our existing tables. There remains the evil that a projectile striking at a velocity just below 2000 and one just above 2000 foot-seconds are calculated on different systems, and a wide gap exists between them. This is shown on the diagram by the dotted line which takes the course we suggest, and abruptly leaves the Fairbairn curve for that of Tresidder at 2000 foot-seconds; but perhaps it is a good thing that we should have an inconsistency made apparent like this, to remind us of our unsatisfactory condition of ignorance. At all events, we can suggest nothing better at the present time.

THE MOBILITY OF MOLECULES OF CAST IRON.*

By A. E. Outerbridge, jun., Philadelphia, Pa.

It has been generally accepted as a fact that cast iron, under the influence of repeated shocks, becomes brittle, and will finally break under a blow which otherwise it would have withstood. It will probably surprise metallurgists, therefore, to learn that experiment disproves the supposed fact, and establishes exactly its opposite.

The result of about a thousand tests of bars of cast iron of all grades, from the softest foundry mixtures to the strongest car wheel metal, enables me to assert with confidence that, within limits, cast iron is materially strengthened by subjection to repeated shocks or blows.

It is very well known that the usual process of annealing castings—such, for example, as car wheels—increases their strength by relieving cooling strains. But, it is not well known—if known at all prior to this announcement—that the molecules of cast iron are capable of movement—for they do not touch each other†—without the necessity of heating the casting, and that they can thus rearrange themselves in comfortable relation to their neighbours, and relieve the overcrowding near the surface of the casting. In more technical words, a molecular annealing may be accomplished at ordinary temperatures which will release the strains in the castings, precisely as does annealing by slow cooling in heated pits or ovens. A statement so surprising should not be made without sufficient data to establish its correctness beyond cavil, since it is contrary to former belief, certain to be questioned, and properly so. Before proceeding to give a record of the experiments which have been made, and which can be readily repeated by any one, a brief history of the origin of the first observation leading thereto may be interesting.

In 1883—being at that time engaged in metallurgical work at a large car wheel establishment—I noticed that chilled cast iron car wheels rarely cracked in ordinary service after having been used for any considerable time; if wheels did not crack when comparatively new, they usually lasted until worn out or condemned for other causes. No application was made of this observation at that time, further than to institute a careful investigation of the condition of the annealing ovens when some new wheels were returned cracked, under the supposition that the wheels were not well annealed, and an equally careful revision of the iron mixture to ascertain whether the fault lay therein.

In 1894, a large number of "transverse test bars," 1in. square and 15in. long, accumulated in the foundry of Wm. Sellers and Co., Incorporated; and, to expedite the cleaning of sand from their surfaces, they were all thrown into an ordinary "tumbling barrel" with other castings, and knocked about for several hours. When these test bars were broken upon the transverse testing machine, and the records were tabulated, I noticed with surprise that the average strength of the entire series was considerably higher than was usual with similar iron mixtures. This difference was fortunately so marked as to cause a careful inquiry—first, into the condition of the testing machine; then as to the chemical composition of the metal in the bars. The machine was found to be in good order, and the metal was normal. A card pattern was then made, upon which twelve test bars could be moulded side by side in one flask, and poured from one runner. Six of these bars were placed in the tumbling barrel, the other six were cleaned of adhering sand with an ordinary wire brush, and the twelve bars were broken upon the machine. All of the bars which had been subjected for about four hours to incessant blows in the tumbling barrel were stronger than their companion bars—the actual gain varying from 10 to 15 per cent. This metal was soft foundry iron.

These tests were repeated on several consecutive days with similar results, while various theories were suggested, and clues were followed, to detect the hidden cause of this strange fact.

One plausible explanation offered was, that the rubbing of the bars together in the tumbling machine slightly rounded the corners, and thus prevented a starting-point for a "check" or break of the bar under the strain in the testing machine.

This theory was soon overthrown by tests. The corners of six bars were rounded by filing—the companion bars not being filed; all of the bars were then cleaned with a wire brush and broken upon the transverse testing machine, and there was no apparent gain in strength in the bars with rounded edges. Round test bars—1⅛in. in diameter, 15in. long—were then poured from one ladle of iron. Some of these were cleaned in the tumbling barrel, and all that were so treated proved to be much stronger than the companion bars which had been merely cleaned with a wire brush.

This process of eliminating false theories was continued, until finally a new explanation occurred to me, and simultaneously a convincing test of its accuracy suggested itself. The explanation, as indicated in the title of this paper, is the mobility of the molecules of cast iron, at ordinary temperature, when subjected to repeated shocks.

The crucial test referred to consisted in subjecting six bars to 3000 taps each with a hand hammer upon one end only of the bar. All the bars so treated showed a gain in strength equivalent to the gain exhibited by bars which had been subjected to blows over the entire surface for several hours in the tumbling barrel. Here was a new revelation, of scientific interest to the metallurgist, and suggesting to the founder the possibility of annealing castings at ordinary temperatures by availing himself of this molecular mobility. It proves also that we have for many years been unconsciously accomplishing this beneficial result, at least partially and irregularly, by tumbling small castings in a revolving barrel, merely for the purpose of conveniently cleaning them from adhering sand.

Another interesting fact was incidentally brought out in this investigation, namely, that the strain caused by cooling, and the consequent weakening, exists even in the smallest castings, where we would naturally expect that the cooling would be practically uniform throughout the section; moreover, that even in bars of uniform section, such as 1in. test bars, the weakening by cooling strains sometimes amounts to more than 10 per cent. of the ultimate stress. Repeated tests show that ½in. bars, in which the fracture is comparatively uniform to the eye throughout the section, are subject to the same law. Other tests show that the comparative difference in transverse strength between bars which have been hammered on their ends, or otherwise subjected to the process of molecular annealing by vibration when cold, and companion bars cast in the same flask, not so improved, depends to a certain extent upon the number and force of the blows, and to a still greater degree upon the grade of cast iron tested. For example:—

(1) Greater relative difference is found in hard mixtures, or strong iron, than in soft mixtures, or weak iron.

(2) Greater relative difference is found in 1in. bars than in ½in. bars, and somewhat greater difference in 2in. bars than in 1in. bars.

Impact tests.—The foregoing experiments having been repeated sufficiently often to satisfy me of their absolute reliability—and really remarkable uniformity—a new series of tests was commenced for the purpose of ascertaining how many blows were required, and approximately what force was needed to accomplish the desired object of relieving cooling strains. A new machine was constructed for this purpose, and light was soon thrown upon these questions, while still other important questions were suggested and answered by the use of the same machine.

The impact machine first used was an old one, and consisted of a weight fastened to an arm swinging in a graduated arc. The friction of the pivot and the crude construction of the machine precluded even an approximately accurate measurement of the force of the blow delivered.

The new machine consisted of a frame or yoke, marked in inches, and a wedge-shaped weight, adapted to the size of the bars to be tested, which was raised vertically to any desired number of inches, and when released, fell by gravity in free space, striking the bars in the centre between the supports, which were 12in. apart. A 14 lb. weight was adopted for testing 1in. bars.

Impact testing machines have long been used, and car wheels are accepted or condemned according to tests made upon such machines. It has always been maintained that each blow of the "drop" weakened the casting, and that the final blow was only a record of the residual cohesion remaining in the metal after previous blows had proportionately weakened it. In the case of a thoroughly annealed car wheel, this reasoning may be sufficiently correct; but as applied to impact testing machines used for testing unannealed bars, the argument is absolutely fallacious. In such cases the impact machine is itself a means of molecularly annealing test bars, as I will now demonstrate.

Impact experiments.—Six of the 1in. square test bars, cleaned with the wire brush, were broken upon the impact machine by dropping the weight from a sufficient height to break each bar at the first blow. The six companion bars, also cleaned with the brush, were then in turn subjected to blows, numbering from ten to fifty each, of the same drop weight, falling one-half the former distance, these blows being insufficient to break the bars. The weight was then permitted to fall upon each of these bars in turn from the height at which the six bars previously tested had been broken at the first blow. Not one bar broke. Two, three, six, ten, and in one case fifteen blows of the same drop from the same extreme height were required to break these bars. In another similar case the weight was dropped once from the former height, then raised by inches until four more blows, each being 1in. higher than the last, had been delivered before breaking the piece. Subsequent tests showed still greater gain in strength.

The next experiment with the impact machine was designed to test molecularly-annealed bars from the tumbling-barrel, in comparison with untreated companion bars, under one heavy blow. It was found that a blow of sufficient force to break the unannealed bars with one fall of the weight must be repeated from five to twenty times—depending mainly upon the nature of the iron mixture—to break the molecularly-annealed companion bars. By careful experiment in the manner described, it was shown that the ultimate strength of the bars which had not been through the tumbling-barrel could be increased, by successive slight blows upon the impact machine, to an equality with their companions.

The experiments here related in a running conversational narrative form a part of the daily records of metallurgical work at the foundry of William Sellers and Company, Incorporated, Philadelphia; and the aggregate number tabulated is very large. All the tests corroborate fully the statements here made; and they are susceptible of repetition and confirmation by anyone interested in work of this character. They form a part of a long series of investigations—extending over a period of fifteen years—upon the relation between the physical nature and chemical composition of cast iron; they have served to throw light upon phenomena hitherto obscure connected with the design, construction, &c., of castings; and, as it is believed that they contain the germ of a new scientific discovery valuable in its principle to all workers in these fields, these brief notes are presented to the Institute in response to the invitation of its secretary, and through the courtesy of the firm of William Sellers and Company, Incorporated, for whose benefit and at whose cost they were primarily made.

In conclusion, it should, perhaps, be observed, to avoid the possibility of misunderstanding, that the molecular annealing of cold cast iron by successive slight shocks differs from annealing by heat in that it has no power to change the condition of carbon in the casting or to alter the chemical constitution in any way. All that is claimed is that every iron casting when first made is under a condition of strain due to difference in the rate of the cooling of the metal near the surface, as compared with that nearer the centre, and also to the difference of section; and, further, that it is practicable to relieve these strains by repeatedly tapping the casting, thus permitting the individual metallic particles to rearrange themselves and assume a new condition of molecular equilibrium. The large number of tests made and the remarkable uniformity of the results obtained warrant me in making these statements with full confidence that the repetition of such experiments, even under less favourable conditions for accurate observation than I have enjoyed, will convince others of the correctness of my conclusions, and will perhaps establish a new law of the physics of cast iron.

A few practical deductions of universal application may be drawn from these observations. (1) Castings, such as hammer frames, housings for rolls, cast iron mortars or guns, which are to be subjected to severe blows or strains in actual use, should never be suddenly tested to anything approaching the severity of intended service. Quantitative tests made upon the impact machine prove that the molecules of cast iron rearrange themselves under reasonably few shocks, so that it is perfectly practicable to molecularly anneal such castings when cold. Pulleys, and indeed all castings, are subjected in every-day service to this process of molecular annealing; and old castings are therefore more reliable than new ones, unless they have been misused. It is not impossible that the same law applies to steel castings and perhaps to all metal castings, and that in testing new guns, each preliminary small charge of explosive material, subjecting the casting to comparatively moderate shocks, enables the gun to relieve itself of internal strains, and eventually to withstand with safety shocks which would have destroyed it without this precautionary measure. This, however, is mere theory, and must not carry the weight of the arguments regarding cast iron, which are clinched by a thousand actual tests. (2) Strong iron castings, and castings of irregular section, have greater initial strains than soft iron castings or castings of comparatively uniform section; and it is, therefore, more important to subject the former to gradually increasing shocks until the strains are relieved by the movement and re-arrangement of the molecules.

Tables.—The tables here given show the results of tests for transverse strength of test bars, of different section and widely different grades of iron, which have been subjected to this process of molecular annealing, and also tests made upon the impact machine with test bars cast in the same moulds. To avoid the unnecessary duplication of figures, a few individual tests only are here tabulated, but they represent the average of probably a thousand records. The largest apparent gain shown in Table I. in the transverse strength of companion bars of 1in. section, is 525 lb.—see last line of the table—or very nearly 19 per cent. It is evident, even without plotting all the tests, that they would show a gradually ascending curve having direct relation, first, to the character of the alloy of iron; and second, to the number of blows given, up to the point when strain is relieved—beyond which an increased number of blows does not increase the strength of the bar. Furthermore, it may be noted that these tests with the impact machine indicate the existence of a similar law with relation to the ability of the metal to resist sudden and severe shocks. Similar observations apply to the tests recorded of ½in. and 2in. bars. All the 2in. bars were broken upon the testing machine of Messrs. A. Whitney and Sons, by their operator, who was at first ignorant of the object of the tests. Subsequently, similar tests were made by that firm with their car-wheel iron, and identical results were obtained by them. The tabulated tests have been selected from the daily records of experiments made at the machine tool works of William Sellers and Co., Incorporated, Philadelphia.

In Table I., the left-hand columns show the breaking strain and deflection of test bars of different kinds of cast iron, cleaned in the ordinary manner with a wire brush. The right-hand columns show the tests of companion bars, cast from the same runner, molecularly annealed by being subjected to shocks in the tumbling barrel, or by tapping on one end with a light hammer, as noted under "Remarks;" also a few tests made with round bars 1⅛in. in diameter, cast on end.

Table II. gives a few of the tests with 1in. bars, made upon the new impact testing machine, using a 14 lb. weight. The tests marked A represent bars cleaned with a brush, and those marked B companion bars, molecularly annealed in the manner described.

Table III. gives a few records of 2in. test bars, broken by A. Whitney and Sons upon their machine. The tests marked A were cleaned with the brush; those marked B were molecularly annealed in the tumbling barrel.

Other experiments have suggested themselves in the course of this investigation; and my paper, therefore, is not presented as an exhaustive, but as a tentative treatment of this interesting and, I believe, novel line of research, which is not incapable, even in its present stage, of some practical application.

I have suggested, and adopted throughout this paper, the hypothesis of the mobility of the molecules of cast iron, resulting in an effect similar or analogous to the effect of annealing by heat, because it seems to be warranted by the facts developed by the experiments described; it is of course possible, in our *à priori* ignorance of the laws governing atoms and molecules, that the theory may not be correct, but the tentative propounding of a probable hypothesis, by inciting to a more extended course of experiment, along different related lines of investigation, often leads to establishing or disproving the theory, and thus adds to our stock of positive knowledge.

---

[*] Read at the Pittsburgh Meeting of the American Institute of Mining Engineers, February, 1896.

[†] In order to comprehend the modern idea of the nature of matter, we should try to realise that the molecules composing even the most dense solid substances with which we are familiar—such as gold, platinum, &c.—are not in contact, and are free to move within certain well defined limits. Lecture on "Matter," by the writer, *Journal Franklin Institute*, September, 1885, vol. xc., p. 184.

Guatemala: Central American Exhibition, 1897.—The Department of Science and Art has received, through the Foreign-office, a copy of a despatch from her Majesty's Acting Consul-General at Guatemala, respecting a "Central American Exhibition" of Science, Art, and Industry, which it is proposed to hold in that city next year, commencing on the 15th March, and closing on 15th July. Although primarily a Central American Exhibition, the Government of Guatemala are desirous that foreign nations should take part in it; a department will be assigned to them, and they will enjoy all the privileges possible, with the right of competing for the prizes.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Chief engineers: Mark Blakeman, to the Daphne, to date February 2nd; William J. Anderson, to the Skipjack, to date March 7th; and Henry Percival Vining, to the Vernon for the Seagull, to date March 13th, all reappointed on promotion; George Ramsay, to the Blanche, to date May 5th. Engineers: Harry R. Batchelor to the Magpie, additional, for re-commission; and Richard Bryan to the Wildfire, additional, for the Sans Pareil, to date April 17th; W. J. Duffell, to the Repulse, to date May 5th. Assistant engineer: Arthur F. White, to the Blanche, to date May 5th.

HODGES' COMPOUND BLOWER.

The accompanying illustration—Fig. 1—shows, by a transverse section, a compound blower manufactured by Messrs. Hodges and Co., of Cazenove-road, Stoke Newington, the special feature of which is that the air is subjected to several successive compressions during its passage through the machine, the number of which in the one under notice is three. A blower of this type is most generally used for giving a working pressure of 1½ lb. per square inch, but they are also made to give as high an air pressure as 4 lb., involving the necessity of six compressions. It will be seen from the sectional view that the blower is constructed with five separate blast wheels mounted on a common shaft, and enclosed by suitable casings, so formed as to allow each wheel to work in its own chamber. The shaft revolves in bearings carried by the brackets shown, and is driven by the pulley situated between the bearings. A A are the two outer blast-wheels, made of steel discs, with blades of the same material fixed on one side only; B B are two intermediate wheels of similar construction, but with narrower blades and consequently smaller capacity than A A; C C, the centre blast-wheel, has blades fitted on both sides of the disc, forming a double blast wheel, having still smaller blades with a consequent further diminished capacity. In the spaces D D D D, between the backs of the wheels and the adjacent casing, are provided a number of fixed radial scoops E, the peculiar shape of which, it is claimed, constitutes an important factor in the efficiency of the machine.

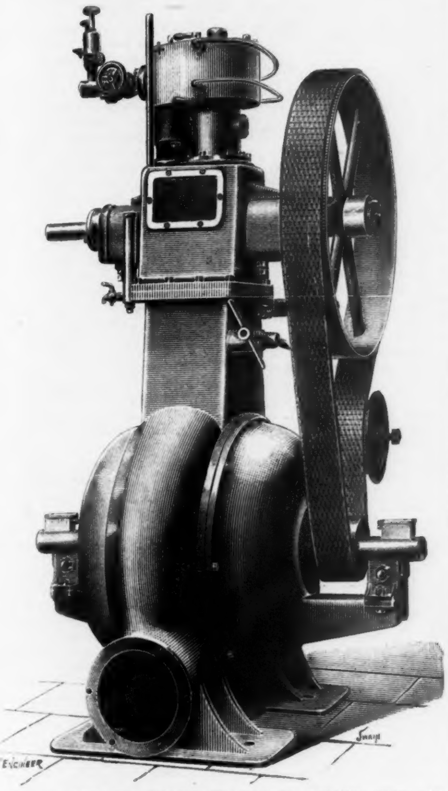

Fig. 3—HODGES' COMBINED ENGINE AND BLOWER

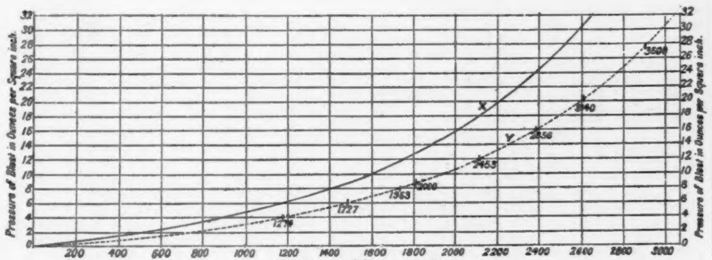

Fig. 2—DIAGRAM OF REVOLUTIONS AND AIR PRESSURE—HODGES' FAN

In operation, air entering the blower at either side, as shown by the arrows, is caused to rotate by the outer wheels A A, from the peripheries of which it is thrown off in a state of rapid rotary motion, the energy of which is utilised by impact upon the radial scoops E. This impact is said to transform the rotary movement of the air into a series of centripetal jets of high velocity, which, converging centrally, produces a blast at the inlets of the intermediate wheels of greater pressure than at the peripheries of the outer wheels, the increase in pressure being obtained without further expenditure of driving power. Upon the air leaving the outer wheels new conditions obtain, consequent upon its increased density and weight, and it may here be pointed out that a superabundance of air is always maintained under pressure at the inlets of the intermediate wheels, owing to the diminished area of the latter. A second compression now takes place by the agency of the wheels B, upon leaving which the air comes in contact with the second series of scoops and is finally compressed by the centre wheel and delivered into the annular receiving chamber F. Fig. 2 is a diagram giving the results of experiments made by Messrs. Hodges on the speeds and pressures of a compound blower of size No. 25, and shows clearly the pressure and volume of air delivered at any given speed. Referring to the diagram, each of the horizontal lines above O represents 2 oz. pressure per square inch, while each of the vertical lines from O to the right represents 200 revolutions per minute. The upper line X represents the curve of maximum pressures at the speeds given; thus at 1400 revolutions per minute the No. 25 size blower gives a maximum pressure of 8 oz. per inch, at 2600 revolutions 30½ oz. pressure. The most efficient working pressure is found to be about two-thirds the maximum, which is represented by the dotted line Y. On this line, at the pressures of 4 oz., 6 oz., 8 oz., 12 oz., 16 oz., 20 oz., and 28 oz., the figures under the intersections represent the cubic feet of air discharged per minute at the stated pressures.

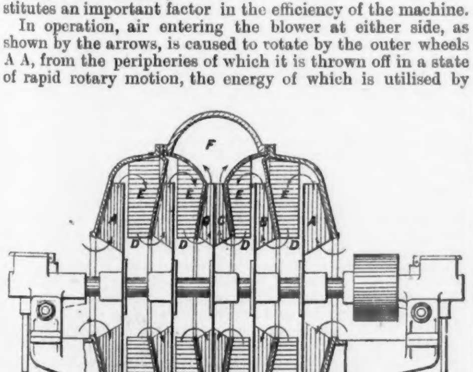

Fig. 1—HODGES' COMPOUND BLOWER—SECTION

We also illustrate in Fig. 3 one of these blowers combined with a high speed engine, the whole forming a compact and serviceable arrangement, obviating the use of counter-shafts and the loss of power incidental thereto. Being self-contained, the only fixing this machine requires is the bolting down and provision of steam and exhaust pipes for the engine. As the floor space required is limited, it can be placed in any suitable position, such as the corner of a smithy, close to the cupola, where the pressure of blast can be varied as required by the furnace attendant. When once the engine is started it requires little or no attention beyond the filling of the sight-feed lubricator, and a little oil being added to the crank chamber at weekly intervals. The connection between the blower and engine is made with an endless belt, a tightening drum or pulley being provided for keeping the belt taut. The engine, which is double-acting, is very carefully constructed, all the running parts being of steel, working in extra large phosphor bronze bearings. The crank chamber, it will be seen, together with the bearing brackets, is one solid casting, thus insuring perfect rigidity and alignment. The main bearings are adjustable upwards, by which means the shaft is retained square with the crosshead guide. The slide valve is of the balanced piston type, and the steam ports very short and straight. The cylinder, which is 8½in. in diameter, is fitted with relief valves and drain cocks, with pipes led into the exhaust and sight-feed lubricator. By extending the crank shaft, as shown, to receive a separate pulley, the engine can be used independently of the blower for driving any extraneous appliance or a line of shafting.

Although the engine is elevated it is remarkably free from vibration, even at very high speeds, a feature which is due to the careful method employed by the makers in balancing the moving parts. We have seen this engine running at a speed of over 500 revolutions per minute, driving the blower, and the engine running separately over 1200 revolutions without any holding-down bolts whatever, and with no perceptible vibration.

TESTING STEEL BOILER PLATES IN THE UNITED STATES.

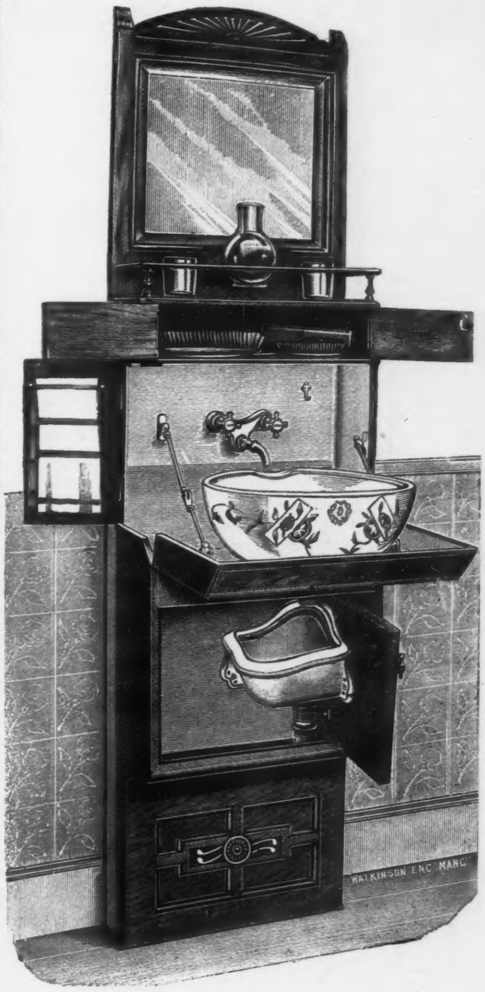
When the Board of Inspectors of Steam Vessels met at Washington, in annual session in January, the representatives of all the steel plate manufacturers in the country appeared, and urged a large number of changes in the regulations to ascertain the tensile strength. The Board, after considering the matter, acquiesced in some of the points urged, and adopted the following rule, which was made public at the Treasury Department on the 3rd inst.:—

"To ascertain the tensile strength and other qualities of steel plate, there shall be taken from each sheet to be used in shell or other parts of boiler which are subject to tensile strain, a test piece prepared in form according to a specified diagram. The straight part in the centre shall be 9in. in length and 1in. in width, marked with light prick punch marks at distances of 1in. apart, as shown, spaced so as to give 8in. in length. The sample must show, when tested, an elongation of at least 25 per cent. in a length of 2in., for thickness up to ¼in. inclusive; and in a length of 4in. for over ¼in. to 7-16in. inclusive; in a length of 8in. for 7-16in. to 1in. inclusive, and in a length of 6in. for all thickness over 1in. The reduction of area shall be the same as called for by the rule of the Board. No plate shall contain more than ·06 per cent. of phosphorus, and ·04 per cent. of sulphur, to be determined by analysis by the manufacturers, verified by them, and copy furnished the inspector for each order tested; which analysis shall, if deemed expedient by the supervising inspector-general, be verified by an outside test at the expense of the manufacturer of the plate.

"It being further provided that said manufacturer shall also furnish a certificate with each order of steel to be tested, stating the technical process by which said steel was manufactured. It being further provided, that steel manufactured by what is known as the Bessemer process shall not be allowed to be used in the construction of marine boilers. Plates over 1in. in thickness may be reduced to 1in. in the straight part for testing, in cases where the testing apparatus is not of sufficient capacity to test the full thickness of plate. The reduction of area and elongation must be equal to the requirement of full thickness of metal. Provided, however, that contracts for boilers for ocean-going steamers require a test of material in compliance with the British Board of Trade, British Lloyd's, or Bureau of Veritas rules for testing, the inspectors shall make the tests in compliance with the above rules. The samples shall also be capable of being bent to a curve of which the inner radius is not greater the 1½ times the thickness of the plates after having been heated uniformly to a low cherry red, and quenched in water of 82 deg. Fah."

RAILWAY CARRIAGE LAVATORIES.

The modern luxuries of railway travelling, and the extensive introduction during recent years of sumptuously equipped saloons on most of the leading lines, have necessitated special attention to matters of detail connected with the general fittings and accessories of these carriages. With regard to the sanitary fittings, Messrs. Morrison and Ingram, of Manchester, have recently designed several specially arranged lavatories and closets for railway carriages, of one of which we give an illustration showing a closing-up lavatory, which, whilst being commodious and replete with convenient accessories, is compressed into a remarkably small space, the lavatory, when closed, not projecting more than 9¾in. from the wall, whilst the width is only 19½in., and the height 6ft., including the over-mirror. The lavatory, every working part of which is readily accessible, is fitted with a hot and codl water supply to the basin, and a convenient arrangement is provided for hanging towels, whilst there is also a small cupboard suitable for various toilet requirements. The folding urinal in connection with the combined arrangement is automatically flushed, whilst the door is kept open.



WALKINSON ENG. MANC.

WEAR OF TIRES ON PASSENGER ENGINES OF THE NEW YORK CENTRAL RAILWAY FOR THE PAST TWENTY YEARS.

By P. H. Dudley.

Comparing the weights upon the drivers a few years ago with those in present use shows an increase in the static or dead load of some 65 per cent., while the increased speed of the trains now produces dynamic effects more than double the static loads, yet by increasing the width of the head of the rails as they were renewed and the higher standard of track maintained, the rate of the wear of tires for the heavier locomotives has not increased, but, on the contrary, decreased. In 1883, on the 65 lb. rails, deep and narrow type of heads, drivers carrying 13,360 lb. ran an average of 19,400 miles for a loss of $\frac{1}{16}$in. in thickness of the tires. This was the second type of 65 lb. rails, the first one having been rolled in England and had a wider head.

In 1884 the 5in. pioneer 80 lb. rail was put in service, the head being $2\frac{11}{16}$in. wide. Its use was yearly extended, and by 1889 locomotives on the Hudson division made nearly one-half their mileage on the 80 lb. rails. Engines then carrying 17,600 lb. per driver ran an average of 19,300 miles per loss of $\frac{1}{16}$in. in thickness of tire. In 1891 passenger engines on the Hudson division made their entire mileage on the 80 lb. rails, while those on the Mohawk and Western divisions made about three-quarters of theirs on the same class of rails; drivers carrying 20,000 lb. ran an average of 19,400 miles per loss of $\frac{1}{16}$in. in thickness of the tire. This refers to the loss by wear and returning for future service. In 1892 the 100 lb. rail, head 3in. wide, was laid on the Harlem line, which carries the combined passenger traffic of the three railroads entering and leaving Grand Central Station, New York City. The renewing of the entire line of the New York Central and Hudson River Railroad from Mott Haven Junction to Buffalo and return with 80 lb. rail was completed in 1892. In 1894 the 100 lb. rail was laid from Spuyten Duyvil to Peekskill, making about one-quarter of the Hudson division laid with 100 lb. rails.

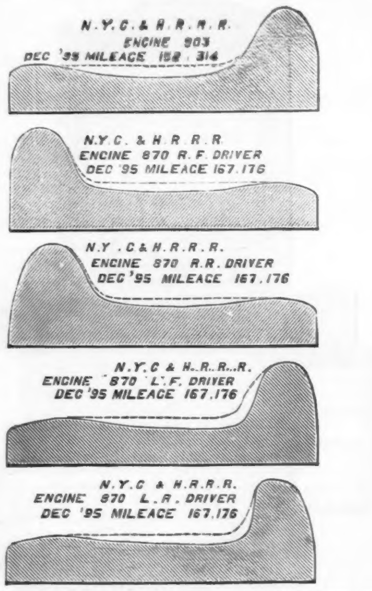
In June, 1895, I asked Mr. William Buchanan, general superintendent of motive power and rolling stock, for the mileage of some of the class "I" engines running over the 80 lb. and 100 lb. rails. When the class "I" engine was designed in 1889, the weight on each driver was 20,000 lb., but as the 80 lb. rails were put into the track the weights have been increased to 22,000 lb. The total weight of the locomotives in running service is 200,000 lb., or over 40,000 lb. being upon the truck. The mileage of the tires only includes one turning since October, 1892, and ends March, 1895.

Some of the engines, of which there were 43 in all, did not enter service until 1893, and others in 1894.

The list is so large, covering such a wide range of service, that it must show conclusively whether or not a broad flat-topped rail increases or decreases the rate of wear of tires running over them. The 43 engines ran 3,706,567 miles, and the total loss in thickness of tires in sixteenths of an inch was 160, or an average of 23,166 miles for a loss of each $\frac{1}{16}$in. of tire. Twenty-three of the engines which ran in part over the 100 lb. rails show an average mileage of 29,046 miles for each $\frac{1}{16}$in. loss in thickness of the tire. The mileage of 19,400 miles per loss of $\frac{1}{16}$in. in thickness shown by the light engines on the 65 lb. rails is now much exceeded by the heavier engines on the 80 lb. rails, the average mileage being 23,166 miles, and on the 100 lb. rails it will exceed the 29,046 miles, which over one-half the present engines now show by only making a part of their mileage on the wide rails.

The comparison between the wear of tires on the engines running the Empire State Express over the Hudson division, making one-fourth of the mileage on the 100 lb. rails, and the one running over the Western division exclusively on 80 lb. rails is very interesting.

The engravings show the approximate wear as obtained by plaster casts after the mileage indicated on them had been made by the engines.



Diagrams Showing Wear of Tires on Engines No. 903 and No. 870.

Engine 870 commenced the service for which the wear of the tires is shown May 25th, 1894, and completed it December 21st, 1895. The engines are double crewed, as is customary with all, and the mileage made per month fluctuated between 8576 and 9200. Out of the 575 days the engine was worked 571 days, the four idle days being occupied in boiler washing. The total mileage in that period was 167,176 miles. During all this time the fires were not drawn except on the four idle days.

The following table shows the wear of tires with different weights on them and running on various rail sections:—

No. of engine.	No. of miles run.	Circumference of drivers in feet.	Pounds of metal lost per 1000 miles, four-drivers.	Rail section on which engines ran.	Weight on each driver. lb.
870	167,176	20·41	0·801	80 lb. and 100 lb.	20,000 to 22,000.
903	152,314	22·00	1·332	80 lb. rails.	20,000 to 22,000.
84	56,219	18·06	1·234	English 65 lb. rail.	15,000 to 18,000.
86	73,647	18·06	1·887	,, ,, ,,	15,000 to 18,000.
4	78,864	17·28	1·379	,, ,, ,,	15,000 to 18,000.

NOTE.—The 100 lb. rail has a head 3in. wide, the 80 lb. rail a head $2\frac{11}{16}$in. wide, and the English 65 lb. rail had a head $2\frac{3}{8}$in. wide.

The loss per yard in circumference of tire, per 1,000,000 tons rolling contact on the rails was as follows:—

	lb.
No. 870	0·042
No. 903	0·070
No. 84	0·121
No. 86	0·136
No. 4	0·132

The general dimensions of the class "I" engines are given in the following table:—

Cylinder, diameter and stroke	19in. × 24in.
Steam port	18in. × $1\frac{1}{4}$in.
Exhaust port	18in. × $2\frac{3}{4}$in.
Bridges	$1\frac{3}{8}$in. wide
Valves:—	
Travel	$5\frac{1}{4}$in.
Outside lap	1in.
Inside lap	None
Boiler:—	
Diameter, smallest ring	58in.
Pressure per square inch	170 lb.
Fire-box:—	
Length, outside	$105\frac{1}{2}$in.
Width	$40\frac{3}{4}$in.
Area	27·3 square feet
Heating surface	150·8 square feet
Flues:—	
Number	268
Outside diameter	2in.
Length between sheets	11ft. 11in.
Heating surface	1670·7 square feet
Total heating surface	1821·5 ,, ,,
Weight of engine in working order	120,000 lb.
Weight on drivers	80,000 lb.
Weight on trucks	40,000 lb.
Weight, maximum tender loaded	80,000 lb.
Tractive force per pound M. E. P.	111·07
Adhesion to tractive force	0·20
Diameter of drivers	78in.
Driving wheel base	8ft. 6in.
Total wheel base of engine	22ft. 9in.

Engine No. 903 hauled the "Empire State Express" on the western division from April 3rd, 1894, to December 3rd, 1895, total mileage 152,314. Of the four tires of engine No. 870, the left front one was physically the softest and shows the most wear, as seen in the accompanying illustrations. Both front drivers show increased wear over the rear ones from crushing the sand when first applied to the rails, and is more noticeable than on the crucible steel tires of the lighter engines, of which I took plaster casts many years since. Ross Meehan shoes were applied to the drivers covering the full tread and flange of all drivers for both engines. On No. 870 considerable wear was produced on the outside of the flanges of the left side drivers, which is not included, as it was not produced by the rails.

The wear of tires per 1,000,000 tons rolling contact on the rails for the amount of metal lost, as shown by plaster casts, would be influenced by many conditions which need not be considered here; yet the results point to the same general fact that by widening the top of the rail, and giving it a larger top radius, the rate is decreased, notwithstanding an increased weight is carried upon the drivers. The top radius of the pioneer 80 lb. rail is 12in., with $\frac{5}{16}$in. corner radii, and for the 80 lb. and 100 lb. rails, laid in 1892 and since, it is 14in., and corner radii of $\frac{5}{16}$in. The important point is to secure as large an area of contact between the drivers and the rails as practicable, for the larger the area is the less are the wheel pressures per square inch of contact, and the greater width of metal of both rails and wheels to resist and distribute the tractive force exerted. The tractive force of both 870 and 903 on the rails drawing the same train would be practically alike, and the difference in wear of tires mainly due to the greater average area of contact of 870, running part of its distance on the 100 lb. rails, while 903 ran entirely on 80 lb. rails. The mileage of either engine is very large, nearly double what is obtained on the narrow-headed rails, as will be seen by a comparison with engines Nos. 84, 86, and 4, which ran on the 65 lb. rails. The practical results of introducing the broad-topped stiff rails show a decreased wear of tires, frogs, rails, ties, and expense of minimum maintenance, while the speed and train loads have been largely increased. The standard freight train load of the New York Central and Hudson River Railroad, on the 80 lb. rails, is 50 loaded 60,000 lb. capacity cars, making a gross load of 2250 tons, forming a train 2000ft. long, which runs 150 miles in six to eight hours. The train load has more than doubled from the old 65 lb. rails.

The broad thin type of head is making rapid progress abroad. Dr. Haarman, at his Osnabruck works, Germany, has introduced several sections, while many are being rolled in England for India and Australia. My 80 lb. section has recently been rolled in England for two Canadian lines. While the thin wide head and stiff type of rails is now generally recognised as the most economical form, the pioneer 5in. 80 lb. rail met with decided opposition, as being heavier and stiffer than was needed. Its introduction was largely due to the persistent efforts of Mr. J. M. Toucey, then general superintendent, but now general manager, of the New York Central and Hudson River Railroad. The rail once in the track made friends and had strong advocates, for the value of stiffness in a section was recognised, the principle being utilised by many railroads. It is not weight alone, but stiffness as well, which gives value to a section. It marked an epoch in railway progress, and while the advantages of a broad head and stiff 5in. rail have exceeded expectations, there are still greater values to be obtained by the use of the broader head and stiffer 100 lb. rail.—*American Engineer Car Builder.*

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. Steam coal shipments are good, with fair inquiries for the future. Prices steady. The house coal trade continues good for the advancing season, and prices are without change. Tin-plates in better demand. The steel and iron works continue well employed.

Prices:—Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s.; colliery small, 4s. 3d. to 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s.; hematite warrants, 47s. 9d., f.o.b. Cumberland; Middlesbrough No. 3, 37s. 10d. prompt; Middlesbrough hematite, 45s. 4d. Iron ore: Rubio, 11s. 9d. to 12s.; Tafna, 11s. 3d. Steel rails, heavy sections, £4 12s. 6d.; light ditto, £5 to £5 5s., f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d., all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel coke, 9s.; Siemens coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C., 18s. 6d. to 20s. Pitwood, 15s. 3d. to 15s. 6d. London Exchange telegram: Copper, £44 17s. 6d.; Straits tin, £59 10s. Freights: Homeward, firm.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

STEEL is steady this week at £5 for Siemens marked steel slabs at stations in the Midlands, £4 15s. for Bessemer blooms and billets, £6 to £6 10s. for Siemens bars, £5 7s. 6d. to £6 for Bessemer bars, £7 to £8 10s., according to tests and sizes, for Siemens best boiler-plates, and £5 15s. delivered for Bessemer ship-plates. Angles and girders of basic steel are £5 10s., and £6 5s. for boiler-plates. All the steel works are active, and the finished iron works and blast furnaces are also well engaged upon orders booked at the commencement of the new quarter.

Common bars are £5 5s. to £5 10s.; merchant bars, £6 to £6 5s.; and marked iron £7, with £7 12s. 6d. for the L.W.R.O. brand of the Earl of Dudley's make. Black sheets are £6 12s. 6d. to £7 for singles, £7 to £7 7s. 6d. for doubles, and £7 15s. for lattens. Angles are £5 15s., stamping sheets are £9 10s. and best thin sheets £11. Nail rod is £6 10s. Hoop and thin strip £6 7s. 6d. Tube strip for bedstead tube making is £6 5s., and for gas tube making £5 10s.

Staffordshire cinder pig is 36s. to 37s. for forge, with 2s. more for foundry; part mine, 39s. to 45s., according to quality; and all mine 55s. to 57s. 6d. Cold blast pig is 90s. Lincolnshire forge pig is 44s. 7d. net at stations. North Staffordshire and Derbyshire, 42s. to 43s., and Northamptonshire 41s.

The Tame and Rea District Drainage Board, at their quarterly meeting on Tuesday, had before them the estimates for the ensuing year, totalling £60,170. The Board approved a scheme submitted by their engineer, Mr. Till, for a large extension of the sewage farm. This scheme of extension will in all probability ultimately involve a capital expenditure of £244,500. When the Board was formed in 1877 the population in the drainage area was but 481,944. In 1884 the constituency had increased to a population of 605,594, and, without any extension of the area, it is estimated that by the year 1912 its population will amount to 900,000 persons, nearly the whole of whom will be resident on land draining to the sewage farm. A considerable extension of land and works is therefore absolutely necessary in the course of the next few years, in order to deal with the continually increasing quantity of sewage. Parliamentary powers will be necessary. The engineer of the Board is Mr. Till, and the services of Mr. Charles Hawksley have also been retained on a commission of 5 per cent. on the cost of construction, Mr. Hawksley undertaking to design the works, prepare all needful working drawings, and supervise the works during construction, as well as to give advice in relation to Local Government Boards and Parliamentary inquiries, and attend thereat. The new land which is to be acquired will raise the total area of the farm to be used for sewage disposal to 2320 acres, of which over 2000 acres will be available for irrigation. Mr. Till estimates the costs of the works only, including main conduit, outfalls, and stream diversions, new improvement, pipes and main drainage, laying out, machinery, and raising mains, extension of existing buildings, &c. &c., and stocking the land, at £124,500, exclusive of easements, compensation, or purchase of mill or water rights. He estimates, approximately, the cost of pumping expenses for lifting 5,000,000 gallons of sewage per day to the high level lands, exclusive of interest, sinking fund, or capital, at about £900 per annum.

Cycle engineers seem to be enjoying a good time. Easter week was one of the most remarkable in the history of the cycle engineering trade, and orders continue to pour into the Midland towns for machines from all parts of England and abroad, and factory accommodation at Coventry is extending in all directions. This remarkable activity in the cycle and cycle fittings trades is responsible for some extraordinary advances in the cycle share market of the Midlands, in which securities of this description have lately been sought after, to the neglect of nearly all other kinds of industrial shares. The extent of the upward movement may be best gauged, perhaps, by a comparison of the prices of a week ago with those realised on the first of the month, before the "boom" had set in. Beeston Pneumatic Tire at the earlier date were selling at from 18s. to 20s.; within the past ten days the price realised has been £6. W. Bown, Pref. 7 per cent., has risen in the same period from £3 15s. to £4 10s.; Cycle Components, from 20s. to 44s. 6d.; Humber and Co., from 26s. 3d. to 29s. 3d.; Pneumatic Tire, from £9 to £12 15s., ex dividend; Rudge-Whitworth, from 13s. 9d. sellers to 19s. 6d. buyers; St. George's Engineering, from 21s. to 35s.; Allday and Onions, from £4¼ to £5¼; and Self-sealing Air Chamber, from 15s. to 21s. The steel tube concerns which minister to the wants of cycle manufacturers have shared in the advance, Star Tube rising from £3 premium to £4 premium, or £5 for the £1 shares, and Rose Tube from about par to £1 premium; and during the week, in some of these cases, still further advances have been made. The newly-formed Cycle Manufacturers' Tube Company have arranged for the erection of a factory upon land purchased from the Coventry Corporation. The contract for the first portion of the work amounts to £21,000.

A conference of representatives from the County Councils of Montgomeryshire, Breconshire, Radnorshire, Cardiganshire, Merionethshire, and Carnarvonshire, with the local members of Parliament and gentlemen interested in agriculture, has taken place at Machynlleth. The object of the meeting, which was promoted by the directors of the Cambrian Railway Company, was to discuss methods for facilitating the carriage of agricultural produce over the district served by the Cambrian Railway. Sir Humphreys Owen, M.P., presided, and among other directors present were Lord Henry Vane Tempest and Mr. Edward Davies. After an interesting discussion of the conveyance of live stock, the chairman announced, amidst applause, that the company was prepared to revert to the rates of 1892 locally. Mr. Forrester Addie advocated the opening of a market in the Black Country by a reduction in the rates for produce, and the publication by the company of a list of customers and producers. Professor Parry, Aberystwith, spoke of unfavourable rates for home produce compared with foreign goods.

Three fatalities have unfortunately occurred at Himley Colliery, causing the death of William Marson (20), Gornalwood, who was killed whilst following his employment at No. 8 pit, Himley Colliery; and the death also of a man named Joseph Shaw (51), who resided at Pensnett; and of Wallace Kennell (22), of Wallheath, who was killed on the Earl of Dudley's private railway at Himley Colliery. The first two cases were caused by the fall of a roof whilst they were fixing up an iron girder across the roof. In the last-named case the deceased was engaged in shunting, when he was crushed against a truck and died almost immediately. Verdicts of accidental death have been returned.

The Public Works Committee of the Birmingham City Council have decided to report to the Council in favour of the scheme of reorganisation of the work of the City Surveyor's Department recently mentioned. It is proposed to continue the services of Mr. Till in connection with the City Council, but not in connection with the Drainage Board, and to pay him a reduced salary of £600 a year; while a deputy or assistant colleague shall receive £400 from the Corporation and £400 from the Drainage Board. This arrangement will involve no increase of costs, Mr. Till's salary hitherto having been £1000 from the City Council, and £400 from the Drainage Board.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—Although there is perhaps not quite so confident a tone in some quarters, owing to the persistent slackening off in the demand during the last month, with a consequent weakening of prices for raw material, there would seem to be nothing actually in the present position to occasion any real uneasiness as to the future. It was not to be expected that the heavy buying that went on two or three months back could be continued; and apart from the lull which was only natural to follow, trade, taking it all through, is satisfactory, and the principal iron-using branches of industry are not only kept fully employed, but in most departments new work comes forward rather in increasing than decreasing quantities. Of course there are nervous or needy holders of iron who are always, in a condition of the market like the present, anxious to realise even at a sacrifice in price. Generally, however, a strong tone is maintained; and apart from second-hand parcels or speculative transactions, prices have not, under the circumstances, given way more than might have been looked for.

A continued absence of animation is the report throughout the iron market here, and although there was an average attendance on Tuesday's Exchange, business all through was extremely slow. In pig iron especially there is a complete pause as regards further buying for the present. This absence of new business coming forward has, however, not hitherto been regarded as appreciably affecting the position of makers, and the report on 'Change of the altogether unexpected action of the associated Lincolnshire smelters at their meeting last Friday in deciding to reduce their list rates 1s. per ton occasioned considerable surprise. It was generally supposed that the Lincolnshire makers were so heavily sold that they were practically independent of new business for some time to come, and the explanation is that Northampton pigs have recently been offered at such extremely low figures that the important Staffordshire trade in Lincolnshire pig iron has been almost, if not altogether, lost, and that it is solely with a view to the recovery of this trade that the reduction has been made. With regard to other brands of pig iron, makers' prices remain without quotable change, but the position, taking it all through, is unquestionably weaker, and in the open market prices were very irregular, merchants, in fact, making their own quotations, according to circumstances. Lincolnshire iron, at the reduced rates, is now quoted 41s. for forge to 43s. for foundry, with Derbyshire remaining at 46s. to 47s. for foundry, net cash, delivered here, but with regard to Derbyshire iron the position of makers is not so strong as it has been recently. Local makers have made no change in their quoted prices, foundry qualities remaining at 46s. 6d., less 2½d., delivered here, and it is only where they come into competition with forge Lincolnshire at Warrington that they will be at all affected by the reduced rates. For delivery Warrington, 41s. 8d. net cash is now about the average price for Lincolnshire forge, and Lancashire makers, to secure business, will have to come in at something like the same figure. Makers' prices for outside brands are somewhat easier, but without quotable alteration. They are still quoting 47s. net cash for good foundry Middlesbrough, delivered by rail Manchester, but orders could be placed at 6d. to 9d. less, and delivered Dock Quays, Manchester, at about 44s. 9d. net cash. For Glengarnock makers' official quotations are 48s. 6d. delivered Lancashire ports, and 50s. 6d. delivered Manchester Docks, but sellers could be found at 6d. to 9d. under these figures, and Eglinton could be bought without difficulty at 47s. net prompt cash, delivered Lancashire ports, and 49s. 3d. delivered Dock Quays, Manchester.

New business comes forward steadily in the manufactured iron trade, and forges are kept fully going. For bars prices are firm at last week's quotations, £5 10s. to £5 12s. 6d. being the minimum for Lancashire, and £5 12s. 6d. to £5 15s. for North Staffordshire qualities, delivered here. Sheets, however, are weak and irregular, owing chiefly to the collapse of prices in Staffordshire; and £7 5s. to £7 10s. may perhaps be taken as about the average figures for delivery here. The Association list rates for hoops are steady at £6 2s. 6d. for random, to £6 7s. 6d. for special cut lengths, delivered Manchester district, and 2s. 6d. less for shipment.

In the steel trade a moderate business is reported, with a steady tone in prices at late quotations, makers being very firm at 58s. to 58s. 6d, less 2½, for good foundry hematites; with £4 7s. 6d. to £4 10s. net cash the average figures for steel billets; £6 to £6 2s. 6d. for local made steel bars; £6 7s. 6d. for boiler plates; and £5 10s. to £5 12s. 6d. for steel girders, delivered Manchester district.

A brisk tone prevails in the metal market, with prices well maintained at full list rates.

In the engineering trade general activity continues to be reported, and in some quarters a considerable amount of new work has been booked during the last few weeks. This remark applies particularly to machine tool makers, who have secured some large orders for delivery well into next year, whilst at many of the local establishments there is quite a pressure to get through the work already in hand. Stationary engine builders also continue fully engaged, both in the light and heavy departments; boiler makers are also kept extremely busy, having a larger weight of orders in hand than they have had for a considerable time past, and amongst locomotive builders a fair amount of new work has also been secured.

Messrs. Henry Wallwork and Co. have just completed for Messrs. A. C. Wells and Co., of Manchester and London, a specially designed painting machine to be used on the Liverpool Overhead Railway. This consists of a modification of their "Lightning" painter, which was some time back described and illustrated in THE ENGINEER, but in the present instance it is to be driven by an electric motor. The whole of the machinery, consisting of the electrically-driven air compressor, by which the paint is forced up to the painting nozzles, and then discharged in fine spray, the paint receptacle, and the electric motor, are fixed, in compact form, upon a travelling car constructed to run upon the tram rails below the overhead railway, and the machine can be operated at any point along the line by an electric current supplied from the company's own installation. Another improvement and modification of their painting machinery is also being introduced in the form of a portable self-contained painting machine weighing less than 1 cwt., and complete in itself, with air-pumps, paint receivers, and all the requisite apparatus carried on one small base-plate, fitted with wheels and a couple of handles, arranged in truck form, so that it can be readily wheeled from point to point. The mixing arrangement, which is automatic, is operated by the rotation of the crank actuating the air pump, which is worked by hand, and supplies the compressed air for forcing the paint to the nozzles. I may add that the method of painting by machinery, introduced by Messrs. A. C. Wells and Co., is making considerable headway, the machines they have already supplied having, I understand, given great satisfaction, and I hope, for a later issue, to be in possession of more complete details, with illustrations, of the newly designed and improved machines they are now introducing.

Throughout the coal trade the position remains unsatisfactory, with comparatively few collieries working above four days per week, and all descriptions of round coal hanging upon the market. With the present mild spring weather, requirements for house fire qualities are necessarily falling off, and although there is no actually quotable change in list rates, surplus supplies are pushed for sale, and in the open market prices are weaker. The lower descriptions do not move off any better for iron making, steam, and general manufacturing purposes, and the complaint generally is that they are extremely difficult to sell, with only excessively low prices obtainable, ordinary steam and forge coals not averaging above 5s. 9d. to 6s. 3d. at the pit mouth. For engine classes of fuel there is a fair demand, and with collieries in many cases rather short of supplies, the tendency as regards prices is, here and there, decidedly in an upward direction. The general average prices, however, remain unchanged at about 3s. and 3s. 6d. for common, to 4s. and 4s. 6d. for better qualities, and 5s. for special sorts, at the pit mouth, and although in a few cases advances of 3d. per ton are being got, these are altogether exceptional.

In the shipping trade business shows no improvement, and owing to the excessively low figures at which orders recently have only been obtainable, some of the collieries are declining to compete at all for business, preferring rather to leave this branch of trade alone than to accept orders at altogether unremunerative prices. Common steam coals, delivered Garston Docks or High Level, Liverpool, average about 7s. to 7s. 3d., and for delivery Partington tips, Manchester Ship Canal, about the same figures would be taken.

Some feeling of anxiety with regard to the possibility of another wages dispute in the coal trade is beginning to manifest itself as the period approaches when the present Conciliation Board agreement comes to an end. It is evident that the miners are as determined as ever upon the question of a minimum wage, and this part of their policy they have all along kept to the front with unshaken persistency. The coalowners, on the other hand, are as strongly adverse to binding themselves down to a fixed minimum rate of wages—at any rate on the basis proposed by the miners—and if the question is to be fought out on this issue, it is difficult to see how a renewal of the struggle can be avoided. By the agreement which comes to an end in July, the miners have already succeeded in getting in the thin end of the wedge with regard to the principle of a minimum wage, and it is probable they may endeavour to drive it still further home by suggesting that the existing arrangement — that is, that the present rate of wages remain undisturbed for a period of eighteen months, after which the colliers, if the state of trade warrants it, are to be in a position to ask for an advance—shall be carried over for another similar period. The contention of the coalowners, however, is that the present state of trade and the lower wages paid in other competing colliery districts does not warrant the rate of pay already received by the federated miners, and that the Board of Conciliation shall have power to regulate the rate of wages, which, of course, means that there must be some reduction. I scarcely think, however, that either the miners or the coalowners will care to enter upon another protracted contest, and in well-informed quarters it is thought probable that some means will be found to bridge over the difficulty by an arrangement which, whilst not actually binding the coalowners to a minimum wage, may for the time being satisfy the miners, who will no doubt be advised by their leaders that it is not their policy just at present to push the matter to the extremity of forcing on another struggle. It would seem, however, to be almost inevitable that the minimum wage question, which has taken so strong a hold upon the minds of the colliers, must sooner or later be fought out, but in all probability the miners' leaders will prefer to wait until the condition of the coal trade is more favourable than it is at present for carrying the struggle to a successful issue.

Barrow.—The demand for hematite qualities of pig iron is still brisk, and orders are offering freely to makers, who are already well sold forward. Business in Bessemer qualities of metal is not only strong by reason of the immediate large consumption on the part of steel makers, but because there is an all-round good demand for forward deliveries generally. The production of the 39 furnaces in blast is all going into consumption, and during the week 1102 tons have been cleared out of warrant stock, leaving 302,816 tons still in hand, or 13,641 tons increase since the beginning of the year. Makers quote their old rates of 50s. per ton for parcels of mixed Bessemer numbers, net f.o.b., and warrant iron is selling at 47s. 11d. net cash, while buyers are offering at 47s. 10½d.

There is still a good business in the iron ore trade, and smelters are using large supplies as well of native as of Spanish qualities. Last week's quotations are still maintained.

The steel trade is brisk, and the mills are busy in every department, including rails and plates, as well as billets, hoops, castings, and merchant steel. Orders are still numerous all round, and prices are firm, heavy rails being at £4 12s. 6d. per ton.

Shipbuilders are looking forward to some new orders, and during the week the Naval Construction and Armaments Company has booked an order from the Admiralty for two more torpedo boat destroyers. It has already in hand two of this class of boat, and it is quite on the cards that boats of a higher rate of speed will be ordered.

The coal and coke trades are very firm.

In shipping things are much brisker. During the week the exports from West Coast ports reached 9189 tons of pig iron and 14,694 tons of steel, as compared with 4098 tons of pig iron and 4559 tons of steel in the corresponding week of last year, an increase of 5091 tons of pig iron and 10,135 tons of steel. Since the beginning of the year the shipments have totalled up to 94,771 tons of pig iron and 131,222 tons of steel, as compared with 78,888 tons of pig iron and 110,169 tons of steel in the corresponding period of last year, an increase of 15,883 tons of pig iron and 21,053 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

BETTER time has been worked in most of the collieries in the South Yorkshire district. The week's output has been an average one. Very little change has taken place in the condition of trade. Values remain low, although the prices of steam and small fuel have an upward tendency. Slack and smudge are in increased request, owing mainly to the extra demand for coke-making purposes. Establishments making their own coke find it to their advantage to use their own slack and smudge. The supply of slack is very restricted owing to the short time worked at the pits. A limited tonnage of both Silkstone and Barnsley house coal is being forwarded to London, owing to the mild weather, and the large quantity of seaborne coal at present in the market. A similar remark applies to the eastern and other markets.

In house fuel the quotations, owing to the plentiful supplies, are low. Silkstone coal is at 8s. to 9s. for best hand-picked, while ordinary samples are obtainable at 7s. to 7s. 6d. per ton at the pits. Best qualities of Barnsley "softs" make from 7s. 3d. to 7s. 6d. per ton, inferior qualities 6d. to 9d. per ton less. Owing to the low prices asked for secondary sorts of thick seam coal, the thin seam pits are worked with considerable difficulty. The best qualities of this class will not fetch more than 5s. 9d. to 6s. per ton. There is an abundant supply of fuel in the market, and low values only can be obtained. It is expected in many quarters that the Baltic ports will shortly be opened. A large tonnage is being forwarded in connection with railway and other contracts. Steam coal prices range from 6s. 9d. to 7s. per ton. Good screened slack is obtainable at from 3s. 6d. to 4s.; ordinary pit slack, 2s. 6d. to 2s.; while smudge is as low as 1s. 6d. per ton at the pits. An improvement has taken place in the coke trade, and the majority of the district ovens are now well employed. North Lincolnshire has been taking a much larger tonnage of late, owing to more furnaces being put into blast. Derbyshire is requiring an average amount, and a similar remark applies to several of the other iron smelting districts. Values of best coke range from 9s. 6d. to 10s. per ton in owner's wagons at the works.

The heavy departments of the city continue in the same regular condition. The railway material branchs are well off for work. Some very good orders for springs, buffers, axles, tires, and similar goods, have recently been booked. These have been mainly for the Midland, and the Manchester, Sheffield, and Lincolnshire, for its London extension, as well as for other of the leading home railway companies. Several foreign railways, including South American, have also placed some large contracts. The increased activity in these branches has had a stimulating effect on the demand for steel, and three of the Bessemer works are working night and day. The Queensland Government have placed an order for half-a-dozen engines with the Yorkshire Engine Company. This company is also well employed on work in other departments. The armour-plate mills and forging presses are busily engaged on Government orders, and it is satisfactory to note that during the last week or two some further orders for shells of various patterns have been received by the Sheffield firms who make this class of work a speciality.

In the lighter industries a remarkable improvement has taken place since the quarter ended. A very brisk business is being done in files, the men working full time. Competition is still very keen, and it is stated that in some cases manufacturers are disposing of the files at cost prices, relying on the steel used for their profit. The skate business has been very poor this year, owing to the absence of any prolonged winter, and heavy stocks laid in last year have remained untouched. The mild weather has had the effect of stimulating the demand for building tools, and heavy tools for the engineering trades have been in good request. The saw business is only quiet. Since Easter an improvement has taken place in the cutlery trade. Some excellent orders have been received for cutlery. These have been mainly for the pen and pocket qualities. A very good business is also doing in the table knife branch. Manufacturers of the cheaper qualities of cutlery are well off for work, finding full employment for their men.

Lord Charles Beresford, who has been the guest of the Master Cutler—Mr. H. Herbert Andrew—during his visit to the Sheffield Press Club, visited the Toledo Steel Works, the Master Cutler's establishment, and the Cyclops Works, Messrs. Charles Cammell and Co., on Monday. At the first place he witnessed the process of manufacturing tool steel, cotton spindle steel, and steel for mining purposes; as well as the production of special steel for safes, the preparation of metal for projectiles, the Siemens-Martin process, the drawing of telegraph wire, &c. The Master Cutler and Mr. J. L. Potts, the manager, conducted Lord Charles Beresford and the party accompanying him over the departments. At the Cyclops Works, Mr. Alexander Wilson, J.P., the managing director, and Mr. T. W. Jeffcock, J.P., one of the directors, received the visitors, who were shown the rolling of a 25-ton armour plate for H.M.S. Illustrious, now being built at Chatham. Another plate for the Victorious was Harveyised, and his lordship was also able to see the machining of the plates to be used in one of the new warships, as well as several of the minor processes. At the Press Club, Lord Charles vigorously criticised the naval system at the Admiralty as theoretically excellent but practically rotten. He particularly objected to no provision being made for manning the new war vessels, pointing out that the First Lord of the Admiralty admitted that in April next he would be 11,000 men short, and that he intended to take them from the First Naval Reserve. His lordship contended that we had no Naval Reserve, and that 22,000 more men will be required a year hence. He wants to know where the First Lord is going to get them.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THOUGH the local iron market is very quiet, and both buyers and sellers show a disinclination to operate at present, yet the tone cannot by any means be described as depressed. On the contrary, business men are decidedly hopeful, for their belief is that this lull is simply one of those unaccountable pauses which occur from time to time in every upward movement, when buyers, after a brisk period of buying, take a rest. Makers have certainly well filled order books, and are quite indifferent about selling further at present, while buyers have ordered enough to satisfy their requirements for some little time to come, and they hold off just now. But there is nothing in the position and prospects of trade to favour an opinion that trade is falling off.

The activity in the pig iron industry is unprecedented, the production is the largest on record for the North of England, and it is regarded as certain that it is not now in excess of the requirements, though it has been so for the last half-year. But now the exports are very heavy, and local consumption has never been larger, for finished iron and steel works are in full swing—indeed, the present rate of production has never been surpassed. It is calculated that at the end of the month a decrease of 3000 tons in the stocks of Cleveland pig iron will be reported. Some apprehension is felt that the output of pig iron will be increased, and that too many furnaces will be put in blast. This has been partly caused by the report of the sale of the Coultham Ironworks, but it is not likely that they will enter upon the competition for at least six months, as the furnaces need to be relined. It is not probable that the new owners will restart them unless they can see their way to making a fair profit. At present the profit must be small, where a producer has to buy his materials in the open market, and has to give anything like the present prices for them.

The exports of pig iron from the Cleveland district have this month amounted to 76,982 tons, as compared with 68,858 tons last month, and 84,344 tons in April last year to 22nd. The exports have kept up very well indeed when it is taken into consideration that the navigation season commenced so early this year. Local consumption also is good, and a large quantity of hematite pig iron is being forwarded to the Sheffield district.

Makers generally maintain their quotations fairly well, as they are for the present independent of the market, but second hands have reduced their prices 3d. per ton for all kinds of pig iron; they, however, have only been selling small lots for delivery before the end of the month. Of No. 3 Cleveland pig iron sales have been made at 37s. 9d.; while No. 1 was 39s.; No. 4 foundry, 37s. 3d.; and grey forge, 36s. 9d. Cleveland white iron is practically unprocurable. In the absence of business and the desire to do it, reliable prices for forward delivery can hardly be given. Cleveland warrants have this week touched a lower price than has been known since January 14th, 37s. 8d. cash being all that the buyers would give on Monday. There has since been a slight recovery, and on Wednesday afternoon 37s. 10d. cash would be given, there being sellers at 37s. 11d. The stock of Cleveland pig iron in Connal's stores on Wednesday night was 190,256 tons, an increase for the month of 2782 tons. It might have been expected that with such excellent shipments and inland deliveries iron would rather be drawn out of than put into the public stores.

Finished iron and steel manufacturers have booked very few orders since before Easter, but they are well supplied with contracts, and can keep their establishments in full operation. There is, therefore, no easing of prices. The managing director of one of the leading bar-making establishments in the North of England states that never since their works were founded has business been so brisk as it is at present; indeed, orders have been coming in so rapidly that they were unable to keep pace with them, and there seems to be every prospect of a still more active trade. The question of a restart at the Darlington Steel Works, which have been idle since October, 1894, is much discussed. The directors had a meeting last Saturday, when the subject was considered, and a further meeting is to be held, so as to settle upon the proposal to be made to the shareholders at the forthcoming annual meeting. It is true that the selling prices of steel rails have gone up, but the cost of production has increased likewise, and the directors seem to be doubtful about the present activity being maintained. The inland situation of the works tells against them in their competition with the manufactories near the seaboard. Deliveries of rails and railway material, as well as bridge work, are very heavy from the Tees, and it is a long time since Middlesbrough Dock has been so crowded with large steamers as it is at present, most of them bound for India and Japan. Heavy steel rails are obtainable at £4 12s. 6d. per ton net at works.

The steel ship-plate trade is very brisk, as shipbuilders in the North of England and Scotland are so actively employed. On the Tyne especially is this the case, a considerable proportion of it being work for the British Government. This week orders have been placed with Palmers' Shipbuilding and Iron Company for two thirty-knot torpedo boat destroyers, and other two are to be built by Messrs. Hawthorn, Leslie, and Co. Palmers have now on hand for the British Government eight torpedo boat destroyers, and two third-class cruisers. Owing to the improved prospects, the value of Palmers' shares has considerably increased. A short time ago their £15 A shares could have been bought at 7½, now they are 9½ On the Tyne there are at present ordered eighteen war ships, including torpedo boat destroyers, and of these thirteen are for the British Government. The Tyne Iron Shipbuilding Co. will build a steel steamer of 3400 tons gross for the Stag Steamship Co., and Messrs. Ropner and Sons, Stockton, will build a steel steamer of 5400 tons deadweight, for a Cardiff firm, the price, it is stated, being £30,000. Owing to the activity in shipbuilding the price of steel plates is strongly upheld at £5 2s. 6d. per ton, and some firms will not sell under £5 3s., both less 2½ per cent. and f.o.t.

Wages questions continue to come to the front, the improvement in trade having led the men to endeavour to secure a larger share of the realised prices. At the foundries the men have commenced an agitation for increased wages, and those at the Anderston Foundry, Port Clarence, are the first to hand in a definite claim, which is for no less than 15 per cent. advance. The Northern United Enginemen's Association, which includes cranemen and firemen, have accepted the offer of the employers, an advance of 1s. per week in wages for those receiving 25s. per week and upwards, and 6d. for those under 25s. The pattern makers have agreed to accept an advance of 1s. per week. The joiners of the Tees, Hartlepools and the Tyne yards claimed 3s. per week advance, and the employers offer 1s. from May 6th; the men have this offer under consideration.

The death is announced of Mr. Thomas Walker, of Saltburn, a partner, since its formation in 1872, of the firm of Walker Maynard and Co., Redcar Ironworks.

The employés of the Cleveland Bridge and Engineering Co., Darlington, on Monday presented an illuminated address, a gold pendant, and a silver kettle to Mr. Edward Westby Jacob, who is retiring from the managership of the works, which he has held for the last ten years, during which time the works had been considerably extended.

A testimonial from the working men and others in South-East Durham was on Saturday presented to Alderman Joseph Richardson, D.L. Mr. Richardson is senior partner in the firm of Richardson, Duck and Co., shipbuilders, Thornaby-on-Tees. The University of Durham have conferred the honorary degree of D.C.L. upon Sir David Dale, Bart., who has for so many years been a leading member of the iron and coal trades in this district, and has done so much to popularise the principles of arbitration and conciliation in disputes between employers and their men. He took a prominent part in establishing the Board of Conciliation and Arbitration for the North of England Manufactured Iron Trade, which has successfully adjusted industrial difficulties in that industry since 1869.

The traders of Middlesbrough and district have commenced to agitate for an enlargement of and a new entrance to the Dock, which is the property of the North-Eastern Railway Company, as there is not accommodation for the very large vessels that are now employed in the trade between this country and India and the East, a trade in which Middlesbrough is very largely engaged, as so much railway material and bridgework is manufactured in the district for that part of the world. The trade up till within the last few years has been carried on with steamers of from 2000 to 4000 tons, and the dock and entrance were capacious enough for these. But of late the tendency has been to greatly enlarge the capacity of the vessels employed, as it is found that steamers of from 7000 tons upwards can be worked much more economically, and lower freights can be accepted without loss. But there is not adequate accommodation at Middlesbrough Dock for such vessels, and the consequence has been that they have frequently to take only a part of their cargo on board in the dock and fill up elsewhere. Some vessels are too wide to get into the dock at all, and some of the leading shipowners decline to risk sending their vessels. Not only is the entrance too small, but there is not room enough to swing the vessels if they were in. It has been decided to send a deputation to the directors of the North-Eastern Railway Company, to represent to them the necessity of making adequate provision for dealing with these large vessels. The dock at Middlesbrough was opened in 1842; in 1852 it passed into the hands of the railway company; in 1872 it had to construct a new entrance; and in 1883 it had to make a still larger entrance and to enlarge the dock considerably. If the trade is not to be hampered it will be necessary without delay to still further increase the accommodation. Some traders are of opinion that it would be well if the example of Antwerp could be followed, and quays erected with deep water berths in the lower reaches of the river. That would make the port a less expensive one. The suggestion that a new dock independent of the railway company should be constructed lower down the river does not find favour with the traders.

The steam coal trade is exhibiting improvement, and the collieries north of the Tyne are doing better than for six months past, while the price of best steam coal has been this week raised 3d. per ton, viz., to 8s. f.o.b. Blast furnace coke is scarce; the supply was not in excess of the requirements before the Brancepeth explosion, and now consumers cannot get all they need. Brancepeth Colliery was probably the largest coke making establishment in the country, and the stoppage of the business there could not but seriously affect the supply. This week fancy prices have had to be paid by those needing coke at once, but contracts over three or six months can be placed at 14s. delivered at the Tees-side furnaces.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The pig iron market has been comparatively quiet this week. Scotch warrants are only in moderate request, hematite being slow of sale, while Cleveland iron is much neglected. There is scarcely any speculative interest in Glasgow market at present. Prices are already such that an early rise could hardly be expected; and, on the other hand, the "bears" do not appear assured that the time has yet arrived for a very decided fall. Business has been done in Scotch warrants from 46s. 1½d. to 45s. 11d. cash, and 46s. 3½d. to 46s. 1d. one month. Cumberland hematite has sold from 48s. 1d. to 47s. 9d. cash. Cleveland warrants have changed hands at 37s. 10½d. one month.

There are 43 furnaces producing ordinary, 35 hematite, and 3 basic iron, the total of 81 comparing with 75 at this time last year. Only a small quantity of iron has been added to the stock in Connal and Co.'s Glasgow stores.

Prices of G.M.B. iron are 3d. to 6d. per ton lower, and the special brands are not quite so steady as of late. Govan and Monkland, f.o.b. at Glasgow, Nos. 1, are quoted at 47s. 3d.; Nos. 3, 45s. 9d.; Carnbroe, No. 1, 47s. 6d.; No. 3, 46s.; Gartsherrie, Calder, and Summerlee, Nos. 1, 50s. 6d.; No. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 48s. 3d.; Glengarnock, at Ardrossan, No. 1, 50s. 6d.; No. 3, 46s.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s.

Good shipments of Scotch pig iron are being made to Italy, but in other directions the export trade does not show any improvement. The past week's shipments have amounted to 7937 tons, compared with 8695 in the corresponding week of last year, and of the total there was sent to Italy, 2800 tons; Germany, 810; India, 145; United States, 25; Russia, 170; Australia, 245; France, 30; Holland, 394; Belgium, 35; China and Japan, 160; other countries, 86; the coastwise shipments being 3037, against 6032 in the same week of 1895.

The finished iron industry is fairly active, but competition is keen, and prices are thereby kept down. The steel works are very busy, with good prospects as to the future, orders coming in freely, both for shipbuilding and general engineering work. It is reported that the tender of a Clyde firm recently sent to the United States, for 3000 tons of railway bridge material, has been found to be the lowest—cost, freight, &c.—but it is considered doubtful whether the order will be sent here. Be this as it may, the incident is instructive as to the ability of our steel makers to cope with competition abroad, at least in this particular kind of material.

There are one or two somewhat more hopeful features in connection with the coal trade, which on the whole stands much in need of improvement. A brisk demand is experienced for small coal and dross for manufacturing purposes, and the shipments abroad are this week considerably larger, the quantities despatched from the East Coast to continental ports being heavier than for some time. The prices f.o.b. at Glasgow are: For main coal, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; and steam, 7s. 6d. per ton. The tone of business in Ayrshire is steadier, although there does not appear to be any considerable increase in its volume.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

The coal trade is slightly brisker, and holiday influences are steadily wearing off. The coal shipments from the port of Cardiff for the past week were 305,000 tons. This is very satisfactory, and indications are that it was not a sudden boom but the prelude to a large export during the month. "Big steamers" have been again in evidence, the Pindari for Colombo with 7700 tons, the Samoa for Bombay with 8000 tons, and Oriscalli for the same port with 6000 tons. Swansea coal shipments last week were encouraging, 31,000 tons, though it was reported that the San Francisco trade is quiet. Newport has exported 47,270 tons foreign, and 21,919 tons coastwise.

The anthracite trade between Swansea and Germany is improving, and coal totals for that destination take second rank in importance with those for France. It is hoped that, as the season advances, and business with San Francisco improves, the weekly total of anthracite exports from Swansea will begin to take good distinctive form.

There has been some little trace of discontent noticed amongst the Plymouth colliers with regard to the settlement of the "test case," but I am glad to state that at a meeting of colliers on Monday the matter was satisfactorily explained, and a vote of confidence in Mr. David Morgan, the miners' agent, passed unnamimously.

The impartial notice of the "discharged note" question in The Engineer of last week reminds me that a short time ago I had an interview with an old miners' agent, and a long discussion of the subject took place, and though I knew that a good deal of feeling had been imported into the matter, it was a subject of surprise that so much intense excitement had been aroused. The men were stubbornly bent at all hazards, if refused, to throw down their tools, and the prompt action of the coalowners and of the Sliding Scale Committee, in frankly and even genially abandoning the situation, has done a good deal towards bringing about a better understanding. "Mabon's" action in the affair has been warmly commended, and there is but one opinion, and that a warm one, about the good services of Sir W. T. Lewis, Bart.

Colliers, like those "who go down to the deep in ships," seem to be perversely reckless. Two men from the Dowlais Collieries were fined this week for having tobacco pipes in their possession in Bedlinog colliery last week.

On 'Change mid-week, Cardiff, the mustering of members was gratifying, and business was regarded as healthy in coal, coke, and fuel. Best steam coal was in demand at 10s. 3d. to 10s. 6d.; seconds ranged from 9s. 9d. to 10s.; ordinary seconds, 9s. 3d. to 9s. 6d.; drys, 8s. 9d. to 9s. 3d.; best Monmouthshire, 8s. to 8s. 3d.; seconds, 7s. 9d. to 8s.; very best small, 4s. 9d. to 5s.; best, 4s. 3d. to 4s. 6d.; drys and inferior generally, 3s. 6d. to 3s. 9d. The house coal trade is now unmistakeably upon the down grade. The green winter has been followed by an early spring, and all hopes of a good house coal demand appear to have been abandoned. Quotations remain much about the same, but prices vary a good deal with the conditions. Best, 10s. to 10s. 3d.; No. 3 Rhondda, 9s. 6d.; brush, 7s. 9d. to 8s.; small, 6s. to 6s. 3d.; No. 2 Rhondda, 7s. to 7s. 6d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Pitwood continues weak.

Good trench on Saturday was offered in Cardiff from 14s. 9d. to 15s. Iron ore imports are becoming more noticeable, and prices are quoted in Cardiff firmly as follows:—Rubio, 11s. 9d.; Tafna, 11s. to 11s. 3d.; Garucha, 10s. 9d. to 11s. Large consignments came in this week. Cyfarthfa had several cargoes, Blaenavon three, Dowlais three; Mr. Howard, Ebbw Vale, and Briton Ferry, one each. I was pleased to see an abundant supply in all sorts of places around the Cyfarthfa furnaces this week, and a much better despatch of tin bar from the same quarter. Preparations are going on at Cyfarthfa for resuming the steel rail trade, which has been partially abandoned on account of the demand for steel bar for tin-plate destinations. It was reported on 'Change, Cardiff, this week, that the demand for steel bars is getting less, and that the highest price obtainable for Bessemer quality is £3 17s. 6d., while Siemens is quoted at £3 18s. Heavy steel rails are down from £4 10s. to £4 12s. 6d., light sections are at £4 17s. 6d. to £5 5s. The prices of ship plates are well maintained, and steel scrap, rail and bar ends, &c., are caught up.

A more varied list of quotations, iron and steel, was given this week at the Swansea Exchange, as follows:—Pig iron, Glasgow warrants slightly lower, 46s. cash buyers; Middlesbrough, No. 3, 37s. 9½d.; hematite, 45s. 6d.; Welsh bars, £5 10s. to £5 12s. 6d.; sheet iron, £6 15s. to £6 17s. 6d.; steel, £6 10s. to £6 12s. 6d.; steel rails, heavy, £4 10s. to £4 12s. 6d.; light, £4 17s. 6d. to £5 7s. 6d.; Bessemer steel, bars, £3 17s. 6d.; Siemens best, £3 18s.; tin-plates, Bessemer coke, 9s. to 9s. 1½d.; Siemens, 9s. 1½d. to 9s. 3d.; ternes, 16s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 12s. 9d.; block tin, £59 12s. 6d. to £60 2s. 6d.; lead, £11 to £11 2s. 6d.; Spanish, £10 17s. 6d. to £11; copper, advancing £45 6s. 3d. to £45 8s. 9d.

Other Swansea quotations are:—Anthracite, best, 11s. to 11s. 6d.; seconds, 9s. to 10s.; ordinary, 8s. to 8s. 9d.; steam, 9s. to 10s.; bituminous, No. 3 Rhondda, 9s. 6d. to 10s.; No. 2, 8s. 6d. to 9s. 6d.

Coke continues to advance, implying increased activity in the iron trade. Last prices Cardiff, were, 12s. 9d. to 15s., furnace; foundry, 15s 6d. to 19s. 6d., according to brand.

Patent fuel in fair demand, Cardiff and Swansea.

There is still not much movement to record at the iron and steel works; Cyfarthfa is to have its resident London agent, though of course, from time immemorial, Cyfarthfa has had its representative in the city. All that can be stated about the trade is that prospects are more hopeful. Better news reaches me from the tin-plate districts. Last week there was a larger shipment than make, reducing stocks, and gratifying news is to hand that several works are going to restart. One notable case I am glad to announce is that of the Beaufort Works, Morristown, by concession of the men.

I regret to announce that the tin-plate trade is very depressed at Briton Ferry. The mills at the Vernon, Gwalia, and Villiers are still idle, and there is no prospect of a restart unless the men see the wisdom of following the steps of others, and make a reduction. This is what I have on various occasions pointed out as an imperative necessity, to take a leaf out of iron and steelworkers' books. If these had stubbornly contended for old wages, furnaces would now be as deplorably hard off as mills. The mills at Baglan Bay and Earlswood are fully occupied.

Production of tin bar at Albion and Briton Ferry is a fair average.

I note that Wales is importing freely pig from Ulverstone, and iron bars from Workington.

I referred lately to the possibility of a new industry at Swansea, and the likelihood that the waste sulphate of soda in the district would be utilised for the treatment of sulphide ores from Australia. This is now made tolerably sure by the arrival of the steamer Buluwayo from Port Pirie, South Australia, with a cargo of 3006 tons, and new works are planned to be adopted for the process forthwith.

Opponents of the movement in London for obtaining Welsh water, and who think that it has collapsed, may be interested to learn that a steady survey is still going on in certain localities, tending to indicate that if carried out Langorse Lake will figure conspicuously.

It is stated at Milford Haven that a subsidy has been granted to the Milford Dock Company by the Admiralty for the use of their large graving dock at Milford when required by them. This dock is 600ft. in length, and considered to be one of the finest dry docks in the kingdom.

It has been decided, adverse reports notwithstanding, to proceed with the Llanelly Harbour Bill. The Docks Committee have held several meetings of late, when all matters in reference were well discussed, and they now report that they expect the Bill will come before the House of Lords Committee next week, when all matters *pro* and *con.* will be dealt with in evidence.

I share with many a good deal of interest in the fate of our Welsh Bills, which, as I close my dispatch, are coming to the front. The first is the Great Western Additional Powers Bill for lines in Roath, and improvements in connection with the Bute Docks. Then comes the great struggle, the proposal to amalgamate the Bute Docks and Rhymney. Next, the proposal to form the Windsor Docks on the mud flats between the Taff and Ely rivers. This is expected to be strongly opposed. Then we have the proposal of the Barry Company to get into the Monmouthshire coalfield, and some minor Bills of less significance. These I have mentioned are certain to bring out the best powers of promoters and counsel.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

The trade in iron and steel is improving steadily all round; material changes, either in prices or demand have, however, not taken place, and there is, consequently, not much of interest to be related this week.

Business on the Silesian iron market continues strong. The favourable influence of the Russian commercial treaty is now being felt, especially in the steel and hardware trade, where a steady and altogether satisfactory employment prevails.

Exports in machines to Russia have also been pretty large for some weeks past, the prices realised being, as a rule, fairly remunerative.

Though heavy contracts are not being booked just at present, the activity on the Austro-Hungarian iron market continues, on the whole, satisfactory, owing to the numerous orders that were secured some weeks ago. During the first three months of the present year, the convention of the rolling mills sold about 75,000,000 kilos., which shows a plus of about 23,000,000 kilos. against the same period last year. There is an exceedingly brisk business done in girders and structural iron, and the railway and engineering department is also in fair employment.

On the French iron market raw as well as finished iron finds good markets, and prices are tolerably firm, but have not perceptibly changed since last week, merchant bars being offered at 150f. p.t., girders 160f. p.t., while steel rails were sold at 115f. p.t. free at works.

A lively tone prevails on the Belgian iron market, and prices have been rather more paying of late. Pig iron is in quiet but regular demand, while the various sorts of malleable iron continue to be very actively inquired for. Quotations are, as a rule, tending upwards. Luxemburg foundry pig is quoted 53f. p.t.; common forge, 52f. to 53f. p.t.; merchant bars, No. 2, f.o.b. Antwerp, 122·50f.; No. 3, 127f. p.t.; the same Belgian station, 132·50f. and 137·50f. p.t. Girders, f.o.b. Antwerp, 122·50f. p.t.; the same Belgian station, 130f. p.t. Heavy plates for export, No. 2, 138f. to 140f. p.t.; No. 3, 148f. p.t.; sheets, free Belgian station, 162f.; in some instances, 165ft. p.t.; steel plates, 143f. to 145f. p.t. Steel rails, 113f. to 115f. p.t.

During the first quarter of 1896 201,770 t. pig iron were produced in Belgium, against 222,800 t. for the same period the year before; 75,795 t. being forge pig, against 109,809 t. last year; 21,325 t. foundry pig, against 26,100 t.; and 104,650 t. basic, against 86,900 t. for the corresponding period the year before. On April 1st of present year there were 28 blast furnaces in blow in Belgium, out of 44 built.

On the Rhenish-Westphalian iron market a good number of orders have been coming in upon the week, and prospects for spring demand are most encouraging. Export trade has also perceptibly improved of late. The week's business in pig iron has been on rather a large scale, and quotations are beginning to be more remunerative. The same may be told of the manufactured iron department. In bars and girders quite an animated business is doing; hoops are, likewise, in good request, and as for plates and sheets, the mills have not been so well employed for months. The number of orders that come in at the foundries and machine factories increases from week to week. The situation of the tube foundries, on the other hand, appears to be but slowly improving; prices are fluctuating, and have, in a few instances, even been moving in a downward direction. This may chiefly be accounted for by the exceptionally large stocks, which have been increasing all through last winter, and now concessions have naturally to be made to clear the stocks. The occupation of the wagon factories continues a good one.

Total output of coal in the Saar district was, for the first quarter of 1896, 1,470,070 t. against 1,283,090 t. for the same period last year; output in Silesia amounted to 3,491,470 t., against 3,117,010 t.; in the Ruhr district 9,218,130 t., against 8,344,120 t.; and in the three districts together, 14,179,670 t., against 12,744,320 t. for the same period last year. This shows an increase of 14·6 per cent. for the Saar district, 12·0 per cent. for the Silesian districts, 10·5 per cent. for the Ruhr districts, and 11·2 per cent. for the three districts together, when compared to the production for the same period the year before.

Negotiations are reported to be carried on between the Russian Government and German locomotive factories concerning the supply of about 300 locomotives worth M. 19,000,000. One-third of this order is to be carried out before the end of present year, while the remaining two-thirds will be delivered in 1897.

In 1895 output of gold in Russia is stated to have been considerably lower than in previous years; while in 1893 no less than 2664 pud were washed, output in 1894 decreased on 2483 pud, and last year amounted to 2406 pud only. This decrease may partly be accounted for by the exceedingly dry summer in East Siberia, which, for a time, prevented the gold washing in the rivers, and partly because there was much difficulty in securing labourers, a great number of them being employed in the less fatiguing and much more remunerative work for the Siberian Railway.

The following shows foreign trade of the Low Countries in iron and metals for 1895. In import, the largest figures fall to Great Britain, Germany, and Belgium. There were imported, iron manufactured goods as well as raw iron, worth 90·4 million florins; copper and copper articles, worth 49·1 million florins; steel and steel manufactured goods, worth 49·7 million florins; lead and lead articles, 16 million florins; zinc, for 12·5 million florins; tin, worth 20·2 million florins. With regard to export in iron and iron manufactured goods, which was worth 75·4 million florins, England, Germany, and the Dutch Colonies in East India are the chief consumers. Copper and copper articles (48·4 milllion florins) chiefly go to Germany; steel and steel manufactured goods (17·4 million florins) are exported to different countries. In plates and bars export to Germany is most important. Rails (11·2 million florins) are chiefly sent to the East Coast of Africa and to the Dutch Colonies in East India, while for steel wire (5·6 million florins) Great Britain is the chief consumer.

AMERICAN NOTES.

(*From our own Correspondent.*)

New York, April 16th.

Weakening prices for iron and steel are among the probabilities of the next thirty days, unless something unusual happens. The reason is current requirements are not heavy. Pig iron production is 750,000 tons ahead in stocks. Current weekly production is close on to 200,000 tons. Consumption is 180,000 tons, or perhaps under. A break in the billet pool is a possibility, and besides we have always to reckon with the sudden and unexpected. Buyers have suddenly turned their backs on the market. They never recognised 2·00 dols. coke and 4·00 dols. Bessemer ore as fair, and with the hanging-back demand they now say they will wait and see. Political questions are pressing, and politicians are at sea. The semi-centenary of the Pennsylvania Railroad was celebrated this week. The capital stock is 129,301,600 dols.; lines owned and controlled, 9077; investment, 857,000,000 dols.; gross receipts last year, 132,720,000 dols.; operating expenses, 92,859,286 dols. for 1895; net earnings, 39,861,525 dols.; passengers carried, 75,052,479; tons of freight carried, 160,410,144. The recent rumours of enlarged railway construction are encouraging the iron trade. Much mileage is projected, and in several localities there is urgent need of construction of short lines. The gold craze is now on; large parties are going to Alaska. The inquiries and orders for machinery are increasing steadily. In the smaller industries conditions are improving. Projected enterprises in railway and manufacturing plant and mining developments involve enormous outlays, and if the general conditions warrant such expenditures, iron and steel capacity could be fully engaged.

Testing Armour for Russia.—Last week the first test of armour plate was made by the Carnegie Company for the Russian Government, by the courtesy of the United States officials, at the Indian Head proving grounds. The plates submitted represented a group of 350 tons of armour now ready for shipment to Russia. It was a 5in. double-forged plate, the first thin armour to be subjected to that process. The test was conducted under Russian requirements, which were that the plates should repel the projectiles. Two shots were fired, one of a 4in. and the other of a 5in. shell, with a velocity of 1700ft. a second. Both shells failed to penetrate the plate, and as the test was satisfactory, the group will be accepted. The value of the armour represented in the test was between 125,000 dols. and 150,000 dols.—*American Manufacturer.*

The Incorporated Association of Municipal and County Engineers.—The twenty-first voluntary pass examination of candidates for the offices of municipal engineers and surveyors to District Councils carried out by this Association was held at the Institution of Civil Engineers on Friday and Saturday, the 10th and 11th inst. Twenty-seven candidates entered, and twenty-three presented themselves for examination, the written portion of which was taken on the first day. The greater portion of the second day was occupied with the *vivâ voce* portion of the examination. The examiners were:—I. For Engineering, as applied to Municipal Work, W. Santo Crimp, M. Inst. C.E. II. Building Construction, J. Senior, M. Inst. C.E., past-president, superintending examiner. III. Sanitary Science, J. Lobley, M. Inst. C.E., past-president. IV. Public Health Law Work, J. T. Eayrs, M. Inst. C.E., past-president. The next examination will be held at Liverpool in October next.

LAUNCHES AND TRIAL TRIPS.

On the 14th there was launched from the shipbuilding yard of Messrs. Joseph L. Thompson and Sons, North Sands, Sunderland, a steel screw steamer built to the order of Messrs. Joseph Brown and Son, of Old Castle Buildings, Liverpool. The vessel is of about 4850 tons deadweight capacity, and is constructed in accordance with Lloyd's rules for highest classification. The engines are of the triple-expansion type, by Messrs. John Dickinson and Sons. On leaving the ways the vessel was named Netherfield by Miss Amina Brown, of Liverpool, daughter of Mr. Joseph Brown.

On Saturday, the 18th inst., the s.s. Clarence, which has been built to the order of Mr. F. le Boulanger, of Swansea, by Messrs. Craig, Taylor and Co., of Thornaby-on-Tees, proceeded to sea on her trial trip, which proved highly satisfactory. The engines, which have been constructed by Messrs. Westgarth, English and Co., Middlesbrough, worked without a hitch, and a speed of about 11 knots was maintained during a run of over three hours. The dimensions of the boat are as follows:—254ft. by 37ft. by 18ft., the engines being 19in., 31in., 51in., by 33in. stroke, with two large boilers working at 160 lb. pressure. The owner was represented by Mr. George Eldridge, of London, and Captain F. Dinan, the atter of whom will take command of the vessel.

During the current month Earle's Shipbuilding and Engineering Company, of Hull, have delivered to Messrs. Thos. Wilson, Sons, and Company, of the same town, a fine steel screw steamer named the Dido, 400ft. long, built for the Bombay trade, and capable of carrying 7200 tons deadweight; they have completed and handed over to the representatives of the Haytian Government, after successfully carrying through her speed and gun trials, a 16-knot steel gunboat, named the Crête-à-Pierrot, of 950 tons displacement, constructed under the superintendence of Sir E. J. Reed, K.C.B.; also the steam trawler Argo, owned by the Ocean Steam Fishing Company, of Grimsby; and they have in addition engined the trawler Prince, which has been built at Beverley for the Grimsby Anchor Steam Fishing Company. There is still a good share of Government and private work in hand at this yard.

Messrs. John Scott and Co. launched from their yard on the 16th the screw steamer Giang Seng, which they have built for a Chinese gentleman in Singapore. The dimensions are:—Length, 240ft.; breadth, 34ft.; and depth to main deck, 17ft. 6in. The builders have also supplied and fitted the triple-expansion engines of 160 nominal horsepower, with two large steel boilers having a working pressure of 170 lb. The vessel has been built for the coasting trade round Singapore. She will carry 1500 tons of cargo, and steam eleven to twelve knots per hour. She has a Board of Trade passenger certificate, and can accommodate twenty first-class passengers above awning deck, thirty second-class passengers in the poop, and she has also third-class accommodatfon abaft forecastle. The vessel has two teak decks, and has ample accommodation for the captain, officers, and crew. She has been fitted and finished under the superintendence of Captain Follet, who has had a long and successful experience in the trade for which the vessel is intended. The launching ceremony was performed by Miss Lily Follet, of Liverpool. The vessel, as usual, was launched with steam up, and, on leaving the ways, immediately left for Burntisland, where she will load a cargo of coals for Singapore.

On Friday, the 17th inst., Messrs. Wigham, Richardson, and Co., launched from their Neptune Shipyard, Newcastle-on-Tyne, a fine steel screw steamer, which they have in course of construction for the Chinesische Kustenfahrt Gesellschaft, of Hamburg, being intended for their service in the East. The steamer is 310ft. in length by 38½ft. beam. She will be rigged as a two-masted schooner, and is being built to attain the highest class in the registry of the Bureau Veritas and Germanischer Lloyd. She has a handsome clipper bow with a finely carved figure-head. The vessel has been specially constructed for the Chinese coasting trade, and contains handsome, well ventilated and convenient accommodation for a large number of native and European passengers. The engines and boilers are also being constructed by Messrs. Wigham, Richardson, and Co., the former being of the quadruple-expansion type, self-balanced on the well-known Yarrow, Schlick, and Tweedy system, and are intended to propel the steamer at a high speed. This type of machinery is being extensively applied to the better class of vessels, including the large mail steamers building for the Norddeutscher Lloyd. These vessels are to be larger and faster than the Majestic and Campania. A goodly company witnessed the launch, amongst whom were Mr. Drury, of Darlington, and Mr. Sutton, of Newcastle, and Captain Kohler and Engineer Blesing, representing the owners. As the vessel left the ways she was named the Loongmoon by Mrs. John Tweedy, of Newcastle-on-Tyne.

On Thursday, April 16th, Sir Raylton Dixon and Co. launched from the Cleveland Dockyards, Middlesbrough, the handsomely-modelled mail and passenger steamer Albertville, built to the order of Messrs. The African Steamship Company, London, for the Compagnie Belge Maritime du Congo, for the line between Antwerp and the West Coast of Africa. The dimensions of the vessel are:—Length, 365ft.; beam, 44ft.; depth moulded, 26ft. The cabin accommodation will be of very handsome description, fitted for 110 first-class and 60 second-class passengers, with very spacious state-rooms, specially ventilated and provided with every improvement which experience has suggested as suitable for the intended trade and the comfort of passengers in a hot climate. The first-class dining-room is in a large house on deck, panelled with marble and inlaid woods in the handsomest possible manner. The first-class smoking-room, second-class smoking-room, and cabin entrances, are all most elaborately fitted and decorated. The decks are all of teak, and over the mid-ship part of the vessel a teak shade-deck extends to the sides of the ship so as to give shelter from the sun and to form a promenade above for passengers. The second-class saloon is placed aft, handsomely panelled in teak, with tables, revolving chairs, &c. The ship will be lighted throughout with the electric light, and also provided with refrigerating machinery and a large cooling chamber for the conveyance of fresh meat, provisions, &c. Machinery of 2000 indicated horse-power will be supplied by Messrs. Thos. Richardson and Sons, of Hartlepool, consisting of triple-expansion engines, having cylinders 27in., 43in., and 72in. by 48in. stroke, with two large boilers, working at 180 lb. pressure, and fitted with Howden's forced draught. The vessel was launched in the presence of Mr. Frederick W. Bond, of London, the chairman of the African Steamship Company, and named by Mrs. Bond. The Albertville is a similar vessel to the Leopoldville, built last year for the same line, but of larger dimensions and higher speed.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

9th April, 1896.

7500. Securing Picking Bands to Pickers, J. and R. A. Hopkinson, Manchester.
7501. Pneumatic Tires, S. Bunting, Birmingham.
7502. Actuating Fret Saws, A. W. Nightingale, Glasgow.
7503. Velocipedes, J. Robson, Worcestershire.
7504. Cycle Saddles, E. Denman, Bristol.
7505. Blast Pipes of Locomotive Engines, R. Jenkins, Bristol.
7506. Cutting Tool, W. J. Brown, Stockton-on-Tees.
7507. Adjustable Lever-action Spanner, W. H. Williams, Bedford.
7508. Tailors' Measure and Drafting Tape, L. Jackson, Skipton.
7509. Cutters for Boot Heel Paring Machines, W. and E. Douglas, Kingswood.
7510. Waterproof Malt Sack, L. J. Meakin, Burton-on-Trent.
7511. Prismatic Curtain for Advertising Purposes, F. P. Cox, Liverpool.
7512. Taps, C. C. Linindoll, London.
7513. Tambourine, E. Howard, London.
7514. Pocket Knives, E. Stovold, London.
7515. Automatic Apparatus for Grinding Glass, G. E. Winkelmann, London.
7516. Centrifugal Oven for Oil Stoves, &c., G. E. Winkelmann, London.
7517. Multiple-throw Cams, J. Price, D. E. Radclyffe, A. H. Smith, T. Hann, and W. Bromley, London.
7518. Centrifugal Liquid Separators, R. A. Lister.—(*J. de L. Taché, Canada.*)
7519. Adjustable Tent Poles, T. H. Cothill.—(*P. Lewis, Canada.*)
7520. Folding Knives, &c., T. H. Cothill.—(*P. Lewis, Canada.*)
7521. Axles for Wheels of Vehicles, S. Pettit, London.
7522. Pipes for Smokers, D. Hampton, London.
7523. Picking Arms for Looms, A. Sykes and T. A. Audsley, London.
7524. Mitre Board, A. T. Southern, London.
7525. Water-closets, W. Cooper and T. Cooper, London.
7526. Construction of Walls, &c., J. Sheppard and F. Dashwood, London.
7527. Sealing Letters, G. F. Dewdney, Cardiff.
7528. Combined Cameras and Optical Lanterns, B. Doyle, London.
7529. Device for use in Cleaning Buttons, O. Watkins, London.
7530. Electrical Alarm Apparatus, G. H. Atkinson, London.
7531. Knife-cleaning Device, J. W. Ellis, London.
7532. Apparatus for Aerial Navigation, M. Henderson, London.
7533. Covered Wire for Millinery, &c., P. J. Baker, London.
7534. Bottles for Aerated Liquids, &c., W. Kilsby, London.
7535. Magazine Rifles, J. Fell, jun., London.
7536. Oil Presses, &c., M. Skull, London.
7537. Production of Pigments, P. Cannell-Bunn and W. Barrett, London.
7538. Production of Anthracene Compounds, H. E. Newton.—(*The Farbenfabriken vormals F. Bayer and Co., Germany.*)
7539. Supporting Hauling, &c., Ropes, J. Temperley, London.
7540. Apparatus for Raising, &c., Loads, J. Temperley, London.
7541. Apparatus for Raising, &c., Loads, J. Temperley, London.
7542. Cyclists' Riding Brace, A. Breese, London.
7543. Petroleum Engines, D. Best, London.
7544. Waterproof Garments, L. Frankenstein, Manchester.
7545. Cycle Wheels, W. Rodger and B. Southworth, Manchester.
7546. Railway Automatic Brakes, V. B. Beer, Manchester.
7547. Nut Lock, W. Hudson and C. E. Noren, London.
7548. Vaporisers, J. S. Judge, J. McKee, and G. Edmison, London.
7549. Starting Devices for Motors, E. J. Pennington, London.
7550. Steering Devices, E. J. Pennington and A. G. New, London.
7551. Propellers, E. J. Pennington and A. G. New, London.
7552. Gear Wheels, L. C. Papenfus and L. Loewenthal, London.
7553. Crimping Tongs, G. L. Thompson, London.
7554. Corsets, J. Stone, London.
7555. Duplex Tube, J. T. Thorpe, London.
7556. Electric Railways, H. C. Regan, jun., London.
7557. Commutator Brushes, R. Hirsch, M. R. Hirsch, and J. F. Trottman, London.
7558. Treadle Gearing, J. F. Green, London.
7559. Separating Fixed Gases, W. Hampson, London.
7560. Making Cardboard Boxes, H. C. Norman, London.
7561. Baking Pans, R. S. Mains, London.
7562. Eyelets, E. Kempshall, London.
7563. Coating Confectionery, W. B. Phinney, London.
7564. Nail-strip Cutting Machine, J. A. Horton, London.
7565. Manufacturing Cycle Frames, F. A. Ellis, London.
7566. Motor-driven Velocipedes, L. Rub, London.
7567. Ornamental Strips of Clay, W. C. Lawton, London.
7568. Preventing the Stealing of Bicycles, A. G. V. Petersen, London.
7569. Manufacturing Spinning Tops, C. W. McMinn, London.
7570. Small-arms, J. Hourat and J. Castadère, London.
7571. Knitting Machine Cylinders, L. N. D. Williams, London.
7572. Circular Knitting Machines, L. N. D. Williams, London.

10th April, 1896.

7573. Portable Safety Bicycle Stand, J. Mills, Gloucester.
7574. "Gnu" Trouser Guard, R. J. and W. R. Muckley, Cheshire.
7575. Hardening Steel Pens, &c., A. H. Howard, London.
7576. Fire-grates of Refuse Destroyers, C. Christmas, Birmingham.
7577. Bracket for Window-blind Rollers, J. Cook, St. Helens.
7578. Shoe Machine Awls, A. Austin, Stafford.
7579. Kilns, E. H. Davies, Hereford.
7580. Tip-carts, T. Rowan and H. Rowan, Glasgow.
7581. Rotary Motors, W. G. Potter, London.
7582. Printing from Stencils, &c., J. R. Turnock, Hereford.
7583. Root-harvesting Machines, A. S. Logan, Newcastle-on-Tyne.
7584. Preventing the Fraudulent Re-filling of Bottles, R. H. Thomas, Youghal.
7585. Gauge Glasses, J. F. McIntosh, D. M'Callum, and R. Watson, Dundee.
7586. Improved Dust Screen for Windows, E. Young, Glasgow.
7587. Shuttles of Looms for Weaving, H. Whittaker, Halifax.
7588. Electric Ram Lift, T. Meacock, Birmingham.
7589. Manure Drills, J. Hornsby and J. Innocent, Grantham.
7590. Equally Dividing off Spaces, G. Key, Birmingham.
7591. Cycle Gear Cases, W. H. Higgitt and W. Crowson, Birmingham.
7592. Switches for Tramway Lines, H. Schmalisch, Glasgow.
7593. Coiling Spiral Springs, C. A. V. Hallgren, Glasgow.
7594. Mangling Machines, H. C. Longsdon and F. Wilkinson, Keighley.
7595. Displaying Wines, E. A. Edwards and S. Willoughby, Manchester.
7596. New Colouring Matters, Levinstein, Ltd., and I. Levinstein, Manchester.
7597. New Colouring Matters, Levinstein, Ltd., and I. Levinstein, Manchester.
7598. Muffles, J. H. Robinson, Liverpool.
7599. The "Wharam" Screw, W. Wharam, Cheshire.
7600. Boot Finishing Machines, W. and E. Douglas, and C. J. Ward, Bristol.
7601. Machine for Line Shading, L. Bonnaud, Brussels.
7602. Packing Tobacco for Smokers' Use, S. Smith, Norwich.
7603. Motive-power Engine, F. W. Lanchester, London.
7604. Stirrup-irons, A. Hamilton, London.
7605. Metal-shearing Machines, W. B. Challen and Taylor and Challen, Ltd., London.
7606. Waste or Slop Water-closets, A. Hocking, London.
7607. Fire-lighter, S. Russell, London.
7608. Cycle Gearing, O. B. Whitney, London.
7609. Machine Working by Explosions, A. E. Tavernier, London.
7610. Dyeing Straw Plait, T. Lye and W. T. Lye, London.
7611. Pneumatic Tire Valves, J. May, London.
7612. Explosive Projectiles, E. Davies and H. M. H. Goodfellow, London.
7613. Machinery for Drying Tea Leaf, N. W. H. Sharpe, London.
7614. Cycle Plate for Name, &c., J. V. D. Jéquier, London.
7615. Making Steel Sheets, R. Farley and E. Tonks, London.
7616. Tobacco Pipes, H. Allcock, London.
7617. Turbines, S. C. Davidson, London.
7618. Steering Apparatus for Ships, J. Johannsen, London.
7619. Calling the Guard in Trains, J. Chomé, London.
7620. Stopping-up the Key-holes of Doors, J. Chomé, London.
7621. Connecting Electric Circuits, J. D. F. Andrews, London.
7622. Insulating Materials, &c., J. D. F. Andrews, London.
7623. Stoppers for Bottles and Jars, S. Broadhurst, London.
7624. Utilising the Gases from Combustion, A. Guasco, London.
7625. Collapsible &c., Boxes or Cases, E. H. Archer, London.

7627. Packing of Hydraulic Rams, &c., C. Eastwood, Liverpool.
7628. Shovel for Malt, &c., J. K. C. Chesshire, Birmingham.
7629. Pneumatic Tires, J. R. McKie, Liverpool.
7630. Ventilating Arrangements of Ships, G. Walker, London.
7631. Washing Granular Substances, T. Parkinson, London.
7632. Heating Steam Engine Cylinders, W. I. Last, London.
7633. Ink Bottles, D. H. Jones, London.
7634. Pencils, G. W. Johnson.—(*The Eagle Pencil Company, United States.*)
7635. Gear Cases for Velocipedes, W. A. Landau, London.
7636. Shirts, F. G. Metcalf, London.
7637. Tube Scraper, E. Gravesen, London.
7638. Advertising, L. C. Moore, London.
7639. Buffers for Vessels, J. Ciocki, London.
7640. Car Door Fastener, E. A. Manchester, London.
7641. Puzzles, J. G. Gareis, London.
7642. Pulley Block Sheaves, &c., V. L. Regad, London.

11th April, 1896.

7643. Manufacture of Roofing Tiles, A. Weil, London.
7644. Saucers for Flowers and Plants, H. Kinsey, Swansea.
7645. Sleeve Links, A. J. Austin, Birmingham.
7646. Skating Cycle, J. M. Chambers, London.
7647. Tricycles, A. Wichard and G. A. J. Schott, Bradford.
7648. Apparatus for Use of Umpires, R. Gillett, London.
7649. Electric Cables or Conductors, H. Edmunds, London.
7650. Coverings for Electric Cables, H. Edmunds, London.
7651. Tubes for Steam Boilers, O. Meredith, Birkenhead.
7652. Welding Lap-weld Tubes, S. Y. Goddard, Wolverhampton.
7653. Lubricating Cap Washers, C. Brigg, Bradford.
7654. Automatically Weighing Coal, J. Taylor, Glasgow.
7655. Bottling Liquids, W. H. Courtenay, Birmingham.
7656. Ventilating Boots and Shoes, W. Bacon, Coventry.
7657. Cycles, M. Carswell, jun., Glasgow.
7658. Controlling Windows, &c., G. S. Robb, Glasgow.
7659. Drawing Pins, H. Marles, Brighton.
7660. Velocipedes, A. Shelmerdine, Liverpool.
7661. Looms for Weaving, C. Hahlo, C. E. Liebreich, and J. E. Thompson, Bradford.
7662. Beaters for Whisks, Mixers, &c., J. Morton, Wishaw.
7663. Beaters for Whisks, Mixers, &c., J. Morton, Wishaw.
7664. Connecting Metal Pipes, G. Chisholm, jun., Stirling.
7665. Vacuum Motors, A. Shiels, London.
7666. Valves for Beer Engines, A. Bruce, Glasgow.
7667. Treatment of Diseases of the Rectum, O. Schmidt, Cologne.
7668. Vehicles Propelled by Steam, &c., F. Lister, Keighley.
7669. Kitchen Ranges, G. F. Calderwood, J. Learmonth, and the Planet Foundry Company, Ltd., Manchester.
7670. Trilby Cycle Brake, A. F. Germain, Brighton.
7671. Ruling Lines, J. Joly, Dublin.
7672. Furnishing Needle Cases, R. Wheatley, sen., and R. Wheatley, jun., Birmingham.
7673. The "Haggard" Boatswains' Call, E. Emanuel Portsea.
7674. Bottle, G. M. Davies, Cardiff.
7675. Bottle-rinsing Machine, J. Hube, Berlin.
7676. Working Railway Signals, Hurst, Nelson, and Co., Ld., and G. T. Wheatley, Glasgow.
7677. Rein Holder, H. Green and J. Powell, Birmingham.
7678. Letter Boxes, T. Weir, Dublin.
7679. Silent Door Hook for Ships, W. Logan, Sunderland.
7680. Gate Latch, T. B. Heathorn, London.
7681. Direct-acting Pumps, C. G. Krakau, Kent.
7682. Anti-vibration Bicycle Handle, A. W. Murray, Dublin.
7683. Repairing Pneumatic Tires, F. Forrester and T. R. Hewlett, Manchester.
7684. Valves for Pneumatic Tires, J. Cartwright, Birmingham.
7685. Hydraulic Thrust Bearings, C. A. Sadler, Birmingham.
7686. Apparatus for Bending Wood, J. Polke, London.
7687. Apparatus for Making Barrels, J. Polke, London.
7688. Drying and Seasoning Wooden Articles, J. Polke, London.
7689. Egg-shaped Boxes, F. Ginzler, A. Garner, and W. Garner, London.
7690. Lasts for Boots and Shoes, W. Firman, London.
7691. Pneumatic Tires, E. Hale, Liverpool.
7692. Making Vanilline, O. Preu, London.
7693. Generation, &c., of Acetylene Gas, P. Woog, London.
7694. Electric Traction, F. C. Esmond, London.
7695. Detachable Waterproof Sleeves, C. W. Phillips, London.
7696. Neckties and Bows, E. G. Williams, London.
7697. Cigar and Cigarette Holders, J. H. Miall, London.
7698. Umbrellas and Walking Sticks, A. S. Woollett, London.
7699. Holders for Electric Street Lamps, J. Jakoubek, London.
7700. Globes or Glasses for Incandescent Gas Lamps, S. P. Catterson and Sons, Ld., and W. P. Catterson, London.
7701. Heads for Casks, &c., T. G. and A. Stevens, Greenhithe, Kent.
7702. Advertising on Hats, L. M. Engel and H. A. Marler, London.
7703. Levelling and Surveying Instrument, L. E. M. Viard, London.
7704. Apparatus for Tilting Beer Barrels, &c., H. Searle, J. Swallow, J. B. Swallow, and P. H. Searle, London.
7705. Carriage Wheels, A. Reichwald.—(*A. Rezow, Germany.*)
7706. Edge-setting Machines, M. T. Deune and P. Cave, London.
7707. Upholstering Ships' Cabins, J. Finch and J. H. Rider, London.
7708. Buckles, A. Richter.—(*W. Berg, Germany.*)
7709. Manufacture of New Derivatives of Amido- 1 alphyl- 2 alkyl- 5 Pyrazolones, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
7710. Construction of Submarine Bridges, O. Imray.—(*The Channel Bridge and Railway Company, Ld., France.*)
7711. Manufacture of Fuzes or Match Cords, M. Wagner, London.
7712. Compounds of Albumen and Protein Bodies, A. Classen, London.
7713. Sliding and Swinging Sashes of Windows, S. Naylor, London.
7714. Weaving Selvages, G. Browning, W. A. Joheson, and F. Maydwell, London.
7715. Photographic Washing Vessel, A. A. Bradburne, London.
7716. Connection for Electric Light Cables, R. J. Hatton and W. T. Henley's Telegraph Works Company, Ld., London.
7717. Flaying Knife, R. Graeme, London.
7718. Cloths for Filter Presses, A. J. Boult.—(*H. W. J. van O. Bastiaans, Germany.*)
7719. Revolving Receptacles, F. W. Schafer and A. E. Batson, London.
7720. Ornamentation on Palm Leaves, G. Walker, London.
7721. Testing and Disinfecting Drains, C. T. Kingzett, London.
7722. Envelope, G. A. Tydeman and E. Newton, Waltham Cross.
7723. Formation of Printed Designs upon Fabrics, A. Scheurer, London.
7724. Manufacture of Double Barrels for Firearms, P. L. O. de Gérente and Y. A. M. P. Goubaux, London.

13th April, 1896.

7725. Printing Designs upon Calico, I. Frankenburg, Manchester.
7726. Attaching Containers to Stands, T. J. Sturgeon, London.
7727. Sewing Machines, W. H. Dorman, Stafford.
7728. Packing for Taps, Cocks, &c., W. J. Simmons, Bristol.
7729. Show Cases, J. Gibbs, Bristol.
7730. Pasting Machines, J. J. Cramp, Coventry.
7731. Boots and Shoes, C. E. and W. T. Wright, Leicester.
7732. Driving Gear for Cycles, H. B. Webber, Dorking.
7733. Shoulder Pad for Coats, &c., W. H. Sladdin, Brighouse.
7734. Organ Stop, J. T. Hanson, London.
7735. Metallic Packings, J. Wood, Manchester.
7736. Pickle Fork, G. A. Brookes, Manchester.
7737. Marking Patterns, R. Greenhalgh, Manchester.
7738. Raising Nap on Fabrics, J. D. Tomlinson and J. Porter, Manchester.
7739. Machine Belting, J. Sharples, Birmingham.
7740. Attaching Blinds to Rollers, G. M. Davies, Cardiff.
7741. Railway Game, H. J. Tremellen, Newport, Mon.
7742. Colour Game, H. J. Tremellen, Newport, Mon.
7743. Swivels, W. Dipple, Birmingham.
7744. Match-boxes, W. J. Clapp and F. P. Robjent, Newport, Mon.
7745. Casting Partly Chilled Objects, W. H. Browning and J. G. Heywood, Manchester.
7746. Washer for Cleaning Clothing, E. W. Margetts, Stourbridge.
7747. Pneumatic Tires, W. G. Potter, London.
7748. Rotary Motors, W. G. Potter, London.
7749. Vessels for Warming Plates, T. F. Senior, Sheffield.
7750. Closing Gates, E. G. Herbert, Manchester.
7751. Boots, C. C. Hutchinson, London.
7752. Attachment Bosses of Saddles, J. B. Brooks, Birmingham.
7753. Umbrella Ring, F. Roberts, London.
7754. Swivel, E. Wade and W. Mindham, Barnsley.
7755. Swing-bar Balance, J. T. Bucknill, Thornfield Bitterne.
7756. Steam Traps, W. Donald, Glasgow.
7757. Packing for Piston-rods, J. O. Morgan, Newcastle-on-Tyne.
7758. Oil Stoves, A. H. Griffiths and T. B. Smith, Birmingham.
7759. Timing the Game of Billiards, J. Newman, Durham.
7760. Double Pole Switches, F. W. Heaton and H. Smith, Manchester.
7761. Shut-all Bolt for Doors, J. N. M. M. Brisc Dublin.

7762. Trussing Sections of Railways, G. V. de Luca, London.
7763. Stoppering of Bottles, &c., S. H. Baines, London.
7764. Means for Generating Steam, P. Pinckney, Portsmouth.
7765. Machinery for Trussing Straw, R. Maynard, London.
7766. Colouring Matter, J. Y. Johnson.—(*The Badische Anilin and Soda Fabrik, Germany.*)
7767. Driving Gear of Bicycles, P. M. Carter, London.
7768. Rests for Cycles, The Automatic Cycle Stand Ld., and J. J. Shedlock, London.
7769. Heaters, G. A. Watson, London.
7770. Game Apparatus, R. Booth, London.
7771. Prevention of Thefts from Pillar Boxes, D. Shawe, London.
7772. Spiral Spring Tire, H. L. Todd and W. Wright, London.
7773. Lighting of Lamps, R. Godfrey and J. P. Norrington, London.
7774. Machinery for Cleaning Boots, C. C. Eminson, London.
7775. Sewing Machines, M. T. Denne, London.
7776. Process for Hardening Iron, A. Tauxe, London.
7777. Stools, The Patent Stowaway Stool Co., and T. H. Lewis, London.
7778. Method of Closing Bungholes, C. E. Müller, London.
7779. Adjustable Cornice Pole Joints, E. Corbridge, London.
7780. Football and Cricket Boots, W. Barber, London.
7781. A New Cloth Pleater, &c., W. B. Mulligan, London.
7782. Extension Table, H. Grant, London.
7783. Obtaining Gold, W. P. Thompson.—(*E. Wohlwill, Germany.*)
7784. Looms, H. R. Ross, Manchester.
7785. Protecting Ships' Bottoms, &c., J. Sanders, London.
7786. Cravat Attachment, C. A. Jensen.—(*C. J. Schildhorn, Germany.*)
7787. Brakes for Cycles, A. Frampton, London.
7788. Colouring Matters, O. Imray.—(*G. H. Weiss, Germany.*)
7789. Electric Arc Lamps, J. Brockie, London.
7790. Butter Drying Apparatus, T. Bradford, London.
7791. Stop Motions for Engines, L. St. Peter, London.
7792. Corsets, E. and S. Kohnberger, and A. Neumann, London.
7793. Manufacture of a New Product, C. Stahlschmidt, London.
7794. Shade Holders, H. A. C. Hellyer, London.
7795. Shaft and Blast Furnaces, &c., F. Burgers, London.
7796. Obtaining Salt from Brine, W. Shedlock, London.
7797. Driving Mechanism for Funnels, G. R. Gaunt, Bradford.
7798. Letter File, A. Kojer, London.
7799. Inkpot, S. Coppen, London.
7800. Motive Power Engines, W. Clarke, London.
7801. Zoetropic Pictures, B. J. B. Mills.—(*A. and L. Lumière, France.*)
7802. Sterilising Milk, Cream, &c., A. T. Pfeiff, London.
7803. Root Cutting or Pulping Machines, S. B. Bamford, London.
7804. Dress Fasteners, B. A. Spaull, London.
7805. Corn and Seed Drills, J. Wilson, London.
7806. India-rubber Springs, &c., A. G. Spencer, London.
7807. Cycles, C. Hill, London.
7808. Navigable Battle Forts, J. F. Crease, London.
7809. Photographic Apparatus, G. R. Sanson, London.
7810. Wheels, F. W. Horridge, London.
7811. Gun Fitting, A. W. Swallow, London.

14*th April*, 1896.

7812. Drill Chucks, D. Weir, London.
7813. Cycles, W. G. MacIvy, London.
7814. Perambulator-mailcart Bodies, G. P. Taylor, Birmingham.
7815. Wheels of Cycles, R. Malkin and T. Bowyer, Manchester.
7816. Steel Re-heating Furnaces, W. Trewhitt, Middlesbrough.
7817. Taking Photographs, J. Oulton, W. Shaw, and R. H. Adams, Bradford.
7818. Metallic Sound-resisting Board, F. C. Steinmetz, London.
7819. Apparatus for Superheating Steam, G. Sinclair, Glasgow.
7820. Movable Partitions, &c., C. Strapps, Manchester.
7821. Lace-securing Attachment, J. G. Rollason, Birmingham.
7822. Oil Engines, H. N. Bickerton, Manchester.
7823. Trivets, T. le Poidevin, Guernsey.
7824. Cycle Tires, T. Guthrie, Newcastle-on-Tyne.
7825. Apparatus for Compressing Air, M. E. Clark, Manchester.
7826. Polishing Cloth, J. J. Ashworth, Manchester.
7827. Split Pin, J. Barker, Oldham.
7828. Mats for the Seats of Tramcars, H. Haley, Manchester.
7829. Match-boxes, F. Hutchins, London.
7830. Machine for Sowing Turnip Seeds, W. Doyle, Dublin.
7831. Speed of Vessels, J. Davis, Bradford-on-Avon.
7832. Automatic Tapping Attachments, F. A. Errington, London.
7833. Riveting Machines, J. Johnson.—(*C. B. Albree, United States.*)
7834. Electric Railways, A. S. Krotz, W. P. Allen, and O. S. Kelly, Manchester.
7835. Twin Peg and Ball Toy, H. J. Tremellin, Newport, Mon.
7836. Valve Motion of Beer, &c., Engines, A. Bruce, Glasgow.
7837. Linotype Printing Machines, R. H. H. Baird and I. Hall, Glasgow.
7838. Steam Boiler Furnaces, T. Hineson, Ashton-under-Lyne.
7839. Label and Ticket Holders, S. Learoyd, Huddersfield.
7840. Garden Rollers, F. Brangwin and H. F. Baly, London.
7841. Positive Drive for Spindles, T. Sowerbutts and J. Watson, Accrington.
7842. Tilt for Supporting Tarpaulins J. Tilley, North Shields.
7843. Oil Tank Wagons, A. S. Nelson, Glasgow.
7844. Flanging the Manholes in Boilers, W. Fairweather.—(*The Babcock and Wilcox Company, United States.*)
7845. Securing Spokes in Cycle Wheels, A. C. Tennant, Seacombe, Cheshire.
7846. Photographic Cameras, R. Dobson, Glasgow.
7847. Rubber Tires, J. D. Beebe, London.
7848. Car Movers, P. H. Jacobus, London.
7849. Disengaging Boats on Ships, R. Anderson and W. Prentice, London.
7850. Ships' Davits, R. Anderson and W. Prentice, London.
7851. Bottle Labelling Machine, H. S. Grace and A. D. Reynolds, Birmingham.
7852. Music Leaf Turner, H. B. Kirk, London.
7853. Devices for Elevators, Otis Elevator Company, Limited.—(*Otis Bros. and Co., United States.*)
7854. Regulating Electric Motors, Otis Elevator Company, Limited.—(*Otis Bros. and Co., United States.*)
7855. Railway Permanent Ways, J. Butterworth, London.
7856. Typewriting Machines, J. Y. Johnson.—(*The Philadelphia Typewriter Company, United States.*)
7857. Machine for Stoning Raisins, E. Sutherland, London.
7858. Vehicles Propelled by Oil, A. G. New, London.
7859. Retaining Railway Window Sashes, W. Shears, London.
7860. Printed Sheet Delivering Mechanism, W. Scott, London.
7861. Ladies' Improved Skirt for Cycling, W. Evans, London.
7862. Lead Presses, A. J. Boult.—(*H. B. Cobb, United States.*)
7863. Axle-boxes. F. A. Sürth, London.
7864. Hooks and Eyes, J. F. Schoeppl and W. Heeren, Leeds.
7865. Separating Laminated Packs, F. McCarty, London.
7866. Coping Bricks, &c., J. Hamblet and I. Parkes, London.
7867. Band Saw Guides, W. McBeth, Canada.
7868. Drying White Lead, T C. Sanderson, London.
7869. Generating Acetylene Gas, H. A. Kent, London.
7870. Pneumatic Tires, The Scottish Manufacturing Company, Ltd., and A. Macdonald, Glasgow.
7871. Pneumatic Tires, The Scottish Manufacturing Company, Ltd., and A. Macdonald, Glasgow.
7872. Hoisting Mechanism, P. Jensen.—(*P. Egan, United States.*)
7873. Power Transmitters, P. Jensen.—(*P. Egan, United States.*)
7874. Welt-seam Trimming Machines, Z. T. French and W. C. Meyer, London.
7875. Fire Buckets, W. R. Myers, London.
7876. Fire-escapes and Ladders, J. C. Merryweather, London.
7877. Making Carpets, A. H. Brinton and F. E. Tucker, London.
7878. Furnaces, W. R. Jones, London.
7879. Improved Blind Roller, J. W. Griffiths, London.
7880. Coffee Substitutes, R. Haddan.—(*Katreiners Malzkaffee Fabriken mit beschrankter Haftung, Germany.*)
7881. Electric Transformers, J. Devonshire.—(*W. S. Moody, United States.*)
7882. Electric Motors, J. Devonshire.—(*W. B. Potter, United States.*)
7883. Electric Motors, J. Devonshire.—(*C. P. Steinmetz and E. J. Berg, United States.*)
7884. Electric Power Systems, J. Devonshire.—(*E. J. Berg, United States.*)
7885. Incandescent Lamp Bases, J. Devonshire.—(*J. H. and A. Pe lerquist, United States.*)
7886. Tanning Hides, V. Gallien, London.
7887. Fire-grates and Stoves, W. H. Harvey, London.
7888. Producing Aerial Displacement of One or More Performers on the Stage of a Theatre, W. P. Thompson.—(*C. E. Pritchard and J. B. Brant, France.*)
7889. Actuating the Cut-off Gear of Corliss and other Engines, J. S., T. A., and E. R. Walker, Liverpool.
7890. Lamp or Stove Wicks, E. E. Joyce, Liverpool.
7891. Fastenings for Bags and Music Cases, A. D. Southgate, W. G. Southgate, and A. Scherzinger, London.
7892. Plastering Compounds, J. E. Summers and J. H. Ogburn, London.
7893. Radiant Heat Baths, J. H. Kellogg, London.
7894. Making an Alimentary Product, J. H. Kellogg, London.
7895. Ornamental Fabrics, A. H. Kursheedt, London.
7896. Electric Hair Cutters, F. M. Bell and J. L. Sloss, London.
7897. Military Intrenching Tools, &c., T. Rowe, London.
7898. Cultivating Bacteria, H. H. Lake.—(*L. von Lorentz, Germany.*)
7899. Ovens for Drying and Burning Tiles, R. Stanley, London.
7900. Band Brakes, C. R. Hutchings, London.
7901. Apparatus for Mixing Air and Gas, J. M. Mitchell, London.
7902. Carving Machines, S. Pitt.—(*F. Snow, United States.*)
7903. Cages for Fowls and other Animals, C. Hüsgen, London.

15*th April*, 1896.

7904. Coffee, H. Boisselier, Enfield.
7905. Fastening the Soles to Boots, H. W. Boswell, Dartford.
7906. Hemstitch Machines, J. Walker, Belfast.
7907. Breech-loading Guns, E. C. Green, Cheltenham.
7908. Tiles, F. J. D. Hüllinghorst and G. Ewart, London.
7909. Machine for Contracting Tires, W. G. Mullett, Bristol.
7910. Process to Obtain Ammonia, J. Plummer, Midlothian.
7911. Toy Guns, &c., R. Smith, Rishton, near Blackburn.
7912. Toasting Appliances, J. R. G. d'Almeida, London.
7913. Furnaces, E. Johnson and J. Thompson, Lemington-on-Tyne.
7914. Printing Presses, F. Waite and Waite and Saville, Ld., Bradford.
7915. Roller Blinds, J. Oulton, W. Shaw, and R. H. Adams, Bradford.
7916. Boots, R. G. Jones, Swansea.
7917. Combined Boiler, Bath, &c., W. Mould, Birmingham.
7918. Steam-boiler and other Furnaces, J. Murray, Glasgow.
7919. Transit Basket, A. E. Catchpole and Harrod's Store's, Ld., London.
7920. Draught Excluders for Doors, W. H. Kewer, London.
7921. Harrows, R. A. Dennett, London.
7922. Pulley Blocks, G. T. Winnard and J. Bedford, Sheffield.
7923. Supplying Acetylene Gas to Vehicles, T. Durnan, Sheffield.
7924 Axis Tractor, R. C. Macdonald, Glasgow.
7925. Preserving Stud Holes in Shirt Fronts, A. H. Binnie, Glasgow.
7926. Siphon Flushing Cisterns, H. E. Brice, Birmingham.
7927. Waist Belts, H. T. Ollard, Birmingham.
7928. Electric Signal Indicator, M. Mercier, Manchester.
7929. Outer Covers of Pneumatic Tires, A. Latimer, Birmingham.
7930. Rack for Holding Coats, &c., J. Penrose, London.
7931. Inhalatory Appliances, A. M. Hugill and J. Overton, Manchester.
7932. Cabinet-making, J. Schuler and M. Wuzel, Halifax.
7933. Gas Cooking Appliances, E. P. Greenwood, Manchester.
7934. Window Fastener, T. Howard and J. Hallan, Hendon.
7935. Spinning and Twisting Machines, J. Boyd, Lanarkshire.
7936. Firelighter, C. H. Silson and F. Robinson, Bradford.
7937. Harness for Horses, E. Garnier and S. J. Prescott, London.
7938. Loose Socketed Sewer Pipe Joint, C. Lee, London.
7939. Transmission of Power, F. R. Simms.—(*W. Maybach, Germany.*)
7940. Heating Apparatus, F. R. Simms.—(*W. Maybach, Germany.*)
7941. Hardening Steel Plates, J. A. Mays, London.
7942. Smoking Pipe, S. Comoy, Accrington.
7943. India-rubber Stamps, J. S. Elder, Glasgow.
7944. Bicycles, P. M. Staunton, Dublin.
7945. Upright Lever with Centre Spring, J. R. Knight, Blackrock.
7946. Sash Window Fastener, H. Stringer, Willenhall, Staffs.
7947. Sash-lift Bows, B. Drysdale and T. R. Voce, Birmingham.
7948. Combined Trousers and Knickerbockers, B. P. Hughes, London.
7949. Let-off Motions for Looms, J. Crabtree, J. Robinson, and J. W. Haworth, London.
7950. Selvedge Weaving Apparatus, E. T. Whitelow, Manchester.
7951. Compounds for the Inside of Barrels, G. Stacey, London.
7952. Horseshoes, W. H. Crawcour, London.
7953. Manufacture of Stockings and Socks, W. L. Hill, London.
7954. Detachable Buttons, A. E. Webb, London.
7955. Incandescent Gas Burner, &c., C. Howard, London.
7956. Construction of Unions, &c., G. S. Trafford, London.
7957. Boxes, H. and H. Inman, London.
7958. Roofing Tiles, G. Power, London.
7959. Vent Plug, S. H. Robinson, London.
7960. Device for Preserving the Eyesight, B. A. Dorst, London.
7961. Driving Gear for Bicycles, W. D. Scott-Moncrieff, London.
7962. Centrifugal Governors, J. N. and W. Paxman and J. C. Peache, London.
7963. Printing Machines, E. Graber and L. Hepworth, London.
7964. Lamp Chimney, G. Rowlands, London.
7965. Funnel, L. Kemp and J. E. Smurthwaite, London.
7966. Tires for Cycles, F. W. Randall, London.
7967. Lamps, W. Staveley, London.
7968. Bottle and Stopper, W. Youlten, London.

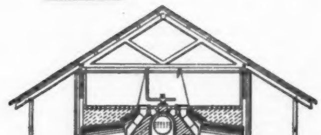
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

553,574. Incinerator, *C. Thackeray, Montreal, Canada.—Filed July 30th*, 1894.

Claim.—(1) An incinerator having a main flue for the products of combustion, auxiliary flues running parallel thereto, suitably controlled communicating passages between the main and auxiliary flues, series of furnaces and combustion chambers laterally adjoining the auxiliary flues, main transverse communicating passages, suitably controlled, between said combustion chambers and the main flue, and auxiliary transverse communicating passages, suitably controlled, between said combustion chambers and said auxiliary flues, for the purpose set forth. (2) An incinerator having a main flue for the products of combustion, a series of main furnaces and combustion chambers laterally adjoining said flue, suitably controlled transverse communicating passages between the combustion chambers and said flue, and a series of auxiliary cells arranged in alternate order with said main furnaces and communicating on each side with same, for the purpose set forth. (3) An incinerator having a main horizontal flue for the products of combustion, a chimney located at one end of same, a central auxiliary flue and outer auxiliary flues running parallel with the main flue, suitably controlled communicating passages between said central auxiliary flue and main flue, series of furnaces and combustion chambers laterally adjoining the outer auxiliary flues, main transverse communicating passages, suitably controlled, between said combustion chambers and the main flue, auxiliary transverse communicating passages, suitably controlled, between said combustion chambers and said auxiliary flues, series of auxiliary furnaces or cells arranged in alternate order with said main furnaces and communicating on each side with same, a steam boiler located in said main flue, and suitable conductors connected with said boiler, and serving to convey superheated steam to said furnaces or cells, for the purposes set forth.

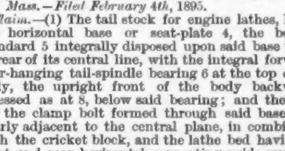
553,574.



553,594. Engine Lathe, *V. F. Prentice, Worcester, Mass.—Filed February 4th*, 1895.

Claim.—(1) The tail stock for engine lathes, having the horizontal base or seat-plate 4, the body or standard 5 integrally disposed upon said base wholly in rear of its central line, with the integral forwardly over-hanging tail-spindle bearing 6 at the top of said body, the upright front of the body backwardly recessed as at 8, below said bearing; and the hole 9 for the clamp bolt formed through said base at or nearly adjacent to the central plane, in combination with the cricket block, and the lathe bed having the front and rear horizontal supporting guide ways, the centrally disposed clamp bolt with its adjusting nut above the foot and beneath the spindle bearing, all substantially as shown and described. (2) The combination of the low cricket block having the top seating surface with transverse guide, the tail-spindle support composed of the base or seating plate adjustably mounted on said cricket block, the body standard integral with said base and standing thereon substantially in rear of the central vertical plane, the back of said body forwardly arched and carrying the integral forwardly overhanging bearing at the top thereof, the tail-spindle mounted in said bearing, the clamp bolt arranged through an opening in said base approximately adjacent to the centre plane, with its operating nut disposed above the top of the base and beneath the bearings, the binding shoe on said bolt, and the set over adjusting screw in said cricket, all substantially shown and described.

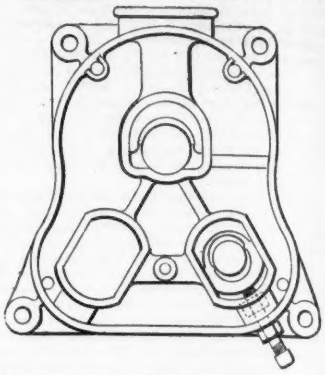
553,594.



553,607. Cane Mill, *C. A. Calvert, Buffalo, N.Y.—Filed July 2nd*, 1895.

Claim.—(1) In a cane mill, an imperforate bottom plate provided with a raised flange or rim forming a pan, and with journal pockets having their walls extended above the bottom of the pan and their bottoms on a level therewith, and provided in their inner walls with openings or passages arranged above the bottom of the pan, whereby the pockets communicate with the surrounding space of the pan, substantially as set forth. (2) In a cane mill, the combination with the bottom plate having a raised rim or flange forming a pan, and a pair of opposing journal pockets extending above the bottom plate, of a horizontal bridge piece connecting said pockets, having a bearing for the lower journal of a scraper and raised above the bottom plate, whereby a space is left between the bridge piece and the bottom plate for the removal of chips, substantially as set forth.

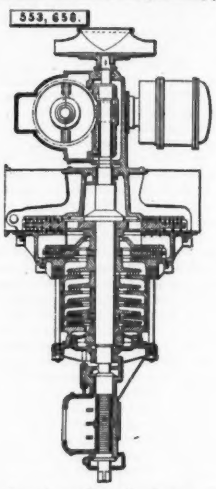
553,607.



553,658. Turbine Motor, *C. A. Parsons, Newcastle-upon-Tyne, England.—Filed February 21st*, 1895.

Claim.—In a steam turbine, a shaft, high-pressure discs thereon having lateral blades, fixed rings intermediate of the discs having lateral blades alternating with the blades of the discs, said rings extending inwardly toward the shaft, and providing passages to direct the steam inwardly and a low-pressure disc of larger diameter having blades on its opposite sides and rings with blades for said disc, said low-pressure disc having perforations at the central portion for the passage of the steam through to the opposite side of the disc, substantially as described.

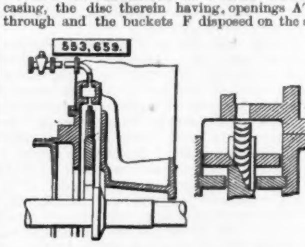
553,658.



553,659. Steam Turbine, *C. A. Parsons, Newcastle-upon-Tyne, England.—Filed February 21st*, 1895.

Claim.—In combination in a steam turbine, the casing, the disc therein having openings A′ therethrough and the buckets F disposed on the sides of the disc, the blades E fixed to the casing and the peripheral buckets B with means for directing the jet thereto, substantially as described.

553,659.



553,700. Marine Boiler, *R. R. and H. L. Zell, Baltimore, Md.—Filed February 24th*, 1893.

Claim.—(1) A steam boiler, comprising side walls made up of series of water-tubes having top and bottom headers, front and rear walls made up of standing headers with intermediate doors, the doors of the one wall being opposite the headers of the other wall, a mud-drum communicating with the bottoms of the headers of the rear wall, water separators communicating with the standing headers at their upper ends and with the top headers of the side wall tubes, cross headers connecting the water separators, curved tubes connecting the cross headers and standing headers, and a steam drum communicating with the water separators and located in the path of the outgoing products of combustion, substantially as described. (2) A steam boiler, having vertical headers forming part of the end walls of the combustion chamber, and water-tubes traversing said combustion chamber diagonally from opposite headers, and doors in the end walls of the combustion chamber between the headers, substantially as described.

NAVAL ARCHITECTURE.—A FEW PRINCIPLES POPULARLY EXPLAINED.

No. VI.—TONNAGE AND FREEBOARD.

THE tonnage of a vessel is a measure of her internal capacity for the stowage of cargo, and must not be taken to represent the weight in tons of the cargo she is able to carry. It affords a rough basis of comparison between the cargo-carrying capabilities of vessels of the same type, but no more than that. The object of its determination is to fulfil an international agreement whereby vessels may be, as nearly as possible, equitably taxed for harbour, light, and other dues. Hence the mode of measuring it is fixed by Act of Parliament, and the measurement itself is performed by officials of the Board of Trade.

The origin of the term "tonnage" is said to have been the number of "tuns" of wine which the hold of a vessel would stow, and hence the word was at first written "tunnage." Be that as it may, the term "tonnage" has been used since the first Act of Parliament was passed in this country, just two centuries ago, to fix a method of determining its value, and insisting upon the tonnage so obtained being inserted upon the vessel's certificate of registry. This document, known as the ship's "register," contains three statements relating to her tonnage, in addition to what is known as her "registered dimensions."

It should, however, be premised that the legalised rules for the determination of a ship's tonnage have undergone many changes, and assumed many forms during these two hundred years. The method now adopted by international agreement was first embodied in the Merchant Shipping Act of 1854, and became law in that year.

We now find upon a ship's register, as already remarked, three expressions relating to her tonnage. These are:—(1) The under-deck tonnage; (2) the gross tonnage; (3) the net register tonnage. The under-deck tonnage represents the capacity for cargo below the upper deck, in all vessels with less than three decks; and below the second deck in all other vessels. The gross tonnage represents the total capacity for cargo to the upper deck in all vessels, and likewise in all covered-in houses and spaces above the upper deck. The net register tonnage is obtained by subtracting from the gross tonnage all legally-allowed deductions, as for crew space, propelling spaces, &c. Hence it is upon the net register tonnage that all dues are paid, and consequently the law requires that the figures representing it shall be deeply cut on the inside of the main hatchway, so as to be readily seen by all officials who seek to do so without having to disturb the cargo.

We have said that the tonnage is a measure of the vessel's capacity for the stowage of cargo. In point of fact, it represents an approximation to the number of cubic feet in the vessel which are appropriated to cargo stowing purposes. In some types of vessels the approximation is a close one, while in others it is not so. In most sailing ships, for instance, the register tonnage is as nearly as possible what its name would indicate, having regard to the ton-unit employed; while in some classes of steamers the deductions for propelling space are so great as to leave a net register bearing but a small proportion to the space actually available for stowing cargo.

Until the year 1854, the calculations for the tonnage of a vessel, as enacted by successive Acts of Parliament, took no account of her form. and consequently two vessels of the same principal dimensions, but with different coefficients of fineness, would have the same tonnage, and therefore pay the same dues. Indeed, between the years 1773 and 1835 the Rule enacted by Parliament for the measurement of merchant vessels did not even take any account of their depth, but simply of their length and breadth. The Rule for Tonnage by Builder's Old Measurement—or Tonnage B.O.M. as it was described—deducted three-fifths of the breadth from the length, and multiplied the difference by one-half the square of the breadth. The product was supposed to be the cubic capacity in the vessel suited for receiving cargo. Then, allowing 94 cubic feet for the stowage of a ton of merchandise, the product just obtained was divided by that number in order to find the tonnage.

If L be the length for tonnage, and B the breadth, then

$$\text{tonnage B O M} = \frac{(L - \frac{3}{5}B) \times B \times \frac{B}{2}}{94}$$

The operation of this rule resulted in vessels being made unduly deep, because depth was not paid for in dues, and hence it led to their instability and frequent loss.

The Act of 1854 represents an intelligent attempt to determine the actual cargo capacity of a vessel by applying the same method for measuring the internal capacity of her hold, as in our first paper was used to determine her immersed volume or "displacement;" so that allowing 100 cubic feet for the stowage of a ton of merchandise, we have the tonnage found on dividing the internal capacity by 100.

The mode of calculating the internal capacity in each case is laid down with great minuteness by the Act of Parliament, but it must be sufficient for our purpose to indicate what is done in general terms.

Let us suppose a vessel 200ft. long. In such a case the law requires the length to be divided into ten equal parts, and the area of the transverse section calculated at each of these divisions of her length. A curve of sectional areas is then formed with the values so obtained, and the area enclosed by this curve and its base is the total cubic capacity of the hold.

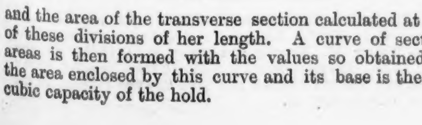

FIG 24

Consider this case in further detail.

Fig. 24 shows the longitudinal elevation of the supposed vessel 200ft. long. T T is the tonnage deck and S S are its extremities, so that the distance S S = 200ft. is the registered length. Now, as we have said, in this case the length is to be divided into ten equal divisions, giving nine sections of the vessel and two end positions of practically no area.

Let Fig. 25 represent a section of the vessel at one of these divisions. Suppose in this case the depth of hold is 16ft., we have then to divide that depth into four equal divisions of 4ft., the upper one commencing at one-third the round of beam below the deck. This gives us five ordinates, as shown on the figure. The lengths of these are carefully measured in the vessel to the inside of the ceiling, and the same is done at each of the other sections at which the vessel is divided. In the case of the ordinates of each section, the even numbered ones—*i.e.*, the second and fourth—are each multiplied by four, the end ordinates by unity, and the odd numbered ones by two. The sum of the products multiplied by one-third the common interval between the ordinates gives the area of the section. The areas at the other sections are found in a similar manner, and a curve of sectional areas constructed therefrom, as shown by Fig. 26. To obtain this curve we draw a base line representing the length of the vessel, which is in this case 200ft., and divide it into ten equal parts at the ordinates numbered on the figure. The area of the section corresponding to each ordinate is set off upon it to the same scale, and the curve drawn through the points so obtained is the curve of transverse sectional areas. The area of this curve gives us the internal cubic capacity of the vessel for cargo, and it is obtained by multiplying the end ordinates by unity, the even numbered ordinates by four, and the odd numbered ones by two. The sum of the products being multiplied by one-third the common interval between the sections, and divided by 100, gives the number of tons, of 100 cubic feet each, which the vessel can stow below her tonnage deck. This is the under deck tonnage as determined by the present tonnage law.

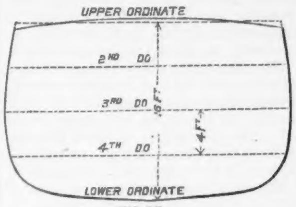

FIG 25

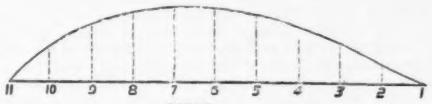

FIG 26

To obtain the gross tonnage we have to measure the cubic capacity of the bridge house, poop, and forecastle, and any other permanent closed-in spaces on the upper deck available for cargo or stores, or for the berthing or accommodation of passengers and crew, and having divided the same by 100, the result is added to the under deck tonnage, and produces the gross tonnage. To obtain the net register tonnage various deductions have to be made for propelling and crew spaces, and for some minor allowances permitted by an Act of Parliament passed in 1889. The rules for calculating propelling space deductions are of an arbitrary character, and their details are too lengthy and complicated to be quoted here.

Such, briefly, are the methods whereby the tonnage of a vessel are obtained. It will be evident that it affords very little information in regard to her cargo carrying capabilities, the latter being always greatly in excess of the register tonnage upon which dues are paid.

Passing from the legalised methods of measuring a ship for registry purposes, we now come to the commercial method as between the builder and purchaser. It is usual now-a-days for the shipowner when inviting tenders for a new vessel to stipulate that she shall have a certain "deadweight" carrying capability on a fixed freeboard or mean draught of water. In some trades it is further insisted that there shall be a certain number of cubic feet of space in the portions of the holds and 'tween decks available for cargo. The latter is the actual internal capacity as contrasted with the fictitious one which the arbitrary deductions of the tonnage laws result in. The former is a true criterion of the vessel's freight-earning capabilities. Deadweight cargoes are those of which the specific gravity is higher than that of water, but the term is usually applied to cargoes much more dense than water, such as pig iron, iron ore, &c. Whenever the cargo carried is of so high a specific gravity that the vessel is loaded down to her full immersion before the hold is full, then that cargo may be considered as deadweight.

Cargoes of such a low specific gravity that when the hold is full the vessel is not immersed to her proper load line, are termed "measurement cargoes;" because the rate of freight in such cases is based upon the cubic capacity occupied, rather than upon the actual weight carried.

The deadweight-carrying capability of a ship is the displacement between the light and load lines.

The measurement capacity is the actual cubic space in hold and 'tween decks available for cargo.

The tonnage laws allow 100 cubic feet of space to a ton; but as 35 cubic feet of sea water weigh a ton, it is evident that the density of a deadweight cargo is at least three times that assumed in the Act of Parliament.

Closely associated with the question of tonnage is that of freeboard, the details of which have been fixed by Parliament for British ships during the past seven years.

The freeboard of a vessel is the height of her upper deck above the load water-line amidships, and its amount is determined in every case by the application of certain clearly defined rules and regulations. The purpose of these regulations is:—(1) To ensure that when loaded a vessel shall have a certain volume of reserve buoyancy in relation to her volume of displacement. That is to say, that the volume of the vessel above the water-line shall have at least a certain ratio to the volume below the water-line. (2) To ensure that the weight of cargo shall not be such as to bring undue stresses upon the parts of the hull. (3) That provided the cargo is properly stowed there shall be enough free side left for purposes of stability. (4) To ensure as far as possible the safety of the sailors in navigating the vessel, against the risk of huge seas washing them from off the deck.

When the freeboard of a vessel is determined, her deadweight capability may easily be found; for, as already explained, it is the displacement between the light line and the water-line passing through the centre of the freeboard disc. The marks put upon the sides of vessels to represent the depths to which they may be legally loaded are very often a subject of mystery to the observer. Fig. 27 shows the freeboard marks on a sailing vessel, and Fig. 28 those on a steamer. We have first, in each case, a line to represent the deck of the vessel, or rather a bar, drawn at what is termed "the statutory deck line." The freeboard *a* is set off below the top of this bar, and it determines the centre of the circle or "freeboard disc." These particulars are common to the two figures, as also are the letters "L. R.," which stand for Lloyd's Register, and denote the society which has assigned the freeboard in the particular case under authority received from the Board of Trade. "B. T." on a freeboard disc means that it was assigned by the Board of Trade; "B. V." means the Bureau Veritas, a continental registry; while "B. C." means the British Corporation of Glasgow. The letters usually seen are, however, "L. R.," as in our illustration.

Turning to Fig. 27, we further see that alongside the disc are two bars, the lower of which, marked W N A, indicates the depth of loading allowed for a winter voyage in the North Atlantic; while the upper one, marked F W, shows the depth to which the vessel may be loaded in fresh water in order that when she gets down a river into the sea she will float with the centre of disc just awash. As we need scarcely remark, a vessel's draught of water always diminishes as she proceeds from fresh water into salt, and *vice versâ*.

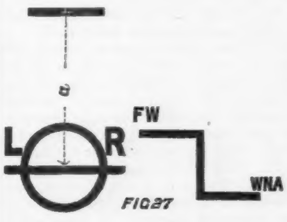

FIG27

As shown by Fig. 28, the marks alongside the freeboard disc of a sea-going steamer are more numerous than on a sailing vessel. Indeed, those shown on Fig. 28 are often spoken of as her gridiron. We find the W N A and F W bars as in a sailing vessel, but in addition thereto there are (1) I S, which means the depth to which the vessel may be loaded for a summer voyage in Indian seas; (2) S, which is the summer or ordinary load-line, and corresponds with the centre of the disc; (3) W. or winter line, for other regions than the North Atlantic.

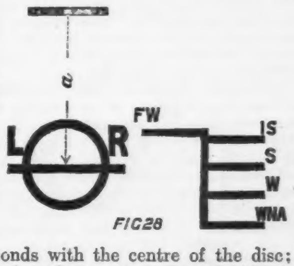

FIG28

Regarding the statutory deck line, it should be explained that the top of the bar is really above the level of the upper deck at the side to the extent of from about 1in. to 2in. In point of fact, the actual distance above the deck is about one-sixth the round in the deck beam. The reason for putting the deck bar above instead of at the deck is not easy to explain. In fact, there is no scientific reason for it whatever. In days gone by, when wooden ships had thick wooden waterways, it was claimed that the freeboard should be measured to the top of the waterway. And now that iron ships have no wooden waterways, but, on the contrary, gutter watercourses instead, the old statutory allowance is still permitted in setting off the deck bar. But since the distance of the bar above the deck is always added to the freeboard determined by calculation, it simply amounts to first adding an inch or two and then taking it off again. There are many such anomalies in all the Acts of Parliament relating to tonnage and freeboard.

HARBOURS AND WATERWAYS.

The Thames.—The report of the Commissioners appointed to inquire into the condition of the lower reaches of the river has been published. This report justifies the appointment of the Commission, if for no other reason than that it has brought to light the fact, that while the shipowners using the river were constantly complaining of the inadequacy of the depth of water to the present requirements of navigation, the channel buoyed out by the Trinity House was not the deepest or most direct, and that there existed, unknown to the officers of the Conservancy Commissioners and every other authority, a channel through the Leigh Middle shoal of 25ft. at low water, giving a foot more depth than is shown on the Admiralty chart or indicated by the Trinity House buoys. It hardly appears credible that on a river like the Thames, having the largest amount of navigation in the world, that there does not exist a regular system of surveying, and that there is not, as in the case of the Mersey, a department charged with this special duty. The last survey was made about sixteen years ago, and this is the only survey on which the pilots had to rely.

The Commissioners now recommend that a marine surveyor should at once be appointed, and be constantly employed to sound and chart the Thames from the Nore upwards. The powers of the Commissioners were unfortunately confined to a small portion of the river, and were too limited in scope to allow of a full and complete report on the navigation of the river. They have come to the conclusion that the channel demanded by the owners of deep draught ships—that is, one having 30ft. at low water up to Gravesend—is, in the face of what has been done in other rivers, and especially at Southampton, a reasonable demand, and that such a channel would be of great public advantage, and that there is no serious difficulty in obtaining such a depth. But such a channel would be useless unless the river were also deepened between the Leigh Middle and Gravesend, where there now exist shoals with only 23ft. over them; but this forms no part of the programme of the Thames Conservancy, although, as the Commissioners remark, "it is highly important that all homeward-bound vessels should be able to reach, and foreign-going vessels able to leave, Gravesend at any time of the tide." Under present conditions, an inward or outward-bound vessel drawing 25ft., with an allowance of 2ft. under her keel, can pass the Leigh Middle shoals without delay at any state of the tide on about 125 days in the year, but she may be detained for want of water on 240 days. Vessels drawing 28ft. may have to wait every day of the year for periods ranging from a few minutes to 5¼ hours. The present aim of the Thames Conservancy, which they are attempting to accomplish by dredging, is to give 24ft. between Yantlet and Crayford Ness, a distance of 20¼ miles; 22ft. up to the Albert Dock, 6½ miles; and 18ft. to the Thames Tunnel and London Bridge, 9 miles.

The investigations of the Commissioners as to the deposit of dredgings by the Thames Conservancy in Dead Man's Hole have a very important bearing in connection with the enormous amount of sludge which is daily being discharged into Barrow Deep from the London Sewage Works. Since 1878 the Conservancy have deposited, in a deep three miles above the Leigh Middle shoals, over an area of 200,000 square yards, more than 2,000,000 cubic yards of dredgings. Recent surveys show that while other portions of the river have become shallower, the depth in Dead Man's Hole has not been reduced, and it follows that the solid matter deposited there has found its way into other parts of the river. Generally the result of the recent survey shows that the channels of the river Thames have improved since 1883.

Belfast and Dublin.—From the annual reports issued by the Commissioners of these ports, there appears to be a marked difference in their prosperity. While the income for last year at Belfast is the largest ever received, that at Dublin shows a considerable falling off. At Belfast the total receipts from all sources for the year was £139,190, an increase of £8255 on the previous year. The expenditure was £128,342, leaving a surplus of £10,848. During the present century the tonnage has increased from 5500 tons to 2,150,232 tons, the increase of 1895 over the previous year being 64,279 tons. The Commissioners have expended £226,267 in reclaiming land, part of which is now profitably used for shipbuilding yards, and part is intended for future extensions of the quays. Upwards of £200,000 has also been spent on graving docks. At Dublin the tonnage for last year was 1,796,071 tons, or 62,398 tons less than in the previous year—almost the same quantity that Belfast has gained. The continental and oversea shipping shows a decline of 41,954 tons, and the coasting and general cross channel trade of 13,594 tons. Steam colliers decreased by 5967 tons, and sailing colliers 3127 tons. The receipts amounted to £54,644, being a decrease on the previous year of £2710. The dredging of the channel has been continued, 432,210 tons of material having been removed. One of the hoisting dredgers is to be converted into a suction dredger at a cost of £10,050.

Peterhead.—From the last report issued it appears that this harbour of refuge is progressing but slowly. It is now ten years since the Act sanctioning the work was passed, and it was then expected that the work would take from twenty to thirty years to complete. As it is intended that the convict labour shall be utilised in the construction of this harbour, a great number of preliminary arrangements had to be made before the actual work of construction could be commenced. A prison had to be erected for the reception of the convicts, and accommodation for the officials and warders; workshops and stores were required; and a line of railway for conveying the stone from the quarry at Stirling-hill. These works were not completed until 1888, when the first batch of convicts was received into the prison. Until recently the number of convicts has been limited, and the progress of the work slow. During last year the south breakwater has been extended 90ft., and the foundation of a further length of 66ft. prepared and levelled with concrete. The whole of this work under water has been done by divers. A barge harbour has also been made. The length of the breakwater, allowing for the opening, is to be 3600ft., and at the present rate of progress it will take thirty years to complete. The cost was estimated by Sir John Coode at £750,000. The annual grant is £25,000. The breakwater consists of a wall built of concrete blocks, weighing from 27 tons to 50 tons each, faced with granite, and resting on a rubble base of granite. The water area of the harbour will be about 400 acres, and the walls will extend into a depth of from 70ft. to 80ft.

Ipswich.—The Commissioners of this port having come to the conclusion that the present dredging plant is obsolete and not equal to the requirements for further deepening the river, have determined to spend £20,000 in the purchase of new plant. It is intended to obtain a stationary dredger, capable of raising 400 tons an hour and of dredging to a depth of 28ft.; also two steam hoppers each capable of conveying 400 tons to sea at a speed of nine knots, the distance being fourteen miles. The depth to which it is intended to dredge the channel is 24ft. at high water neap tides.

Yarmouth.—It is intended to improve the entrance to this harbour by an extension of the concrete works at the North Pier at Gorleston, and the creation of a "spending beach," in order to reduce the effect of the waves entering between the piers, which have proved to be very injurious to the fishing vessels during gales, especially to those which are moored at Gorleston. The estimated cost is £20,000, and the scheme has been adopted on the recommendation of Messrs. Coode, Son, and Matthews, the consulting engineers of the Commissioners.

Birmingham Canal navigations.—The annual report of the directors of these navigations shows that during last year there was a decrease in the receipts for tonnage and wharfage, chiefly attributable to the revision made by the Board of Trade under the Canal Tolls and Charges Act, and especially to the effect of that measure on the coal traffic through Birmingham, and partly to the severe frost of the winter of 1894-5. The balance available for dividend was £9725, the difference in amount required to make up the 4 per cent. guaranteed by the London and North-Western Railway being £39,065.

The scheme for improving the means of canal communication between Wolverhampton and Birmingham and London, which was brought forward two or three years ago, was revived at the recent meeting of the South Staffordshire Institute of Iron and Steelworkers by Mr. A. M. Punnett, as a means of enabling merchants to meet the competition of Germany and Belgium. The Committee who investigated this matter at the time, when the scheme was first brought forward, estimated the traffic between Wolverhampton and London as three times as much as that to Liverpool, and seven times as great as that to Bristol. They, therefore, advised the improvement of the Grand Junction Canal, the estimated cost being £1,250,000, and the benefit to be derived a reduction in carriage on iron of from 12s. 6d. to 6s. a ton, and on coal of from 6s. 9d. to 4s. It will be remembered by the readers of this journal that at the meeting of the Federated Institution of Mining Engineers held last year at Birmingham the question of a better water communication between this town and the seaports was discussed, and papers read by Mr. Wells, Mr. Wheeler, Mr. Vernon Harcourt, Mr. Marten, and others, from which it appeared that the opinion of these engineers was to the effect that the Severn is the natural seaport of Birmingham, and that the scheme of Mr. Keeling for improving the canals between Birmingham and the Severn offered the greatest advantages at the smallest cost. By this means a canal system affording accommodation to steamboats of 300 tons, and capable of coast navigation, would give to Birmingham sea communication with Bristol, Cardiff, Swansea, and the other Severn seaports; and also by the sea route with Liverpool, the Thames, and with Rouen, Paris, Antwerp, and other continental ports. The estimated cost of this scheme is £600,000, or about half that of improving the Grand Junction.

Sheffield and South Yorkshire Navigation.—The report of the directors of this company for the ten months to the end of last year shows a balance of revenue of £27,243, which, after paying debenture and preference interests at the rate of 4½ per cent., left £3569, sufficient to pay ½ per cent. on the ordinary shares. The tonnage for the ten months was 738,835, and tolls £43,639. The average for the same period between 1888-92 was—tonnage 704,776, tolls £43,240, showing a slight increase. The reason of the increase of the tolls not being proportionate to the increase in the tonnage is due to reduction imposed by the Board of Trade under the orders of the Canal Traffic Act. Beyond building a new warehouse at Sheffield and improving the accommodation there, the directors do not appear to have carried out any of the works contemplated when the Act was obtained for enlarging the locks and improving and deepening the canal so as to adapt it for a proper service of steam barges and coal-conveying compartments similar to those on the Aire and Calder. Until this is done, and a better sea communication made by the proposed junction with the Aire and Calder, so as to get an opening to Goole Docks, it cannot be expected that there will be much increase in the traffic. It is stated that Messrs. France and Co. intend to commence a service of steam barges between Sheffield and Goole, and that it is intended to dredge the river Don and Dutch river from Stainforth to Goole, for the purpose of providing a better waterway pending the construction of the new Junction Canal.

THE NORTH POLE BALLOON.

FROM the earliest classic times attempts have been made in the most persevering, if in a somewhat unpractical manner, to accomplish the transit from one point of the globe to another by an aërial instead of a terrestrial or a combined land and water route. So far as the two latter routes are concerned, the most recent desirable result, that of reaching the North Pole, has not hitherto been attained, and it is exceedingly doubtful whether it ever will be. Reverting for the moment to the old four elements, and omitting all consideration, for obvious reasons, of one of them, we are reduced to three, two of which, as already stated, have signally failed in their meritorious and heroic endeavours. There remains the third, which M. S. A. Andrée intends shortly to attempt, and for the expedition a North Pole balloon is at present being constructed in France, an expedition which is very naturally exciting a considerable amount of attention throughout the whole civilised world.

A brief description of the general features of this polar balloon will probably be interesting to our readers. It may be premised that the balloon will not be so large as several that have already made their appearance in public. For instance, a captive balloon the sole object of which is to transport people into the air for a very short period, and then to bring them safely back to *terra firma*, should be of as large a diameter as would be consistent with the financial proportions of outlay and receipts. The balloon of M. Andrée is intended for a very different purpose. Its object is to solve a problem, to make a discovery which has hitherto baffled, with lamentable results, the attempts of numerous able, skilful, and experienced navigators. It is not, therefore, intended to carry more people in it than are considered necessary to elucidate the great question at issue. Thus, the balloon will be of moderate size and the more easily managed. The unmanageableness of a balloon, as we have reason to know, increases enormously in proportion to its diameter.

The North Pole balloon has a diameter of 67ft. and a volume of 162,396 cubic feet. It has been decided, states our contemporary *L'Aérophile*, that the Chinese pongee silk—a material well known to Anglo-Indians—possesses superior claims to all other materials for the construction of the balloon. Two other descriptions of silk are to be employed in rotation, failing a sufficient supply of the pongee, which is classed as A1, and will stand a tensile stress of two tons to the square inch. If we divide the balloon horizontally by a great circle, we obtain its equator, and above this zone there will be three thicknesses of silk, and below it only two. In a word, north latitude and south latitude are in the proportion of three to two.

It may just be possible that when a balloon sets out in search of the South Pole these *pièces de resistance* may, so far as thickness is concerned, be reversed. From the northern or upper portion of the balloon to about 10ft. below its equator the skin will be in folds of triple silk, which is a very different substance from the Horatian "æs triplex." Below this parallel the silk will be only in double folds. All joints in the silken envelope will be first glued or sized, and then sewn together and covered with external and internal wrappers about 1¾ft. in width, very much after the fashion of iron bars and plates, with double-cover plates. Silken thread will be used for stitching the joints, and the skin moreover will be strengthened at the top and bottom rings and around all openings such as man-holes, port-holes, and wherever valves are located, and skylights. The weight of the balloon without fittings is almost exactly one ton, and before it is varnished, either inside or outside, it will be tested with an internal pressure equal to 3in. of water. Italian hemp of the best quality has been selected for the network, having a minimum breaking tensile strength of between seven and eight tons.

Accommodation for the intrepid *voyageurs* will be provided in the car, which has a diameter of 6½ft. and a depth of 4¼ft., and is constructed of wicker work. Hempen cords, six in number, 9ft. in length, and 1·2in. in diameter, will suspend the car from the body of the balloon. These suspension cords will be interlaced or braced together by horizontal and diagonal cords, so as to form a very efficient parapet or protection to the occupants of the car. A certain amount of ballast, although only so much deadweight, must be carried in all aërial excursions. The number of bags considered sufficient to suffice for the polar expedition of M. Andrée is estimated at 175. All are made up of hemp and filled with sand, and their total weight amounts to 2975 lb. It appears that the contract for the construction of the balloon has been placed in the hands of M. Henri Lachambre, an experienced aëronautical engineer, for the sum of £2100. It has been erroneously stated in several publications that the car of the balloon was pierced in the roof to allow of the passage of the guide ropes. Such an arrangement would be a serious infringement of the rules of aërial navigation. On the contrary, the guide ropes will be attached to the belt or zone of the balloon itself, while the car will be suspended in such a manner that the shocks or jerks occasioned by the trailing of the guide ropes will be nullified as much as possible. In the floor of the car there will be an aperture through which the light and heat of a lamp will pass, for the double purpose of warming the aëronauts and their food also. While alight the lamp will be, as a matter of precaution, suspended outside the car. There will be three guide ropes of the respective lengths of 1155ft., 1320ft., and 1485ft., and weighing in all one ton. They will be made of cocoanut fibre, in sections of alternate strength and weakness, in order that they should separate and give way if they fouled any obstruction which they could not clear. Experiments, conducted to determine the coefficient of friction for the guide ropes, give one-sixth for ordinary circumstances and conditions, but on ice the friction becomes reduced to one-half of this amount. It may be mentioned that a pigeon cot or pigeon house has been built at Hammerfest, the most northern village in Europe. Several pigeons "raised" in this house are to accompany M. Andrée and his intrepid friends in their polar expedition.

INSTITUTION OF NAVAL ARCHITECTS.

THE summer meetings of the Institution will be held this year in Hamburg on Monday, June 8th, and the following day.

On Wednesday, June 10th, the meetings will be transferred to Berlin, on the invitation of the Imperial German Government, and will continue there during the remainder of the week.

On Monday, June 15th, the Vulcan Company, of Stettin, will be happy to receive any members of the Institution who can spare the time to visit their works. Stettin is only two and a-half hours by rail from Berlin, and a special train will be arranged to convey the members there and back. Two Transatlantic liners of the largest size, a cargo steamer larger than any other at present in existence, and a first-class cruiser for the German Government, are under construction at the Vulcan Company's works.

The Hamburg-American Company has generously offered to take the members over in a body from Tilbury to Hamburg in the twin-screw Transatlantic liner Fürst Bismarck—length 502ft.—free of charge. The steamer will start either late on Saturday night, June 6th, or else early on Sunday morning, June 7th, and will arrive in Hamburg in about twenty hours after her departure. A special train, of which particulars will be given in the detailed programme, will convey the members from London to the port of embarkation on the Saturday evening.

Full particulars of the papers to be read, of the works and places of interest to be visited, and of the excursions and entertainments which are being organised, will be forwarded to the members on or about the 23rd of May.

In the meantime the members will be pleased to know that the meetings are receiving the warmest support from the Imperial Government, under whose direction the arrangements at Berlin are being prepared. A programme of exceptional interest for the instruction and entertainment of the members is already in course of preparation.

The meetings for the reading and discussion of papers will be held in Hamburg, in the Bürgerschafts-Saal in the building of the Patriotische Gesellschaft, and in Berlin in the large hall of the Technical High School, which is a very fine room, and admirably adapted for the purposes of the Institution.

Papers have already been promised by the following German members of the Institution:—Herr Dietrich—Privy Councillor—Constructor-in-Chief of the Imperial German Navy; Herr F. Laeisz, President of the Chamber of Commerce of Hamburg; and by the following, amongst other home members of the Institution:—Mr. B. Martell, "On various Descriptions of Doors applicable to Water-tight Bulkheads and their Fastenings," &c.; Mr. F. Elgar, LL.D.

At Hamburg the members and ladies will be entertained at a garden party on Monday, June 8th. An inaugural meeting for the reading and discussion of papers will be held on the morning of Tuesday, June 9th. A visit will be paid to the shipbuilding establishment of Messrs. Blohm and Voss in the afternoon of that day, and in the evening the Hamburg Reception Committee will entertain the members and ladies at dinner at the picturesque resort Blankenäse, on the Elbe.

At Berlin active preparations are in progress of completion, and every possible step is being taken to render the visit of the members to the German capital both instructive and agreeable.

The members of the Institution will dine together on one of the evenings at the Kaiserhof Hotel, Berlin, at 7 o'clock. The hosts of the Institution at Hamburg and Berlin will be the guests of the Institution on that occasion. Tickets will be £1 each, wine included. The exact date will be announced in the programme.

The railways on both sides have been approached with the view to giving special reductions in the fares to members on their return home, and also to those members who cannot avail themselves of the Hamburg-American liner Fürst Bismarck.

The Council trust that the members of the Institution will do all in their power to assist in doing honour to their most hospitable hosts by attending in large numbers.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Assistant-engineers (temporary)—Walter W. Newton and Percy F. Griffiths, to the Victory; Henry George Radford and Albert John Venning, to the Vivid; George Herbert Fletcher and Cecil Edward Vinning, to the Pembroke, to date May 1st.

"THE ENGINEER." SWAIN ENG.

LIGHT RAILWAYS ABROAD.

No. II.

ROLLING STOCK.

SINCE the year 1885 the Société Nationale brought into use a number of different types of engines, as represented by Figs. A to I—page 439 and the supplement, and of which our tabular supplement gives the principal dimensions, in English measurements, corresponding with the dimensions on the engravings, which are given in the metric measures. The Société Nationale finds that, from all the different types in use, the engines weighing 15½ tons in full working order are those working most efficiently, and are strongly to be recommended for the ordinary general service; while for heavy freight trains, especially on hilly lines, the type of 27 tons in full working order are the best. The author had opportunity for travelling several times with these locomotives on the different lines, of which the engines of the Société Métallurgique of Brussels and of the Sociéte of St. Leonard of Liège well represent the above types—shown in Diagram A to I. In the first engines constructed by the Société Métallurgique some provision was made to condense the exhaust steam by leading it through condensing pipes fixed in one of the water tanks before passing it into the chimney, but, similar to the writer's experience with other engines, the water in the tank got rapidly very hot, and had, therefore, often to be changed, while the tank itself would have got exposed to injurious accumulation of grease from the waste steam, and if used again for feeding the boiler would have caused greasy deposits on the fire-box and boiler shell, and rapidly worked its destruction by burning the plates. This practice was, therefore, discontinued, and all that is done now in the engines of later construction is that a small cold water tank is placed between the two vessels, through which the exhaust steam passes before going into the chimney; there it is largely condensed, but the principal point of this arrangement is the reduction of the noise of the exhaust steam, and not for the purpose of condensation. The steam distribution in this engine is effected by the Walschaert system, so generally used on the Continent. The boiler is of iron; the tubes are of brass, without copper ends; while the fire-box, with its stays, are of copper, the crown stay bolts being of iron; the axles and the wheel flanges are of steel, while the nave and the spokes are of iron; the whole of the machinery is of fine grained or of Swedish iron; the axle bearings are of bronze, composed of 84 per cent. of copper and 16 per cent. of tin.

The engine is represented in fuller detail than in the diagrams, in Fig. 36, p. 441, which represents the elevation; Fig. 37, half sectional and half full view in plan; and Fig. 38, p. 445, half transverse section and half end view. Its principal dimensions will be seen from the diagram and table under Class A.

The engines shown by the type drawings in the supplemental engraving, marked A to I, and the outline dimension diagrams on page 439, correspondingly marked A to I, are illustrated in detail on pages 441 and 445.

The general type of engines as manufactured by the Société St. Leonard, at Liège, for 1 metre narrow-gauge lines is shown in Fig. 39, which is a side elevation; Fig. 40, a plan; and Fig. 41, half end view and half transverse section. Some modifications are, however, made in the general type of engines, as they are always particularly constructed according to the conditions of the line on which they have to work. They are outside-cylinder engines, and the frames are outside the wheels, to prevent as much as possible the side-sway of the engine. They have three axles, with the six wheels coupled. To preserve the requisite stability the centre of gravity is kept as low as possible, being lower than the height allowed for it on engines working on normal-gauge lines. The main connecting-rods—as shown in elevation and plan—are very long, as they are directly coupled to the crank pins of the hind axles by means of Hall's system. This system is greatly used in Austria and Bavaria. It seems to offer the advantage of reducing to a minimum the leverage of the overhang of the crank pins—measured in plan—by bringing the coupling rods closer to the wheels. The distribution of the weight over the axles is carefully made, so as to obtain the greatest adherence. To distribute the weight as regularly as possible over the coupled axles the wheel springs are connected with compensation levers or balanciers. The pistons are usually of Hadfield's cast steel, and the rods of Bessemer steel. The system of steam distribution in the cylinders is on the Walschaert principle, which, by variable expansion and with the reversing gear, offers the great advantage of giving the same lineal advance or lead of the slide valves for every degree of expansion.

Grate.—The grate is so arranged as to allow the burning of briquettes manufactured of coal dust—a fuel which, however, according to the author's experience, even in this type of engine, caused considerable smoke, to the great annoyance of the travelling public. The water tanks, from which the boiler is fed by means of Giffard injectors, are placed on both sides of the boiler. The engine is, however, also provided with an extra feed pump in case of need. The price of the engine is about 1·66f. per kilogramme, or about 11·32d. per pound of weight. Its principal dimensions, some of which are also marked on diagram Table A—I, under class C, are as follows:—

Diameter of cylinders	11in.
Stroke of pistons...	1ft. 2⅝in.
Diameter of wheels	2ft. 8¾in.
Wheel base	5ft. 10⅞in.
Length of fire-box	3ft. 4 7/16in.
Width of fire-box at top	3ft. 0¾in.
Width of fire-box at bottom	2ft. 3 11/16in.
Height of fire-box in front	3ft. 7 5/16in.
Height of fire-box at end...	3ft. 1in.
Diameter of barrel	3ft. 4 9/16in.
Total length of boiler	10ft. 4⅞in.
Length of tubes between tube-plates ...	5ft. 2¾in.
Diameter of tubes	1⅜in. to 1 9/16in.
Number of tubes	160
Grate surface	7·9 sq. ft.
Heating surface of fire-box	44·65 sq. ft.
Heating surface of tubes, inside	299·12 sq. ft.
Total heating surface	343·78 sq. ft.
Capacity of water tanks	444·4 gallons
Capacity of coal bunkers	1100 lb.
Weight of engine, empty...	15 tons, French
Weight of engine in full working order	18½ tons, French
Certified boiler pressure	10 atmospheres
Theoretical tractive power	7700 lb.
Effective tractive power at 60 per cent...	4620 lb.
Total length of engine to end of buffers	20ft. 2⅞in.
Outside width	8ft. 0¾in.
Height from rail surface to top of chimney	9ft. 11 7/16in.

It will also be remembered that the Société Nationale des Chemins de Fer Vicinaux recommended Class E for heavy work and hilly lines, of which class the St. Leonards works also supplied a great number of first-class engines, which gave great satisfaction, and which were specially recognised by the Société Nationale. This closes the record of the Belgian engines in this review, as used by the great and powerful Belgian Tramways Company, La Société Nationale, and of which the following general table A—I, in accordance with the corresponding diagrams, gives in full the practical and most important details of the series of engines in use on their lines.

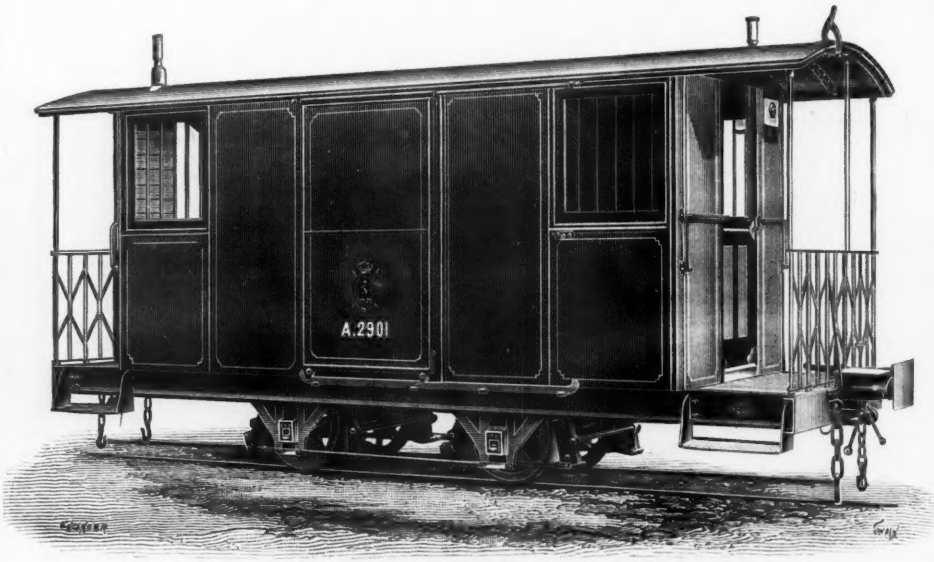

Fig. 53—LUGGAGE VAN

The locomotive works of Krauss and Company at Münich, in Bavaria—Germany—are amongst the most important manufacturing concerns on the Continent for tramway and narrow gauge railway locomotives. The writer thinks it will, therefore, be of great interest to bring before the reader for comparison a short description of the most recent of the types of engines manufactured by this company, the more so as this engine contains some very important and novel details which this company has patented. They consist in a new arrangement and disposition of the movable wheel or bogie frames, to allow locomotives of great or large wheel-base to pass through very sharp curves, without offering great resistance, nor to press too hard on the rails. The American bogies, or others already in use, are, as it is stated, very expensive arrangements, requiring frequent repairs, and the cost of maintenance is therefore very great. This is, of course, a very important point to consider in the present case of narrow gauge lines, where the cost of establishment is such a serious item, that on it depends whether the line can be made or not. Any economy in construction either of permanent way or rolling stock, which thus can be realised, without impairing the effectiveness of the service, is therefore of considerable advantage, and will have to be adopted on these lines. The engines actually used on narrow gauge lines have usually two or more coupled axles, with a movable bogie of two running axles fixed either in front or at the tail of the engine; these bogies pass the curves the easier the fewer the coupled axles there are on the engine. On light railways, however, it is not so much high speed but great tractive power which is wanted, consequently these engines often possess insufficient adhesion, as the bogie absorbs a large portion of the total weight of the engine somewhat out of proportion of the amount it should take; or, again, it occurs that, on the contrary, these engines have to be built far heavier than the tractive power to be obtained would require, and this because of the weight on the bogie. As stated, it has further to be considered that the locomotives which are provided with one radial axle, on whatever principle or system, do not answer the purpose sufficiently. Their adaptability to pass the curves well, and to return afterwards to their normal position in the axis of the permanent way, is not sufficiently secured to be always effected as completely as required. To avoid these defects, the present construction has been introduced. The adjoined table of diagrams—Figs. 42 to 50—represents the types of locomotives which were provided with the new arrangement and disposition of the movable frame of this construction. These engines were provided with free leading axles, but with a wheel base which did not correspond so well to the curves they had to pass. To remove these defects, and to avoid the use of the costly movable bogie with two free axles, the Krauss Company devised the new arrangement, namely, to form the bogie out of one of the coupled axles, and of one free axle only.

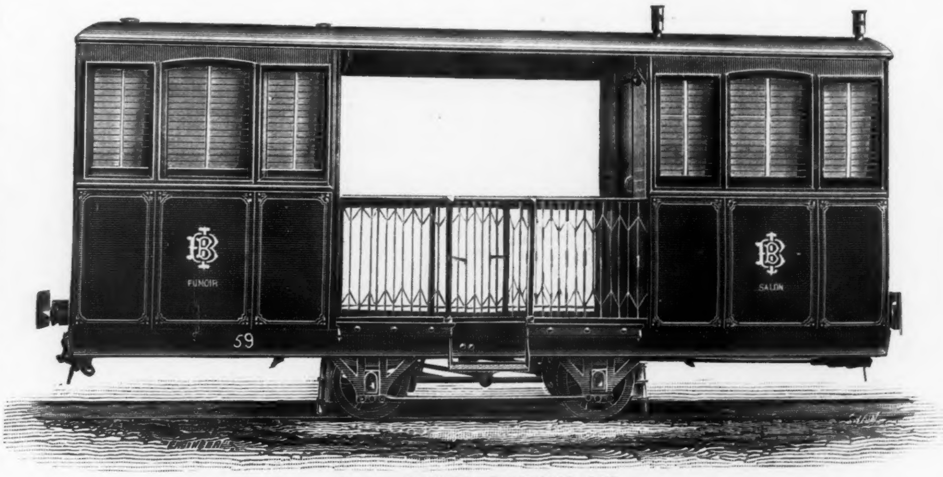

Fig. 59—CENTRAL PLATFORM CAR

To this effect a frame made of plate iron and the required angle irons, or made of cast steel, is fixed to the engine frame, on which it moves round a pivot, and connects the running axle with the next coupled axle of the engine, so that the latter turns in the curves in a direction at right angles to the longitudinal axis of the locomotive, while the free axle turns in the radial direction of the curve. The arrangement is indicated in the diagram. Both axle-boxes of the coupled axle are transversely connected together by the plate iron framing and to the bogie frame, by means of a ball-and-socket joint. The axle-boxes are also made so as to have some side way clearance in the horn plate guides; while at the same time the crank pins of the coupled axle are of ball-shaped form, to prevent any wedging of the connecting-rods. These pins do not show any unusual, but only a normal use in the joint. The axle-boxes of the free axle are independent of the main frame of the locomotive, and are fixed to the bogie frame. The transmission of the load upon the running axle takes place in the longitudinal axis of the locomotive by means of a transverse bearing spring and a corresponding vertical rod, which latter takes an inclined position during the passage of the free axle in the curve, and thus brings the bogie frame back to its normal position, after having left the curve. The engines represented on the diagram—Fig. 42 to Fig. 50—are used for main, secondary, and light railways, of normal or narrow gauge, and are in use on State and private lines, for express and ordinary trains, for passenger and goods traffic.

It is stated that these locomotives wherever they are used have satisfactorily answered all the requirements of the different railway companies. Their steadiness and stability on the straight line, as well as in passing the curves without slackening speed, in spite of their comparative lightness, has been well recognised. Comparing the arrangement of this movable bogie with engines provided with a radial axle, it will be found that this arrangement and disposition is simple, practical, and efficient for taking the curves and returning to the normal, and does not require any special construction to this effect. For light narrow gauge railways and with light permanent way, the tank engine, with three coupled and one trailing free axle, as represented in diagram, Fig. 42, and in detail in Figs. 51 and 52, is most suitable. This engine is built to different sizes, according to the local conditions of the line. The free axle and the third-coupled axle next to it, form the new movable bogie, turning round the point X. With this locomotive curves of the same minimum radius can be passed as with an ordinary locomotive of three-coupled axles of 1800 mm.—5ft. $10\frac{7}{8}$in.—wheel base. The running axle, however, permits the carriage of big water tanks and coal bunkers, as well as the use of a boiler with greater direct heating surface and fire-grate, without any overloading of the third-coupled axle. Besides there is another advantage, and that is of a large wheel base, producing a more steady run of the engine, and thus less wear and tear of the permanent way and the engine itself. The next important items, forming part of the rolling stock, are the vehicles for passenger and goods traffic, of which herewith follows the description.

CARS.

The vehicles for the Société Nationale des Chemins de Fer Vicinaux were mostly supplied, as far as the writer is informed, by the Société La Métallurgique mentioned before in reference to their supply of engines. The body of the cars with the framework is of teak, while the interior lining is of pitch pine. The outside of the car body is also covered with sheet iron of $1\frac{1}{4}$ mm., or about $\frac{3}{64}$in. thickness. The under frame carrying the body is of iron, the axles and wheel flanges are of steel, the naves and spokes of forged iron, worked under the steam hammer. The seats of the second-class carriages, which are the carriages mostly used by the travelling public, are alternately of laths of pitch pine and teak. The first-class carriages are mostly in all respects similar as to general construction, but are provided for seats and backs with velvet cushions stuffed with horsehair. The total length of the cars, as will be seen from Fig. 53, a longitudinal elevation of a second-class car, is 7·280 m. (23ft. $10\frac{9}{16}$in.), inclusive of buffers, while the outside width, as shown—plan, Fig. 54, and in the end elevation, Fig. 55—is 2·320 m. (7ft. $7\frac{1}{4}$in.), exclusive of roof. There are twenty-four seats inside, with standing room for sixteen passengers on the two platforms. The seats are cross benches, with a longitudinal passage in the centre of the car between them. In the first-class carriages there is, however, one compartment provided with a couch going lengthways, one each side, as shown in plan, Fig. 56. All the principal dimensions will be seen in the above mentioned figures. Besides the first and second-class carriages, there are also mixed carriages, with first and second-class compartments in one carriage, as represented in plan Fig. 57. The luggage van, as used on these vicinal lines, is shown in Fig. 58, from a photograph, which in case of need can also be used as a passenger car, being in its general dispositions of the same type. Its total length, inclusive of buffer, is 6·294 m. (20ft. $7\frac{3}{4}$in), and its total width 2·400 m. (7ft. $10\frac{7}{16}$in.).

According to the experience of the writer, who frequently travelled in the different classes of these cars in fine, as well as in rainy and stormy weather, they are very satisfactory, well adapted and thoroughly efficient for this kind of service. They are, on the whole, of elegant design, comfortable, for the comparatively short journeys, and neatly built. The platforms make the travelling in fine weather more pleasant, with the exception of the annoyance of smoke coming from the engine, especially as coal dust briquettes are used on the country lines, coke only being used in the towns. The centre passage of the cars is essentially for the guard, who collects fares, and, when need be, sells tickets; the latter only in exceptional cases. For his protection, a small foot-plate covers part of the buffers, hook and chain connection, as seen in Fig. 58, and thus gives him free passage through the whole train. The doors are mostly left open by the public, with the result that the smoke fills the cars, an annoyance which should, and the writer thinks could, easily be removed, by using coal briquettes and coke combined on the country road. Perhaps better stoking and closing some of the doors might be more effective.

As there is usually a heavy wind blowing over the country from the North Sea, and to better protect the traveller on the platform from rain and dust, the Société Métallurgique have introduced a new type of cars, with a central platform in the middle of the car, having the compartments at each end—as represented in engraving from a photograph, Fig. 59. Each of the compartments can be arranged for first or second class, or as saloon or smoking compartment. Each of the compartments contains six seats; the centre platform has standing room for twenty-four passengers. The total length of the car is 7·340 m. (24ft. 1in.), and the total width is 2·200 m. (7ft. $2\frac{3}{16}$in.), otherwise the car is of the same type as the other, constructed on the same principle, and the same material as for the other cars is used. The cars, on the whole, run steadily on the straight line, as well as on the curves. The writer did not observe any grinding in passing the latter; but, the material being comparatively light, some swaying of the cars occurs naturally when leaving the curves at ordinary, and not slackened, speed. The Société Nationale des Chemins de Fer Vicinaux finds, from its long experience with these cars, that the best types of passenger cars for their lines are the first-class carriages, the mixed carriages with first and second-class, and the second-class carriages, with two axles of 2·400 m. (7ft. $10\frac{7}{16}$in.) wheel base and of small capacity, as represented in Figs. 53 to 57. The luggage van, as shown in Fig. 58, is provided with a screw brake of eight brake-blocks.

As the construction of light railways is at present occupying such prominence, the few notes on the subject contained in these articles may be of some practical interest and value, and the writer thanks M. de Burlet, engineer-in-chief and managing director of the Société Nationale des Chemins de Fer Vicinaux, at Brussels, and the manufacturers herein named, who were kind enough to place the necessary information at his disposal.

As to the rolling stock of large capacity, the Société Nationale is waiting still more experience before pro-

A PIECE-RATE SYSTEM.*

(*Concluded from page* 418.)

(58) THE exact percentage beyond the usual standard which must be paid to induce men to work to their maximum, varies with different trades and with different sections of the country. And there are places in the United States where the men, generally speaking, are so lazy and demoralised that no sufficient inducement can be offered to make them do a full day's work.

(59) It is not, however, sufficient that each workman's ambition should be aroused by the prospect of larger pay at the end of even a comparatively short period of time. The stimulus to maximum exertion should be a daily one. This involves such vigorous and rapid inspection and returns as to enable each workman in most cases to know each day the exact result of his previous day's work, *i.e.*, whether he has succeeded in earning his maximum pay, and exactly what his losses are for careless or defective work. Two-thirds of the moral effect, either of a reward or penalty, is lost by even a short postponement.

(60) It will again be noted that the differential rate system forces this condition both upon the management and the workmen, since the men, while working under it, are above all anxious to know at the earliest possible moment whether they have earned their high rate or not. And it is equally important for the management to know whether the work has been properly done.

(61) As far as possible each man's work should be inspected and measured separately, and his pay and losses should depend upon his individual efforts alone. It is, of course, a necessity that much of the work of manufacturing—such, for instance, as running roll-trains, hammers, or paper machines—should be done by gangs of men who co-operate to turn out a common product, and that each gang of men should be paid a definite price for the work turned out, just as if they were a single man. In the distribution of the earnings of a gang among its members, the percentage which each man receives should, however, depend not only upon the kind of work which each man performs, but upon the accuracy and energy with which he fills his position. In this way the personal ambition of each of a gang of men may be given its proper scope.

(62) Again, we find the differential rate acting as a most powerful lever to force each man in a gang of workmen to do his best; since if, through the carelessness or laziness of any one man, the gang fails to earn its high rate, the drone will surely be obliged by his companions to do his best the next time or else get out.

(63) A great advantage of the differential rate system is that it quickly drives away all inferior workmen, and attracts the men best suited to the class of work to which it is applied, since none but really good men can work fast enough and accurately enough to earn the high rate; and the low rate should be made so small as to be unattractive even to an inferior man.

(64) If for no other reason than that it secures to an establishment a quick and active set of workmen, the differential rate is a valuable aid, since men are largely creatures of habit; and if the piece-workers of a place are forced to move quickly and work hard the day-workers soon get into the same way, and the whole shop takes on a more rapid pace.

(65) The greatest advantage, however, of the differential rate piece-work, in connection with a proper rate-fixing department, is that together they produce the proper mental attitude on the part of the men and the management toward each other. In place of the indolence and indifference which characterise the workmen of many day-work establishments, and to a considerable extent also their employers; and in place of the constant watchfulness, suspicion, and even antagonism with which too frequently the men and the management regard each other under the ordinary piece-work plan, both sides soon appreciate the fact that with the differential rate it is their common interest to co-operate to the fullest extent, and to devote every energy to turning out daily the largest possible output. This common interest quickly replaces antagonism, and establishes a most friendly feeling.

(66) Of the two devices for increasing the output of a shop, the differential rate and the scientific rate-fixing department, the latter is by far the more important. The differential rate is invaluable at the start, as a means of convincing men that the management is in earnest in its intention of paying a premium for hard work; and it at all times furnishes the best means of maintaining the top notch of production; but when, through its application, the men and the management have come to appreciate the mutual benefit of harmonious co-operation and respect for each other's rights, it ceases to be an absolute necessity. On the other hand, the rate-fixing department, for an establishment doing a large variety of work, becomes absolutely indispensable. The longer it is in operation the more necessary it becomes.

(67) Practically the greatest need felt in an establishment wishing to start a rate-fixing department is the lack of data as to the proper rate of speed at which work should be done. There are hundreds of operations which are common to most large establishments; yet each concern studies the speed problem for itself, and days of labour are wasted in what should be settled once for all, and recorded in a form which is available to all manufacturers.

(68) What is needed is a handbook on the speed with which work can be done, similar to the elementary engineering handbooks. And the writer ventures to predict that such a book will before long be forthcoming. Such a book should describe the best method of making, recording, tabulating, and indexing time-observations, since much time and effort are wasted by the adoption of inferior methods.

(69) The term "rate-fixing department" has rather a formidable sound. In fact, however, that department should consist in most establishments of one man, who in many cases need give only a part of his time to the work.

(70) When the manufacturing operations are uniform in character, and repeat themselves day after day—as, for instance, in paper or pulp mills—the whole work of the place can be put upon piece-work in a comparatively short time; and when once proper rates are fixed, the rate-fixing department can be dispensed with, at any rate until some new line of manufacture is taken up.

(71) The system of differential rates was first applied by the writer to a part of the work in the machine shop of the Midvale Steel Company in 1884. Its effect in increasing and then maintaining the output of each machine to which it was applied was almost immediate, and so remarkable that it soon came into high favour with both the men and the management. It was gradually applied to a great part of the work of the establishment, with the result, in combination with the rate-fixing department, of doubling and in many cases of trebling the output, and at the same time increasing instead of diminishing the accuracy of the work.

(72) In some cases it was applied by the rate-fixing department without an elementary analysis of the time required to do the work; simply offering a higher price per piece providing the maximum output before attained was increased to a given extent. Even this system met with success, although it is by no means correct, since there is no certainty that the reward is in just proportion to the efforts of the workmen.

(73) In cases where large and expensive machines are used, such as paper machines, steam hammers, or rolling mills, in which a large output is dependent upon the severe manual labour as well as the skill of the workmen—while the chief cost of production lies in the expense of running the machines rather than in the wages paid—it has been found of great advantage to establish two or three differential rates, offering a higher and higher price per piece or per ton as the maximum possible output is approached.

(74) As before stated, not the least of the benefits of elementary rate-fixing are the indirect results. The careful study of the capabilities of the machines, and the analysis of the speeds at which they must run, before differential rates can be fixed, which will ensure their maximum output, almost invariably result in first indicating and then correcting the defects in their design and in the method of running and caring for them.

(75) In the case of the Midvale Steel Company, to which I have already referred, the machine shop was equipped with standard tools furnished by the best makers, and the study of these machines, such as lathes, planers, boring mills, &c., which was made in fixing rates, developed the fact that they were none of them designed and speeded so as to cut steel to the best advantage. As a result, this company has demanded alterations from the standard in almost every machine which they have bought during the past eight years. They have themselves been obliged to superintend the design of many special tools which would not have been thought of had it not been for elementary rate-fixing.

(76) But what is perhaps of more importance still, the rate-fixing department has shown the necessity of careful systematising all of the small details in the running of each shop; such as the care of belting, the proper shape for cutting tools, and the dressing, grinding, and issuing same, oiling machines, issuing orders for work, obtaining accurate labour and material returns, and a host of other minor methods and processes. These details, which are usually regarded as of comparatively small importance, and many of which are left to the individual judgment of the foreman and workmen, are shown by the rate-fixing department to be of paramount importance in obtaining the maximum output, and to require the most careful and systematic study and attention in order to ensure uniformity and a fair and equal chance for each workman. Without this preliminary study and systematising of details it is impossible to apply successfully the differential rate in most establishments.

(77) As before stated, the success of this system of piece-work depends fundamentally upon the possibility of materially increasing the output per man and per machine, providing the proper man be found for each job and the proper incentive be offered to him.

(78) As an illustration of the difference between what ought to be done by a workman well suited to his job, and what is generally done, I will mention a single class of work, performed in almost every establishment in the country. In shovelling coal from a car over the side on to a pile one man should unload forty tons per day, and keep it up, year in and year out, and thrive under it. With this knowledge of the possibilities I have never failed to find men who were glad to work at this speed for from four and a-half to five cents per ton. The average speed for unloading coal in most places, however, is nearer fifteen than forty tons per day. In securing the above rate of speed it must be clearly understood that the problem is not how to force men to work harder or longer hours than their health will permanently allow; but, rather, first, to select among the labourers which are to be found in every community the men who are physically able to work permanently at that job, and at the speed mentioned, without damage to their health, and who are mentally sufficiently inert to be satisfied with the monotony of the work, and then to offer them such inducements as will make them happy and contented in doing so.

(79) The first case in which a differential rate was applied furnishes a good illustration of what can be accomplished by it. A standard steel forging, many thousands of which are used each year, had for several years been turned at the rate of from four to five per day under the ordinary system of piece-work, 50 cents per piece being the price paid for the work. After analysing the job and determining the shortest time required to do each of the elementary operations of which it was composed, and then summing up the total, the writer became convinced that it was possible to turn ten pieces a day. To finish the forgings at this rate, however, the machinists were obliged to work at their maximum pace from morning to night, and the lathes were run as fast as the tools would allow, and under a heavy feed. It will be appreciated that this was a big day's work, both for men and machines, when it is understood that it involved removing, with a single 16in. lathe, having two saddles, an average of more than 800 lb. of steel chips in ten hours. In place of the 50-cent rate that they had been paid before, they were given 35 cents per piece when they turned them at the speed of ten per day, and when they produced less than ten, they received only 25 cents per piece.

(80) It took considerable trouble to induce the men to turn at this high speed, since they did not at first fully appreciate that it was the intention of the firm to allow them to earn permanently at the rate of 3·50 dols. per day. But from the day they first turned ten pieces to the present time, a period of more than ten years, the men who understood their work have scarcely failed a single day to turn at this rate. Throughout that time, until the beginning of the recent fall in the scale of wages throughout the country, the rate was not cut.

(81) During this whole period the competitors of the company never succeeded in averaging over half of this production per lathe, although they knew and even saw what was being done at Midvale. They, however, did not allow their men to earn over from 2 dols. to 2·50 dols. per day, and so never even approached the maximum output.

(82) The following table will show the economy of paying high wages under the differential rate in doing the above job:—

Cost of Production per Lathe per Day.

Ordinary system of piece-work.	Dols.	Differential rate system.	Dols.
Man's wages	2 50	Man's wages	3 50
Machine cost	3 37	Machine cost	3 37
Total cost per day	5 87	Total cost per day	6 87
Five pieces produced.		Ten pieces produced	
Cost per piece	1 17	Cost per piece	0 69

The above result was mostly, though not entirely, due to the differential rate. The superior system of managing all of the small details of the shop counted for considerable.

(83) There has never been a strike by men working under differential rates, although these rates have been applied at the Midvale Steel Works for the past ten years; and the steel business has proved during this period the most fruitful field for labour organisations and strikes. And this notwithstanding, the Midvale Company has never prevented its men from joining any labour organisation. All of the best men in the company saw clearly that the success of a labour organisation meant the lowering of their wages, in order that the inferior men might earn more, and, of course, could not be persuaded to join.

(84) I attribute a great part of this success in avoiding strikes to the high wages which the best men were able to earn with the differential rates, and to the pleasant feeling fostered by this system; but this is by no means the whole cause. It has for years been the policy of that company to stimulate the personal ambition of every man in their employ, by promoting them either in wages or position whenever they deserved it and the opportunity came. A careful record has been kept of each man's good points as well as his shortcomings, and one of the principal duties of each foreman was to make this careful study of his men, so that substantial justice could be done to each. When men throughout an establishment are paid varying rates of day-work wages, according to their individual worth, some being above and some below the average, it cannot be for the interest of those receiving high pay to join a union with the cheap men.

(85) No system of management, however good, should be applied in a wooden way. The proper personal relations should always be maintained between the employers and men; and even the prejudices of the workmen should be considered in dealing with them. The employer who goes through his works with kid gloves on, and is never known to dirty his hands or clothes, and who either talks to his men in a condescending or patronising way, or else not at all, has no chance whatever of ascertaining their real thoughts or feelings.

(86) Above all is it desirable that men should be talked to on their own level by those who are over them. Each man should be encouraged to discuss any trouble which he may have, either in the works or outside, with those over him. Men would far rather even be blamed by their bosses, especially if the "tearing out" has a touch of human nature and feeling in it, than to be passed by day after day without a word, and with no more notice than if they were part of the machinery. The opportunity which each man should have of airing his mind freely, and having it out with his employers, is a safety valve; and if the superintendents are reasonable men, and listen to and treat with respect what their men have to say, there is absolutely no reason for labour unions and strikes.

(87) It is not the large charities, however generous they may be, that are needed or appreciated by workmen, such as the founding of libraries and starting working men's clubs, so much as small acts of personal kindness and sympathy, which establish a bond of friendly feeling between them and their employers.

(88) The moral effect of the writer's system on the men is marked. The feeling that substantial justice is being done them renders them on the whole much more manly, straightforward, and truthful. They work more cheerfully, and are more obliging to one another and their employers. They are not soured, as under the old system, by brooding over the injustice done them, and their spare minutes are not spent to the same extent in criticising their employers. A noted French engineer and steel manufacturer, who recently spent several weeks in the works of the Midvale Company in introducing a new branch of manufacture, stated before leaving that the one thing which had impressed him as most unusual and remarkable about the place was the fact that not only the foremen, but the workmen, were expected to, and did in the main, tell the truth in case of any blunder or carelessness, even when they had to suffer from it themselves.

(89) From what the writer has said, he is afraid that many readers may gain the impression that he regards elementary rate-fixing and the differential rate as a sort of panacea for all human ills. This is, however, far from the case. While he regards the possibilities of these methods as great, he is of the opinion, on the contrary, that this system of management will be adopted by but few establishments, in the near future at least, since its really successful application not only involves a thorough organisation, but requires the machinery and tools throughout the place to be kept in such good repair that it will be possible for the workmen each day to produce their maximum output. But few manufacturers will care to go to this trouble until they are forced to.

(90) It is his opinion that the most successful manufacturers—those who are always ready to adopt the best machinery and methods when they see them—will gradually avail themselves of the benefits of scientific rate-fixing; and that competition will compel the others to follow slowly in the same direction.

(91) Even if all of the manufacturers in the country who are competing in the same line of business were to adopt these methods, they could still well afford to pay the high rate of wages demanded by the differential rate, and necessary to induce men to work fast, since it is a well recognised fact the world over that the highest-priced labour, providing it is proportionately productive, is the cheapest; and the low cost at which they could produce their goods would enable them to sell in foreign markets and still pay high wages.

(92) The writer is far from taking the view held by many manufacturers that labour unions are an almost unmitigated detriment to those who join them, as well as to employers and the general public. The labour unions—particularly the trades unions of England—have rendered a great service not only to their members, but to the world, in shortening the hours of labour, and in modifying the hardships and improving the conditions of wage-workers. In the writer's judgment the system of treating with labour unions would seem to occupy a middle position among the various methods of adjusting the relations between employers and men. When employers herd their men together in classes, pay all of each class the same wages, and offer none of them any inducements to work harder or do better than the average, the only remedy for the men lies in combination; and frequently the only possible answer to encroachments on the part of their employers is a strike. This state of affairs is far from satisfactory to either employers or men, and the writer believes the system of regulating the wages and conditions of employment of whole classes of men by conference and agreement between the leaders, unions, and manufacturers to be vastly inferior, both in its moral effect on the men, and on the material interests of both parties, to the plan of stimulating each workman's ambition by paying him according to his individual worth, and without limiting him to the rate of work or pay of the average of his class.

(93) The level of the great mass of the world's labour has been, and must continue to be, regulated by causes so many and so complex as to be at best but dimly recognised. The utmost effect of any system, whether of management, social combination, or legislation, can be but to raise a small ripple or wave of prosperity above the surrounding level, and the greatest hope of the writer is that, here and there, a few workmen, with their employers, may be helped, through this system, toward the crest of the wave.

THE Clyde shipbuilding industry is now fairly in the thick of a period of activity such as it has not experienced for a number of years. During the month just ended new shipping to the extent of approaching 40,000 tons has been launched, while during the same period no less than 52,000 tons have been ordered, including 2000 tons of Government work. This is some 9000 tons in excess of the tonnage booked during March, and quite 12,000 tons ahead of the bookings for February. Nor does the boom which this represents seem to have spent itself, as the flow of fresh orders continues, and quite a number of inquiries are in the market. The North German Lloyd Company is asking tenders for the construction of as many as five new steamers, each of 5000 tons, for the Brazil trade. As German yards have an abnormal quantity of tonnage on hand at present—of which 50,000 tons is to the order of this one company alone—it is very probable that several, if not all the five boats, will be built in this country, the Clyde, in all likelihood, coming in as usual for a big share of the work. Other three cargo vessels, ranging between 5000 and 6000 tons, are likely to be ordered within the next week or so from Clyde builders.

ROYAL UNITED SERVICE INSTITUTION.

STEADY PLATFORMS AT SEA FOR SEARCH LIGHTS.

AT the Royal United Service Institution on Wednesday, April 29th, Admiral Henry Boys, R.N., in the chair, a paper was read by Mr. Beauchamp Tower, M.I.C.E., on "An Apparatus for Providing a Steady Platform at Sea for Search Lights, &c."

In this apparatus, which has already been very fully described in our columns, the platform or part to be kept steady, and to which the search light is attached, is hung in gimbals, so as to have angular freedom in every direction, in the same manner as the bowl of a mariner's compass. A gyroscope is provided, revolving in a horizontal plane and throwing a truly vertical jet out of the axial jet nozzle. The directing of this jet in the true vertical is the sole business of the gyroscope and the only object of its existence. Immediately above the axial jet, and about ¼in. from it, are four open-mouthed ports formed in a circle, divided by radial divisions into four equal sectors; their open mouths are directed downwards towards the axial jet. The passages, of which they form the terminations, communicate each to one of the four cylinders. If the platform is truly horizontal, the axis of the axial jet passes through the centre of the circle containing the four ports, and the jet is equally distributed between them, but should the platform be the least bit out of the horizontal plane, some of the ports receive more of the jet than others, and this causes an inequality of pressure in the cylinders which cants the platform into the horizontal plane. Thus the vertical axial jet playing on the four ports acts as a force tending to keep the ports and itself concentric, and consequently the platform horizontal. The reason for using the jet as a connection between the gyroscope and platform is that it enables the gyroscope to powerfully control the platform, and yet suffer no reaction on itself. A very small force would be sufficient to disturb the gyroscope from its horizontal plane of rotation, but no force can be communicated to it from the platform, as it makes no difference to the gyroscope what the axial jet strikes against after it has left the nozzle. The water from the jets, after expending its energy in the manner described, falls past the gyroscope through the open bottom of the cell into the tank below, and thence through a pipe returns to the sea.

The first practical machine was fitted up on a small steam yacht, 50ft. long and 11ft. beam, and subjected to a laborious course of experiment, extending over about two years. It was experimented with by the officers of H.M.S. Vernon as a means of mounting search lights, and by the officers of H.M.S. Excellent as a means of mounting machine-guns. In both cases their reports showed that the machine answered the purpose for which it was designed perfectly, and I believe, so far as I am permitted to know, that their opinions were favourable. After these experiments, a machine for mounting a 24in. search light projector was ordered by the Admiralty to be fitted to H.M. gunboat Bloodhound, tender to H.M.S. Vernon, for further experiment, which showed that the machine could be depended on to keep a search light ray absolutely steady on a small vessel in a heavy sea, and I believe that further favourable reports were sent to the Admiralty on the subject. Since then, Sir W. G. Armstrong, Mitchell, and Co., have taken up the manufacture of these machines, and are fitting it to the torpedo destroyers Swordfish and Spitfire, which they are constructing for the Navy. They are also supplying these machines to the order of the Chilian Government for a cruiser building at Elswick. There would be no difficulty in mounting the smaller class of quick-firing guns on these machines, of course specially designed for the purpose; and on a small vessel, in which the motion is very quick and the difficulties of accurate shooting great, it ought to be very effective. For larger guns, an automatic firing apparatus has been designed for attachment to this machine, so as to fire the gun electrically at the right moment in the roll.

The discussion was opened by Mr. J. I. Thornycroft. He said that he had had an opportunity of seeing and testing Mr. Tower's platform for himself. He had stood on the platform during rough weather in the Solent, and experienced the sensation of looking down and watching the vessel rolling under him while he himself was in comparative equilibrium. Such rolling as he could feel was exceedingly small. He had also seen from a distance the effect of a search-light mounted on the platform. Although the night was rough, the vertical motion of the light was almost nil, and resembled, when revolving on a vertical axis, nothing so much as a lighthouse beam. With regard to the structure, Mr. Tower had attacked a difficult problem and had arrived at a simple solution. He had successfully overcome the unavoidable difficulty of external force applied to the upper part of the structure. This, of course, could have been overcome by a change of the pressure of the water admitted to the cylinders, but the port arrangement, he thought, was better. With regard to gun-fire, Mr. Tower had to give a popular illustration, reduced the flight of a snipe to that of a partridge as the target would be moving uniformly instead of in a zig-zag fashion—anyhow. The former is difficult enough, but the latter well nigh impossible.

Mr. Brunel said he had also sat on Mr. Tower's apparatus, early in 1889, before the correcting cylinders had been added. The boat was rolling at an angle of from 20 deg. to 30 deg. They had a mock gun. The utmost error observable on this occasion was about ½ deg., and this did not arise suddenly but gradually, at a rate of less than ¼ deg. at each roll. Afterwards the machine was tried again at the Needles, and found to be a thoroughly practical machine, in that it stood the test of being in the hands of people who had previously never had anything to do with it. The correcting cylinders had then been added, and they corrected every error.

Mr. Tower, in replying, said he had first started with a small model, and, with regard to sensitiveness, had arranged that a very small angle would cause sufficient change at the ports to enable them to operate, and this arrangement was too good, too sensitive; the action was so quick and violent that he had to allow of there being some error, this to be corrected by means of the correcting cylinders. In the torpedo boat Bloodhound, on which experiments had been carried out, the captain of H.M.S. Vernon had worked an apparatus, entirely by himself, which had not been in use for three or four months. There used once to be a slight quiver in the platform, but that had now been overcome. In an experiment which had been conducted recently by Sir W. G. Armstrong, Mitchell, and Co., on a boat which was caused to rock by a number of men running to and fro athwartships, a spot of light thrown on a neighbouring ship was found to remain absolutely stationary. A vote of thanks was passed to Mr. Tower, and the proceedings terminated.

HORSELESS CARRIAGE NOTES.

THE Exhibition of Horseless Carriages at the Imperial Institute will contain a large number of motor-propelled vehicles of very various designs, and by French, German, and English makers. They will also include motor omnibuses, vans, and motor cycles. A private view of the exhibition will take place this afternoon for the reception of members of the House of Lords, and the opening of the exhibition will take place on the 9th inst., when the Prince of Wales will perform the ceremony. The exhibition has been organised by the Motor Car Club, which is affiliated with the Automobile Club of Paris, and with other similar organisations, supported by all the at present best-known makers of steam, oil, and electrically-propelled vehicles, and the exhibition will represent all these different interests and makers. There will, of course, be a considerable number of vehicles, by several different firms, driven by benzoline motors of the Benz and Daimler types, the latter predominating, just as they did in the Paris and Bordeaux races. This is a result of the early appearance in the field and the suitability of the Daimler motor for the requirements of the several carriage-builders in Paris and Switzerland who adopted these motors, and it appears now probable that the legal difficulties in the way of the use of the light oils will soon be removed or lessened in this country. The electrical and steam motors, appear, however, to be gaining more and more favour, and the Count De Dion and M. Serpollet, and others, are probable exhibitors.

IN moving the second reading of the Locomotives on Highways Bill in the House of Lords last week, Lord Harris and Viscount Clifden made some remarks which are in support of the observations we made last week as to the haulage of one vehicle by another. Lord Harris said the use of light locomotives, capable of going at a fair pace on the highway, had become common in some countries on the Continent and in America, and it was not unnatural that those who wished to use such locomotives should claim to have a chance of turning their attention to an industry and means of conveyance which was obviously very useful; but they found that they were obstructed in this country by impediments which were not in existence on the Continent. Parliament had been extremely jealous about the safety of the public, and had imposed a considerable number of rules, and passed a very considerable number of laws, regarding the use of locomotives. It was ludicrous that the same provisions should apply to a vehicle of a hundredweight or so as were applied to a locomotive of several tons. He was informed that there were at present persons who were prepared to put on the streets of London, provided the power were given by Bill, electric omnibuses, which they maintained would be as convenient in every respect as the present means of locomotion. The method adopted in the Bill was, first, to exclude light locomotives from most of the provisions of the existing Acts which applied to ordinary locomotives, and then to lay down a certain number of restrictions which should specially apply to the lighter vehicles. It was provided that their weight should be limited to two tons, but he was informed that this maximum would render the use of light locomotives impossible, and Mr. Chaplin was ready to listen to any evidence placed before him as to what would be the proper weight to fix as a maximum. Another provision was that a light locomotive should not draw any other vehicle after it. He thought this was a wise provision, as there would be danger to other vehicles from these light carriages suddenly coming round a corner, no limit being fixed as to the speed at which they should run. It was also provided that no smoke or vapour should be visible in the running of these vehicles; but he had been told by a gentleman who had been using these carriages on the Continent that, in certain states of the temperature, it was impossible to prevent a certain amount of vapour escaping so as to be visible. Probably, it would be necessary to introduce in the Bill some words which would remove this disability. There was special provision made in the Bill to safeguard the keeping and use of petroleum and other inflammables in connection with these light locomotives. It was further provided that any person driving a light locomotive negligently should be liable to a heavy penalty, and the Local Government Board reserved to itself power to make regulations with respect to the use of light locomotives on highways, while in the first clause it was provided that nothing in the section should affect the existing general powers with respect to the regulation of traffic on the highways. There was an earnest desire in the country that a Bill of this kind should be passed, and the Local Government Board had, perforce, to draft the Bill rather in the dark, having no experience of light locomotives in this country; but they would, of course, be ready to give their consideration to any proposal for amending it which might be thought necessary. Viscount Clifden welcomed the Bill, but took some exception to the provision which prevented a light locomotive from drawing any other vehicle after it. The Earl of Morley pointed out that, as at present drawn, the Bill would exclude these vehicles from the liability to pay the toll which, under the Act of 1861, still existed on certain roads and bridges. Lord Harris promised that full consideration should be given to the points raised.

THERE is obviously some misconception in the reasons urged against a locomotive vehicle drawing another. There would be no additional risk of danger to other vehicles when locomotive vehicles suddenly turned a corner, for it is the leading vehicle which, like any ordinary vehicle, would be the cause of danger to other vehicles crossing the corner. The addition of a carriage behind the leader would make no difference. There are many reasons for permitting the use of a mechanically-hauled vehicle, whether behind a motor carriage or behind something more truly of the nature of a locomotive.

ANXIOUS as Australians may be to adopt motor carriages when available, their import duties will be much against them. In reply to a letter from Messrs. Phillips, Ormonde, and Co., of the 12th of December, respecting duty on "horseless carriages," Mr. H. N. P. Wollaston, Secretary of Customs, stated that "duty will be charged on the vehicles under the heading of carriages, carts, and conveyances, according to their designation. A further charge will be made for the motors as machinery, which will be dutiable at the rate of 25 per cent. on and after January 1st next." Although duty is high, it appears that regulations are easy, for in reply to a letter on this subject, Mr. John Clayton, Town Clerk of Melbourne, writes that he is not aware of any bye-law prohibiting the use of such vehicles in the streets of Melbourne. "They will, however, of course, be subject to all bye-laws and regulations regarding street traffic."

SOME OF THE DIFFICULTIES IN DESIGNING RAIL SECTIONS.

MR. DUDLEY, writing to the editor of the *Railroad Gazette*, says:—

"The area of but few sections for the given weight per yard seems to be correctly determined on the drawings for the standard measures and weight before the dimensions are sent to the mills; the figures will not be corrected there. A part of this discrepancy in the area is due, in laying out the section, to the use of scales originally inaccurate, or that have become so since they were divided, the stamp of 'U.S. Standard' on them being no longer a guarantee of their correctness. A fine 12in. U.S. Standard scale divided in 1894, and used daily in August and September of that year, is now 0·012 of an inch shorter than when I obtained it, most of the error being in the six inches principally handled and used. An expensive English ivory scale I have used is $\frac{1}{32}$ of an inch short in 12in., and is only used when I wish to compute an English section from the dimensions given per yard. An English section laid out with our U.S. Standard I have always found to exceed the weight given per yard. My 80 lb. section, rolled in England, is lower than our standard measures, the weight being made up by a slight increase in thickness of web and head.

"At the mills the dimensions for the section go to the roll designer, who determines and lays out the passes for the rolls on paper, estimating the allowance to be made for draft, flow, speed, and shrinkage of the hot metal. Then the hot templates are made, from which to turn the rolls.

"The rolls are driven according to their pitch diameter, and those portions of the pass which are sunk deep into the body of the rolls, the bottom of the pass being so much less than the pitch diameter, describe a less distance; therefore the metal in some portions of the pass must slip. This becomes a very serious matter for the manufacturer with sections having wide flanges, as the extreme width must slip through the bottom of the pass faster than the bottom of the rollers is moving, and a great many seconds will be made unless the angle for the base is large, for good delivery. Outside of the mills little is known of the difficulties and intricacies of roll designing and turning and rolling the steel.

"The shrinkage of the steel in the different types of sections cannot be the same, nor is it the same in all portions of the section. The more massive portions of the section have more heat units to be dissipated than the thinner portions, recalescence occurs at different times and the shrinkage is unequal. Of course allowance is made for this, but it only can be a mere approximation. In the light and low sections it was not so important or difficult as it is in the heavier and higher sections now in use. A bar finishing 100 deg. lower than the usual run will not shrink as much and will be higher. For the same reason there is often a slight difference in height between the rail from the top of the ingot and the one from the bottom. When the rolls are first turned they are intended to be low, and as they wear and are dressed, the height increases. Most specifications allow a variation of $\frac{1}{32}$in. under and $\frac{1}{32}$in. over the standard height. This is too much for the standard of track now desired for the present speed and heavy rolling stock.

"When one looks at the rolls for a section and all the provisions which must be made for its rolling, one can readily see it is only by the great skill acquired by long experience, that as good work is produced as is generally turned out by the present system of rolling, being obliged to shape and form the section so largely by longitudinal flow of the metal."

DEAD WEIGHT POWER.

THERE are still persons extant who think that power can be got from weights, springs, and similar devices, and one of them recently wrote to the *American Machinist*, asking details of a machine for driving by weights. The reply is so well given and patiently worked out that we quote it for the benefit of persons who want similar information.

"A horse-power being 33,000 foot-pounds per minute, the total required for one horse-power for five hours would be 33,000 × 60 × 5 = 9,900,000 foot-pounds; and as this is the power to be realised, we must add, say, 10 per cent. to this for the friction of the apparatus; 9,900,000 + 990,000 = 10,890,000 foot-pounds, or, as more convenient, we will say 11,000,000 foot-pounds. If the weight is to be wound up to a height of 10ft., and to descend that distance when doing its driving, then, of course, only one-tenth of this weight will be required, or 1,000,000 lb., or 550 tons.

"For a weight for this purpose, there might be some discussion both as to shape and material. Our idea is that a spherical cast iron weight would be the neatest thing to use. It is like an obelisk for a cemetery; it requires no discussion except about the dimensions and cost. Now, as we must have 1,100,000 lb. of cast iron, and as one cubic inch of cast iron weighs, say, ·27 of a pound, our ball must contain 1,100,000 ÷ ·27 = 4,074,074 cubic inches. Then the diameter of the ball will be the cube root (4,074,074 × 0·5236) = 198in., or 16ft. 6in. This ball could be cast at any foundry where they do such work, and at two cents per pound it would cost 22,000 dols. We cannot say anything about the freight on the ball, as we do not know anything about how far it would require to be transported, and the railroad is not yet built that could carry it.

"Some persons might think that we might have allowed more vertical travel for the ball, and so have made it lighter; but we think not. Supposing the weight to stand on the ground, we would have, first the diameter of the ball 16ft. 6in., then about 2ft. of waste height for attaching the chain, 10ft. for the distance to rise and fall, and say, 5ft. to clear the circle of the drum, making 33ft. 6in. from the ground to the centre of the drum shaft.

"We could use a common link chain for suspending the weight, and it might be made by any blacksmith who would undertake the job. Twenty feet in length would probably be enough, and if we assume the iron to have a tensile strength of 40,000 lb. per square inch, this would call for 1,100,000 ÷ 40,000 = 27·5 square inches, which is about the area of a 6in. circle; so that we ought to use not less than 6in. round iron, the two sides to the link only giving a little factor of safety. The piece of chain would weigh about three tons, and, as blacksmithing goes, it probably could not be got for less than 5 c. per pound, which would be 300 dols. This is for the bare chain, and has nothing to do with the fastening of it either to the weight or to the drum, which would add considerable to the cost.

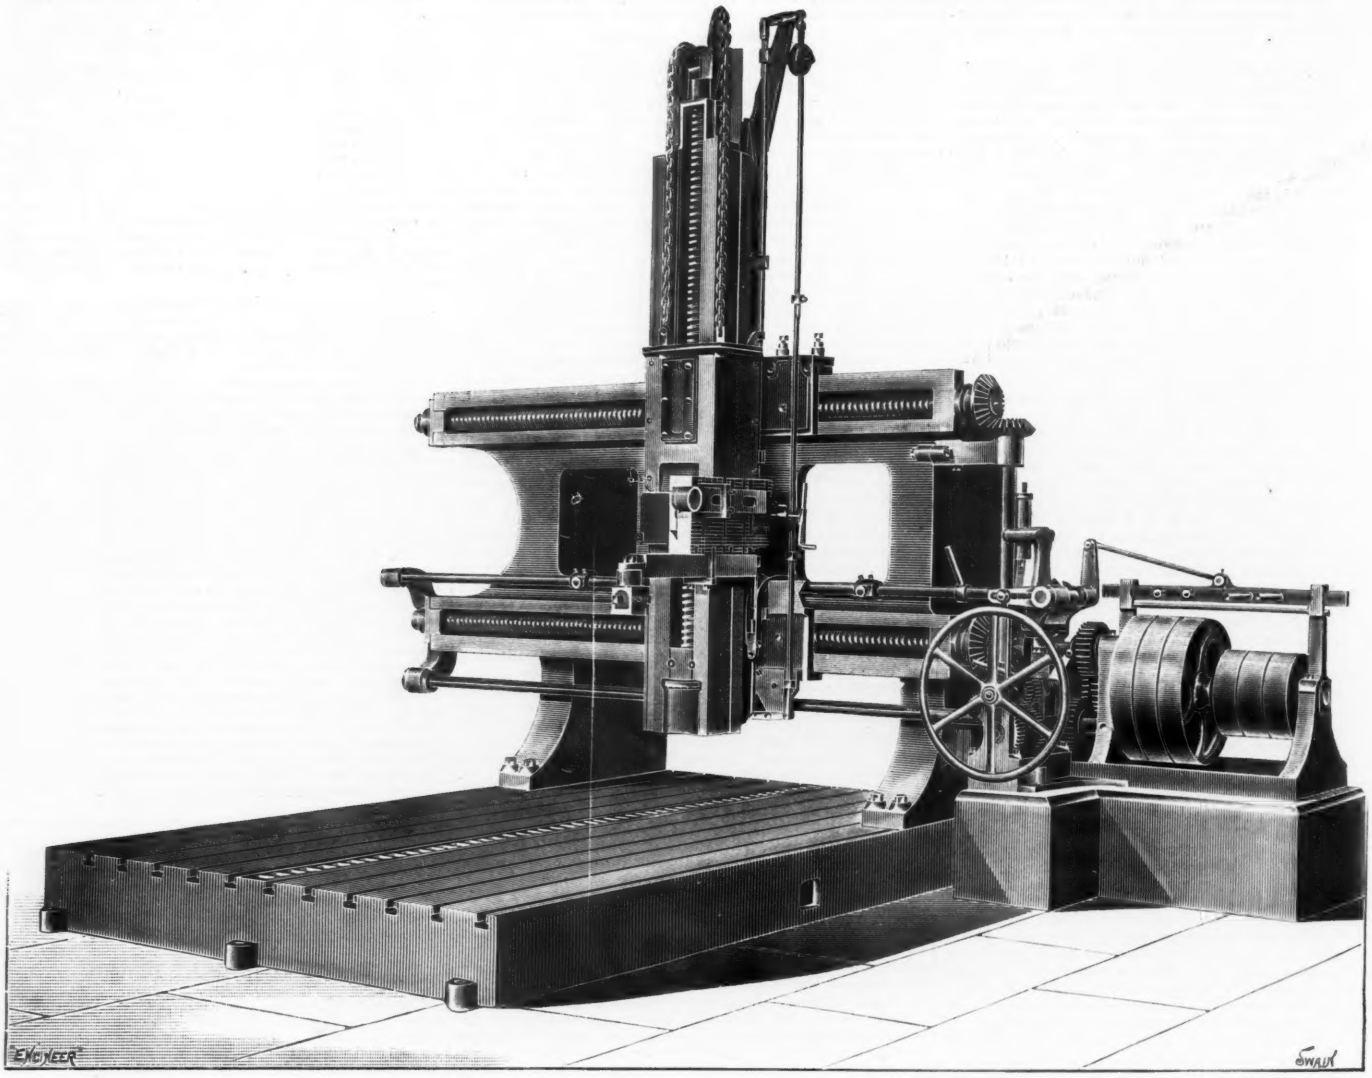
"We spoke of a drum, but there would, in fact, be no drum, but only a simple wheel of sufficient diameter to allow the necessary travel with a little less than one revolution, the end of the chain being fastened securely to the periphery. If the wheel were 4ft. in diameter it would be big enough.

"We would have, then, this wheel in the middle of a shaft, and two standards, say 17ft. apart, so that the weight would swing between them. The standards would, of course, be the bearings for the shaft, and the first driving gear would be on the end of the shaft, outside of one of the standards. The shaft journals should be about 30in. in diameter and 40in. long, the shaft, of course, being larger in the middle.

"Having brought the matter thus far along, we felt it our duty to leave it, as it is not proper for us to take the work from the competent mechanical engineer, who should be employed to complete the design and superintend the construction. Before going further with the case, it might be well to remember that three quarts of oil in an oil engine would furnish as much power as could be got from one descent of the weight which we have been figuring on. Possibly the oil arrangement might be the simpler and cheaper one."

HORIZONTAL AND VERTICAL PLANING MACHINE

MESSRS. THOMAS SHANKS AND CO., JOHNSTONE, N.B., ENGINEERS



HORIZONTAL AND VERTICAL PLANING MACHINE.

THE illustration above, from a photograph, shows a small horizontal and vertical planer of moderate dimensions, which has been designed and made for Messrs. W. H. Allen, Son, and Co., Bedford, to plane vertically 6ft., and horizontally 8ft. Although there is a clear space for work to pass under the slides, the tool is made to come down close to the base-plate, and this space is also utilised for a revolving table—not shown—to pass below, for obvious purposes.

By the use of a disengaging detail a quick return of 3 to 1 is secured. There are also other details for doing work quickly, which the illustration clearly shows, and which are the result of much experience in larger machines. The tool slide is prepared for Barrow's patent duplex tools. A similar machine to this is being made for the new firm of Messrs. McKie and Baxter, who are starting in Glasgow the manufacture of small marine engines, and another is in hand for a Greenock firm.

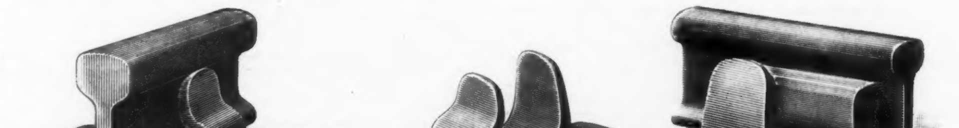
TRACTION ENGINES ON ROADS.

THE witnesses examined by the House of Commons Committee on Thursday, the 23rd ult., were Sir Charles Lennard, the chairman of the Kent County Council, Mr. Ruck, surveyor to the county of Kent, and Mr. W. B. Prosser, clerk to the same County Council. The first-named witness spoke of certain damage done in Kent to house property by vibrations set up by passing traction engines, and said he would not like to see the maximum limits of speed increased. He thought it desirable for the safety of the public that the drivers of road locomotives should be certificated. Mr. Ruck, in the course of his evidence, gave some interesting figures relating to the maintenance of roads in Kent, showing that when once the roads had been brought up to traction engine standard by strengthening the foundations, the expenditure in their upkeep was no larger, but rather less than when made to the lower standard necessary for ordinary traffic. The "extraordinary traffic" clause was the chief subject upon which Mr. Prosser was examined. He suggested to the Committee that cases of litigation under this clause should be heard by the county courts instead of by the justices, as at present, and that this clause ought to be amended to read "for whose benefit the traffic is conducted," instead of "to whose order the traffic is conducted."

On Monday last the first witness to give evidence was Mr. Wilmot, county surveyor to the Warwick County Council. This county has 465 miles of rural district roads, maintained at an annual expenditure of £60 per mile, and the bye-laws of the Council prohibit engines from travelling during "the early hours of the night." In granting licences in this county the licensee is required to undertake to make good all damage done to roads by his engines. Although it is open to question whether the above body has the power to make a condition of this kind, the witness considered that it had been the means of preventing damage to the roads by heavy locomotive traffic. It may be pointed out that in Warwickshire the net load carried by any one truck is restricted to 12 tons, but as much as 20 tons is sanctioned in the case of boiler haulage. Mr. Wilmot does not see any objection to the maximum limits of speed being increased to six and three miles instead of four and two miles as now.

Mr. Platt, A.M. Inst. C.E., Borough Surveyor of Rochdale, complained chiefly of the damage done to the roads in his district by the legalised wheels with cross-bars, and advocated the abolition of this restriction, so as to allow any approved form of wheel to be used. He would not consent to the power for making bye-laws being taken from local authorities and placed in the hands of a central authority, even though such a body were prepared to receive suggestions from the districts interested. Mr. Gadsby, Surveyor to the county borough of Derby, informed the Committee that their bye-laws prohibited the use of traction engines between the hours of 5 p.m. and 12 p.m., and in addition, between 9 a.m. and 5 p.m. upon certain busy streets. The licence fee per engine in Derby is £10, with a rebate of £5 in cases where engines have previously been licensed in neighbouring counties. He would resist the handing over of the power to make bye-laws to a central authority.

After hearing the evidence of Mr. Crear, City Surveyor of York, who appeared generally satisfied with the working of the laws governing the use of traction engines on roads, the Committee again adjourned until yesterday—Thursday—the proceedings of which will be reported in our next week's issue.



MUIRHEAD'S WROUGHT STEEL CHAIR

MUIRHEAD'S WROUGHT STEEL RAILWAY CHAIR.

THE engraving above illustrates a forged steel railway chair, which is remarkable in its process of manufacture, and in the fact that the advantages of forged steel are secured at the price, it is claimed, of cast iron chairs. A rolled billet is by a special process split up from either end, the piece sheared, forged, and bent up at either end, one to form the straight, and the other the bent horn. The central part between the horns is forged to shape, the holes punched, and the chair is completed and has only about three-sevenths to half of the weight of the cast chair. They are not only stronger, but have the same or greater bearing surface than the cast iron chairs they replace, and, being identical in type, they take the same key and spike, and are thus interchangeable. Under very severe tests they have proved of remarkable strength, and, in fact, no tests were sufficient to break the chair even in the gullet, where ordinary chairs so readily give way. They are made in Glasgow under Muirhead's patents, and are shown in London by the agents, Messrs. John H. Austin and Co., 61, Gracechurch-street. Several miles have been in use for some time now on our leading railways.

LONDON ASSOCIATION OF FOREMEN ENGINEERS AND DRAUGHTSMEN.—The forty-third anniversary festival of this Association was held on Saturday last at the Cannon-street Hotel, and was largely attended. Mr. John Wolfe Barry, C.B., F.R.S., Vice-President Inst. C.E., presided, and amongst the other gentlemen present were Mr. H. M. Stanley, M.P., Vice-Admiral the Hon. Sir E. R. Fremantle, the Hon. and Very Rev. Dean Fremantle, M.A., Mr. A. R. Binnie, M. Inst. C.E., Mr. A. T. Simpson, M. Inst. C.E., Mr. Jeremiah Head, M. Inst. C.E., Mr. E. W. Moir, M. Inst. C.E., and Mr. William Royal, the president. This society was formed in 1852 by a few foremen engineers, with the object of fostering congenial fellowship. With the gradual displacement of "rule of thumb" by scientific knowledge, however, the usefulness of the society was increased by the reading and discussion of papers on mechanical and other scientific subjects. Moreover, the Association is largely a philanthropic one, and has considerable funds accumulated for the assistance of unemployed members, the partial maintenance of members suffering from permanent infirmities, and widows and orphans. Considering the advantages to be derived from such an institution, therefore, it is not surprising that the London Association can lay claim to a membership exceeding 250. The festival on Saturday comprised a dinner and an excellent musical programme, and was much enjoyed, but the toast list was a very heavy one, and might with advantage have been curtailed. The remarks of one of the proposers of toasts, too, were not of a kind calculated either to further the original good object of the society or to bring credit upon such a time-honoured institution.

RAILWAY MATTERS.

At the beginning of this year, 58 per cent of the Russian freight cars had had their capacity increased to 27,000 lb. Until recently, according to the *Railroad Gazette*, the standard was about 22,000.

The London, Chatham, and Dover Railway Company announces that it has arranged with the Hungarian State Railways for the issue of through return tickets from London to Budapest, at reduced fares, for visitors to the Exhibition at Budapest. The return tickets will be issued by express train services *viâ* Dover and Calais, Dover and Ostend, and Queenboro' and Flushing. The same Company also announce special arrangements for the conveyance of passengers to Berlin, for the Industrial Exhibition about to be opened there.

Recent reports state that the number of miles of new line opened in Russia in 1895—excluding the Siberian Railway—is 550 miles, and the total Russian mileage at the end of the year—excluding Asiatic Russia and Finland—was 21,366 miles, of which 4924 miles is double-track railroad. More than 2000 miles were taken into the State system in 1895, which has now 63½ per cent. of the whole. A great deal of railroad work was done last year on lines not yet open, and these and the lines whose construction was resolved upon that year amount to about 8230 miles—including the Siberian line.

A Brussels newspaper says that the Government has determined to unite the two great terminal stations in that city by six underground tracks, and to construct a central station and a girdle line around the city. Two of the underground lines are to to be worked by electricity, and the fare from all points on the girdle line and the underground roads to the Central on any other station is to be at the uniform rate of two cents. The cost is estimated at £2,800,000, and the capacity at 300,000 passengers daily. The actual traffic is estimated at 40,000,000 passengers yearly, the gross earnings at £160,000.

The gauges adopted by the Colonies of Australia can be seen at a glance by the following figures:—New South Wales, 4ft. 8½in.; Queensland, 3ft. 6in.; South Australia, 5ft. 3in. and 3ft. 6in.; Victoria, 5ft. 3in.; Western Australia, 3ft. 6in. The lines have been constructed generally by private firms, under the supervision of the Government engineers. In New South Wales and Victoria the lines are fenced throughout, but in the other Colonies they are only partially fenced. The "Pioneer Lines," Narrabri to Moree, 63 miles; Parkes to Condobolin, 60½ miles; and Jerilderie to Berrigan, 23 miles, which are now under construction in New South Wales, will not be fenced.

The following figures show the estimated populations in June, 1895, of the various Colonies of Australia, the miles of railway open, and the population per mile:—New South Wales: Population, December 31st, 1894, 1,250,450; miles of railway, 2615, inclusive of 84 miles of private railways; and the population per mile, 479. Queensland: Population, December 31st, 1894, 445,155; miles of railway, 2379; and the population per mile, 187. South Australia: Population, December 31st, 1894, 352,402; miles of railway, 1738½, inclusive of Palmerston line, 145½ miles (N.T), and 16½ miles private lines; and the population per mile, 203. Victoria: Population, December 31st, 1894, 1,179,109; miles of railway, 3120; and the population per mile, 378. Western Australia: Population, December 31st, 1894, 82,072; miles of railway, 1145, inclusive 572 miles of private railways; and the population per mile, 73.

A law compelling railways to carry bicycles in baggage cars free was passed by the New York Legislature on April 8th. Section 37 of the railway law, fixing the maximum limits for the rates of fare on the railways of the State, says that the rates named are for "a passenger and his baggage," and sec. 44, c. 565, prescribing the regulations for checking baggage when taken for transportation, now has the following paragraph added to it:—"Bicycles are hereby declared to be and shall be deemed baggage for the purpose of this article, and shall be transported as baggage for passengers by railway corporations, and subject to the same liabilities; and no such passenger shall be required to crate, cover, or otherwise protect any such bicycle; provided, however, that a railway corporation shall not be required to transport, under the provisions of this Act, more than one bicycle for a single person." The Bill was passed in the Assembly by a vote of 127 to 1.

The cost of construction per mile of line in Japan, according to the report for the year ending March, 1894, varied considerably according to the circumstances under which it was carried out. That of the Tokyo-Yokohama section of 18 miles was 162,741 yen per mile; but this being the first railway undertaken in the country was necessarily expensive, as it was superintended by foreign engineers and carried out to a considerable extent by foreign labour. The same was true, although to a less degree, of the Koke Otsa section, which was begun in November, 1870, and completed in September, 1879, and of which the cost per mile was 142,659 yen—or dollar. Probably the Yokohama Oguki section, which was began August, 1885, and completed April, 1889, may be taken as representing the best average conditions. Its length is 258 miles, and its average cost per mile was 52,156 yen. As indicating the great reduction in the cost of construction, the report shows that before the nineteenth fiscal year the amount of fixed capital per mile of line open in the Government railways was 104,697 yen, whereas in the twenty-sixth year it was only 64,671 yen. The decrease arose not only from the cheaper method of construction adopted, but also from the fact that the services of foreigners were almost entirely dispensed with, and native material and manufacturers employed as much as possible. The proportion of working expenses to the revenue is 36 per cent., and when compared with that of the previous year shows a decrease of 11 per cent., obtained from a large increase in the earnings, and decrease in the expenses incurred in operation, especially in the locomotive expenses, and the low price of coal which prevailed during the year.

The interior of Australia is without important river courses, the rivers that do exist are too shallow and uncertain to allow of perfect dependence being placed on them at all times, and the railways must come in to give a continuous and trustworthy means of communication between inland plains and the sea coast. This explains the continual demand for new lines of railway as the only means of internal development; and though it would be distinctly unwise to attempt to diminish any of the safeguards that have been adopted for the prevention of expenditure upon commercially hopeless lines, a too close scrutiny of the immediate ability of new routes to be made remunerative—bearing in mind that the railways are not only the main arteries of industrial communication, but the real pioneers of settlement, developing the immense resources of inland Australia wherever they trend—should not be allowed to weigh too heavily against their construction. A reliable, ready, and not too expensive means of communication with the seaboard is as necessary to the settler and producer as even the land itself. It can be seen by a reference to maps that the needs of the population in respect of railway accommodation have been, on the whole, as well met as a policy of encouragement to the development of the natural resources of the country, coupled with a due regard to economical considerations, will allow. By way of showing comparatively the progress made by the railways—Government and private—in the whole of Australasia, it may be remarked that here there are 31·5 miles of line for every 10,000 inhabitants, as against 3·9 miles in Europe, 26·7 miles in the United States, and 31 miles in Canada. The number of miles open for each 100 square miles of territory are:—Australasia, 0·40; Europe, 3·8; United States, 5·9; Canada, 0·5.

NOTES AND MEMORANDA.

In a paper in the *Comptes Rendus* on "Fallow Ground," by M. P. P. Dehérain, the ancient practice of allowing land to lie a year fallow after three years' cultivation is shown to have rested upon a sound basis, the land increasing considerably in nitric nitrogen during the fallow year. With modern manures the necessity for this no longer exists, although the practice still survives in many parts of Europe.

At a recent meeting of the Berlin Physical Society, Dr. Lindau, of Munich, spoke on the cooling of gases during their adiabatic expansion, and showed that from this the specific heat of the gases may be determined. In opposition to this view Professor Planck pointed out that the cooling does not depend solely on specific heat, but also on the extent to which the gas differs from the condition of a perfect gas.

According to a recent paper in the *Comptus Rendus* on the products of combustion of an acetylene burner, and explosive mixtures of acetylene and air, by M. N. Gréhant, the combustion of acetylene in an ordinary fish-tail burner is complete, the products not comprising the least trace of a combustible gas containing carbon. With mixtures of acetylene and air the most violent explosion was produced when the volume of air was nine times that of the acetylene.

The tendency in America, where boilers are so much used of the water-tube type, is to use water separators of large size, which serve as reserves of steam close to the engine. The *Electrical Review* says, the United Electric Light and Power Company, of New York City, have recently applied four Stratton separators to their 1200-horse power of Westinghouse engines, and report that the pressure variation as between the engine and boilers scarcely varies, and the pulsation in the steam pipes is practically stopped, as proved by the practical abolition of all vibration.

The annual report to the City Corporation by Mr. A. J. Street, the chief inspector of weights and measures, shows that last year the inspectors visited 5371 places of business and examined 24,646 weights, 29,436 measures, and 6689 weighing instruments, as against 4074 places of business, 25,635 weights, 37,591 measures, and 5754 weighing instruments in 1894. The seizures last year were 23 weights, two measures, and three instruments, while some others in each category required adjustment or stamping. Of 30 cases reported to the City Solicitor, 19 persons were proceeded against, of whom 16 were convicted. The indoor work of the department included the verification of 293,785 weights, measures, and instruments, of which 257,308 were certified and stamped and 36,477 rejected. The fees for stamping amounted to £1312.

It has occurred to many people that perhaps celluloid might be useful as an insulator for electric cables, and in a letter to *Nature* on buried celluloid Professor George Forbes says:—"I feared it might deteriorate. I have made an experiment of 4½ years' duration which may be of use in connection with the subject. On August 15th, 1891, I took four photographic quarter-plate celluloid plates, with the gelatine removed, and treated them as follows: No. 1 was nailed to an outhouse, and became rotten in a year; No. 2 was 1ft. deep in garden soil; No. 3, 1ft. deep in gravel; No. 4, 1ft. deep in a rubbish heap. The last three were dug up on April 6th, 1896. Nos. 2 and 4 were in as perfect a condition as ever. No. 3 has some sand rubbed in, but is perfectly sound. The experiment was made at Pitlochry, N.B. The specimens can be seen at my office."

The rock salt mine at Friedrichshall, Würtemberg, which has been actively worked for the last thirty-five years, and where an inburst of water lately occurred, would soon have required a new shaft for ventilation and ensuring safety to the hands. The water burst in at the roof of the oldest part of the mine, to the north of the shaft, adjoining a rock wall for protecting that portion; and there is little doubt—observed Dr. Von Baur to the Verein Deutscher Ingénieure—that some of the older pillars that had become weakened in course of time gave way, which caused the falling in of the roof. Thereupon the water from the strata above, which had given great trouble while the shaft was being sunk, poured into the mine at the rate of 1000 cubic metres—220,096 gallons per hour. The accident happened on a Sunday at ten minutes past six in the morning, when there was no one in the mine, but the neighbouring inhabitants were startled by a heavy shock like that of an earthquake that was felt in Mannheim, Wimpffen, and a whole series of more distant localities, while on the surface the shock caused a perceptible subsidence of hopper form. Though it would be possible to clear the mine, this course is not considered advisable, because the fresh water that burst in will have dissolved so much salt, that its pumping out might cause a still more extensive subsidence.

Some results of recent investigations on earthquake pulsations are described by Prof. G. Vicentini. The instrument employed is the microseismograph designed by himself (*Nature*, vol. li.) and now erected in the Universities of Siena and Padua. The motion of the paper on which the pulsations are recorded is unusually rapid, and this has allowed a detailed examination of their nature to be made. Prof. Vicentini distinguishes, as a rule, three phases in each disturbance. The first consists of rapid vibrations and small oscillations; the second of large, and more or less irregular oscillations, with several maxima which begin and end abruptly; in the third phase the pulsations become more regular, and are longer in period. Throughout nearly the whole movement, but especially during the last two phases, the mean position of the pendulum generally undergoes a continuous change, showing that with the more rapid oscillations there coexist long, slow waves with a period of at least twenty seconds, which result in a gentle tilting of the surface of the ground. If the earthquake is a severe one, and the origin at a great distance from the place of observation, the three phases are separated from one another. But, as the distance of the epicentre diminishes, the first two phases partly coalesce, and the rapid vibrations are superposed on the earlier long-period oscillations. When the earthquakes are weak and of local origin, the tilting of the ground is still observed.

The measures proposed by the Italian Government for the relief of the sulphur industry of Sicily lend interest to a report by the United States Consul at Catania on the present condition of the Sicilian sulphur mines and miners. The industry is now in a deplorable state owing to over-production and low prices. The Consul does not see how the production can be reduced; for the mines must be worked, if only to keep out the water, which accumulates rapidly and would soon ruin them. The proposition which appears to have found favour with the Government has been the establishment at the ports of warehouses, where certificates should be issued for the sulphur deposited, which certificates might be discounted by the banks. In addition, a reduction of export duty, which amounts to about 8s. 6d. per ton, is asked. The price of sulphur has fluctuated considerably, that for "best thirds unmixed" having been as follows in the respective years per ton:—1876, 120 lire; 1879, 97·41; 1884, 89; 1886, 76·20; 1891, 115·59; 1895, 55 lire. The wages of the miners have necessarily gone down with the prices, so that now they have fallen to 3½d., 4d., and at most 5d. per day. For many years the quantities mined have largely exceeded those exported, and in 1894 and 1895 the excess was over 300,000 tons. The report of great sulphur deposits having been found in Louisiana, and of plants for working them, has naturally added to the depression in Sicily. So backward is the industry in other respects that the fusing of the sulphur in the primitive furnaces can only be done at certain times of the year, after harvesting the crops, which would be ruined by the fumes. The modern works at Catania can, of course, remain in operation all the year round.

MISCELLANEA.

The Bath and West and Southern Counties Society's St. Albans show at St. Albans, will commence on Wednesday, May 27.

Messrs. Thornycroft and Co. have received orders from the Admiralty for three 30-knot and one 32-knot torpedo catchers.

Large petroleum deposits have been discovered near Conil in the province of Cadiz. The territory was recently inspected by the chief engineer of the province, and English engineers were engaged to commence drilling.

A further series of trials is to be made with the automatic boiler feed, recently fitted to the torpedo-boat destroyer Lynx, at Devonport. The *Naval and Military Record* says that the new gear fitted in this vessel has not so far proved satisfactory.

An interesting article on "English Coins," by Mr. G. F. Hill, M.A., the first of a series, appears in the May number of *Knowledge*, accompanied by photographic reproductions of about forty coins, dating from 180 B.C. Other articles fill a very interesting number.

The model of the twin-screw armoured barbette battleship Fuji, built by the Thames Ironworks and Shipbuilding Company, the latest addition to the Imperial Japanese Navy, has been lent for a short time to the museum of the Royal United Service Institution, Whitehall.

The Blackwall tunnelling operations have now reached the No. 1 shaft, and in the course of a few weeks the shield will be got on to the last lap. On Whitsun Monday the public will be admitted to the tunnel at a small charge, and the receipts are to be handed over to some of the hospitals.

Stability in warship construction is apparently now receiving more consideration from the French naval authorities than it has in the past, as we read that the trials of the cruiser Descartes at Brest have been postponed, on the ground that the hull does not attain the requisite conditions of stability, therefore cannot yet be accepted.

A new blast furnace on the American system, designed for a daily out-turn of 200 tons, has been blown in at the Cockerill Works, Seraing, in the presence of M. Nyssens, the Belgian Minister of Works. This brings up to six the number of furnaces owned by the Cockerill Company, the blast for each of which is supplied by a separate blowing engine, while the pumps for all the furnaces require a force of 25,000-horse power, steam being raised in twenty-six water-tube boilers, fired by the furnace gases.

The output of pig iron in the German Empire—including Luxemburg—during March was as follows:—Puddling pigs and spiegel iron, 159,002 tons; Bessemer pigs, 46,013 tons; Thomas pigs, 281,465 tons; foundry pigs, 64,677 tons; total, 551,157 tons. The total in February, 1896, was 496,170 tons, and the total in March, 1895, 481,144 tons. The total during the quarter ended March 31st was 1,560,355 tons, against 1,405,423 tons, representing an increase as compared with last year of 70,013 tons, or 14·55 per cent. on the month, and of 154,932 tons or 11·02 per cent. on the quarter.

The Russian Government have just accepted a group of armour plates from the Carnegie Company, after a very satisfactory trial at the Indian Head Proving Ground. According to the *Army and Navy Gazette*, the armour was manufactured under a contract for 1100 tons made some months ago. Of the total bulk 350 tons are of 5in. thickness, 350 tons of 10in. and 400 tons of 14in. The trial plate, which was attached to a 36in. oak backing, was manufactured under the double forging process. Squares of twelve square feet were marked off on it, and six shots, five of 4in. diameter, weighing 33 lb. each, and one of 5in., weighing 600 lb., were delivered, each in one of these squares. The first shot struck the plate with a velocity of 1740ft. per second, the second with 1660ft., the third with 1690ft., and the fourth with 1760ft. All of the shells smashed on the face of the plate, after making a penetration of only a couple of inches. The fourth shot produced a crack in one corner, which was widened by the fifth shot, delivered at a velocity of 1760ft. per second. The sixth shot, of 5in. diameter, fired with a velocity of 1705ft. per second, although delivered some distance from the crack, produced a vibration which caused a fragment to break off.

The annual accounts of the Ordnance Factories for the year 1894-95, with the report of the Comptroller and Auditor-General thereon, have just been issued as a Blue Book. The accounts include those of the Ordnance Factories, the Royal Carriage Department, Royal Arsenal; the Royal Gun Factory, Royal Arsenal; the Royal Laboratory, Royal Arsenal; the Royal Gunpowder Factory, Waltham Abbey; the Royal Small Arms Factory, Enfield Lock; the Royal Small Arms Factory, Birmingham, &c. The total cost of work performed was £2,231,421 10s. 5½d. Of this amount £937,423 6s. 11½d. was for the army, £1,153,840 1s. 4d. for the Navy, and £140,158 2s. 2d. for India. The cost of guns manufactured in the Royal Gun Factory is set out in detail. One 13·5in., Mark III. F. (without sights) cost £10,255 18s. 7d.; two 12in. "wire" (without sights) cost £14,348 19s. 2d. each; three 6in., Mark VI., cost £999 18s. 9d.; one 6in. jointed cost £1637 4s. 2d.; one 30-pounder, 20 cwt., Mark I., cost £460 14s.; one 8in. howitzer (experimental) cost £1365 5s. 7d.; one 6in. howitzer (experimental) cost £761 16s. 9d.; one 5·4in. howitzer (experimental) cost £687 5s. 4d. The foregoing are B.L., complete with sights and fittings, except where otherwise stated. Under heading, "Ordnance, Q.F., complete," appear, among others, thirty-nine 6in., Mark II. (without sights), costing £1431 16s. 6d. each; sixty-two 4·7in., Mark IV. (without sights), costing £656 6s. 9d.; and one 4in. 25-pounder "wire," costing £1417 6s. 9d.

The Babcock and Wilcox Company have recently received an order for six of their marine type of water-tube boilers from owners who have already had experience of the boiler in actual working on board their ships over a considerable period. Boilers of the Babcock type have now been in use on board ship for over six years, and there are indications that their adoption on board merchant ships will soon be largely extended. The company's present business premises, forming a portion of the great pile of buildings of the Singer Manufacturing Company at Kilbowie, near Clydebank, having proved too small for its operations in turning out boilers for land and marine purposes with the despatch required, the Babcock Company is about to transfer its works to greatly enlarged premises on the other side of the Clyde, at Porterfield, near Renfrew. These are on the site of, and to some extent the same premises erected several years ago for the purpose of steel manufacture by the Renfrewshire Steel Company, but never properly set agoing in that capacity. The Babcock Company having some time ago purchased them, have since been busily adding to and re-arranging the works for the purposes of boiler manufacture. Entirely new plant has been laid down, and the company hope to have operations fully set agoing in the new works by the end of the present summer. One branch of the manufacture, which has hitherto been done by sub-contract, will now be overtaken at the enlarged works, viz., the manufacture of the drums, which form so important a feature in the make-up of water-tube boilers. For a number of years the company have had to requisition the services of some four or five firms in Glasgow and neighbourhood to undertake this work. The vertical connecting boxes or "headers," and other items in the building up of complete boilers, will be manufactured by new forging machinery of great interest, as also the machining and preparation of these items for taking their several places in the boiler. The tubing, which so largely enters into the construction of boilers of this type, will, of course, still be supplied by outside firms, the quantity of such material absorbed by the company being little short of a million lineal feet per annum.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

ALPHA (West Hartlepool.).—*You can obtain a list of several from Messrs. Spon, 125, Strand, or Phillips, 32, Fleet-street, London.*

IGNORAMUS.—*It may be taken for granted that under all circumstances a strict mathematical investigation will give more accurate results than a graphic investigation. But the mathematician must understand his business.*

J. C. M.—*On inquiry we find that there was a clerical error in the manuscript. The sentence on page 272 should read: "The present capacity of output is about equal to 50 tons of 60 per cent. white caustic soda, and about 100 tons of 35 per cent. bleaching powder from 60 tons of common salt weekly." At the time of our representative's visit the dynamos were working at about 700 ampères, but this is not necessarily a permanent current. They are sometimes run up 920 ampères or a little over.*

ONE WHO INTENDS TO COMPETE.—*If you will read the regulations with care you will find that they answer all your questions. The minimum run will be 100 miles out and 100 miles home. But there is no reason why it should not be twice as long if the judges should so decide. The competitors may go as they please, running at night or stopping at night as they think fit, so long as they complete the distance in the time to be fixed in the manner provided by the conditions. Every competitor must take care of himself; one of the objects of the competition is to ascertain how a horseless carriage will get on in a strange district.*

BALL BEARINGS FOR CENTRIFUGAL MACHINERY.

(*To the Editor of The Engineer.*)

SIR,—Could a centrifugal machine, weighing when loaded about 7 cwt., revolving from 1000 to 1200 revolutions per minute on a vertical shaft, be made to run on ball bearings—say three sets—if so, what would be a practical diameter for same? J. S.

Leicester, April 29th.

SUBSCRIPTIONS.

THE ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number) .. .. £0 14s. 6d.
Yearly (including two double numbers) .. .. £1 9s. 0d.

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—
Half-yearly .. .. £0 18s. 0d.
Yearly .. .. £1 16s. 0d.
THICK PAPER COPIES—
Half-yearly .. .. £1 0s. 3d.
Yearly .. .. £2 0s. 6d.

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF JUNIOR ENGINEERS.—Friday, May 8th, at 8 p.m. Paper: "Notes on Belgian Electrical Engineering Practice," by Mr. A. Anstruther-Thomson and Mr. G. C. Allingham, members.

INSTITUTION OF CIVIL ENGINEERS.—Tuesday, May 5th, at 8 p.m. Papers to be discussed: "American and English Methods of Manufacturing Steel Plates," by Mr. Jeremiah Head, M. Inst. C.E. "Four American Rolling Mills," by Mr. Samuel T. Wellman. Thursday, May 7th, at 8 p.m. "James Forrest" Lecture: "Physical Experiment in Relation to Engineering," by Dr. Alexr. B. W. Kennedy, F.R.S., M. Inst. C.E.

SOCIETY OF ARTS.—Monday, May 4th, at 8 p.m. Cantor Lectures: "Applied Electro Chemistry," by James Swinburne. Tuesday, May 5th, at 8 p.m. Paper: "Australia's Prospects in British Markets," by James F. Dowling. Sir Saul Samuel, K.C.M.G., Vice-president of the Society, will preside. Wednesday, May 6th, at 8 p.m. Paper: "High Explosives and Smokeless Powders," by Hudson Maxim.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, May 5th, at 3 p.m. Lectures: "Ripples in Air and on Water," by C. V. Boys, F.R.S. A.R.S.M., M.R.I. Thursday, May 7th: "The Art of Working Metals in Japan," by W. Gowland, F.C.S., F.S.A. Friday, May 8th, at 9 p.m. Discourse: "Electric Shadows and Luminescence," by Professor Silvanus P. Thompson, D.Sc., F.R.S., M.R.I. Saturday, May 9th, at 3 p.m. Lecture: "Three Emotional Composers," by F. Corder, Curator, Royal Academy of Music.

SOCIETY OF ENGINEERS.—Monday, May 4th, at 7.30 p.m. Paper: "Hydraulic Rotative Engines," by Mr. Arthur Rigg, Past President. Synopsis:—New Rivals to Hydraulic Engines—Gas, Oil, and Electricity—Great literary attention given to Turbines, and practically none to Hydraulic Engines—Care bestowed upon improvements in economical working of Steam Engines, but comparatively none upon Hydraulic Engines—Water Power remains in a state of primitive simplicity, although it is far more costly than Steam—Cost of pressure water produced artificially—Uncontrolled supply to Hydraulic Engines. General History of Hydraulic Rotative Engines—Bramah—Armstrong—Westmacott, Knowlden, and Edwards—Brown—Schmidt, of Zurich—Hoppe, of Berlin—Walker and Carey—Duckham—Ramsbottom—Brotherhood—Hastie—Greathead—Williams—Walker. Comparison between Hydraulic Engines with two and three cylinders—Diagrams showing rotative effort on crank pin of several types—General Constructive Principles—Revolving Cylinder Types—Variable Power—Governing Hydraulic Engines to uniform speed—Regulating the stroke in accordance with load—Conclusion.

DEATHS.

On the 22nd April, at 13, Newbattle-terrace, Edinburgh, THOMAS MEIK, M. Inst. C.E., in his 85th year.

On the 28th April, at Monkton House, Penarth, HENRY JOHN VOSE, Superintending Engineer Postal Telegraphs, South Wales District, in his 46th year.

THE ENGINEER.

MAY 1, 1896.

THE OUTLOOK IN THE COAL TRADE.

TWO meetings, fraught with issues of vital consequence to the industrial interests of the kingdom, were fixed for April 29th and 30th. The first is that of the Conciliation Board, and the second the Conference of the Miners' Federation. The subject before both is the same—the continuance or non-continuance of the Rosebery Agreement. The Council of the Yorkshire Miners' Association met at Barnsley on the 20th inst.—last Monday week—when the proposals of the coalowners and of the Miners' Federation were considered. Mr. Hewlett, on behalf of the coalowners, proposes that the Conciliation Board be continued "to determine from time to time the rate of wages, on and from August 1st, 1896." Mr. B. Pickard, on behalf of the Miners' Federation, proposes "That the agreement now in existence be continued until the 1st August, 1898." The Council have agreed to recommend the latter proposal and to reject Mr. Hewlett's. This news will be no surprise to those who have followed the narrative of events given from time to time in THE ENGINEER. Of late a large number of miners' meetings have been held in the largest of the colliery districts, and it becomes increasingly evident that the policy prescribed by the Union leaders will be faithfully followed. At one of the most important collieries in the Yorkshire district, the proposal of the Associated Coalowners, relative to the future of the Conciliation Board, was unanimously rejected. This may be taken as typical of the resolutions which are being passed in all the districts. The men have been asked by their leaders to stand by the principle of a minimum wage, with a right to the producers to have a voice in the selling price of coal. These two points form the essence of the proposal put forward by the Miners' Executive, and so far as the decisions of the miners themselves have yet been given, they have been adopted without a single dissenting voice. A noteworthy feature of the meetings has been an equally harmonious compliance with a recommendation from the Yorkshire Executive to advance the rate of contributions to the Union. In the Sheffield district it has been unanimously decided, at one large gathering of colliers, to double the present contribution for the next four months, in order to meet any emergency which may arise when the present arrangement in the coal trade expires. This is the clearest of war notes. It is intended as such, and will be taken in its interest. The general public are paying singularly little attention to the trouble ahead; and with no inconsiderable section the belligerent utterances now so freely heard are discounted as not half so terrible as they read. There is no general expectation of a coal war, whether the Conciliation Board comes to an end or not. The remark is frequently heard, "Oh, the large coalowners will not stop in any case. Their newly-opened and modernly-equipped pits can be made to pay at present prices, and the more of the older ones that go to the wall the better for the others." Neither is there any expectation amongst miners that a demand for lower wages, if seriously made, will be resolutely insisted upon. The probability is that the Conciliation Board will come to an end, that business will go on as it did prior to the Rosebery conference, that the minor collieries, which cannot produce at a profit, will be crushed out in the conflict for contracts, and that the colliers will win the fight for a living wage, as they interpret it, without respect to the values of the mineral out of which the living wage is to come. It is an anomalous and a purely selfish position. It is anomalous, because it sets at defiance all the well-established laws upon which commerce is conducted; it is selfish, because it takes no account of the living dividend, which is as essential to the existence of thousands of investing people as the living wage is for the working collier. It is not clear that this policy will have any other than the usual outcome of its kind. The men make more money per hour during the time they are at work, but they work so much less that they are absolutely poorer at the week end than they would be under moderate concessions. Nor does the evil end there. The British coalowners, handicapped in the cost of production, are being beaten in certain foreign markets; the French Government have decreed that henceforth nothing but French coal must be used in French State establishments—this order has reduced the value of coal sent to France from £231,798 in March of 1895, to £167,969 in March of 1896—and in other directions the trade is being alarmingly attenuated. But the collier looks to his leader, and follows him. There is perfect cohesion in the ranks of the mine workers. Although it would be unjust to speak of the Associated Coalowners as a rope of sand, for they proved themselves strong enough to fight a stern battle, they can never hope to possess the astounding docility of the Miners' Unions. Coalowners have many interests, and their circumstances vary with their seams and the situations in which they are fixed. The colliers have but one interest, and it is the same all round—to resist all reductions. Short hours of labour, and long wages while at it, form the theory of their position; and it must be taken for granted that when the district lodges, on a mere hint from the Miners' Executive, at once decide to double their contribution to the war fund, the men and their leaders may mean a game of "bluff," but it is bluff which means business. And the business is for the men to keep the existing rate of wages for the present, and look for more as soon as they can. The essence of the position for the coalworkers is this, "Let us make the most of the present; get all we can for what we do, and, as for the future, well, let the future take care of itself."

COMPOUND LOCOMOTIVES.

IN another page will be found a letter from an American engineeer, Mr. F. W. Dean, whose name will no doubt be familiar to many of our readers. Mr. Dean asks us why it is that we hold that the advantages possessed by the compound locomotive over the simple engine are best displayed on long runs with heavy trains. We shall answer this question presently. But it is advisable, in the first place, to consider certain arguments and statements advanced by Mr. Dean in a paper read by him last year before a monthly meeting of the American Society of Mechanical Engineers. In that paper Mr. Dean attempts to explain why so much diversity of opinion exists among engineers as to the relative merits of compound and non-compound engines. In effect, he blames not the principle, but the method of applying it. There are, he tells us, certain very good compound locomotives at work in the United States. Probably, he thinks, about one-half of all the compound locomotives in use are bad; and he not unnaturally proceeds to argue that an engine which he has designed is among the best. He tells us in a little explanatory introduction to his paper that "the gains and losses of the compound type of locomotive with reference to the simple type have here been publicly explained and discussed. These features of the compound have been realised by the author, and his designs have been so made as to reduce the losses to a minimum, or to annihilate them, and to make the gains the greatest. Such results are brought about by placing the intercepting valve close to the high-pressure cylinder, by making two oval receivers having large volume and re-heating surface, providing two large openings into the low-pressure steam chest, using a light and efficient double-ported balanced slide valve for the low-pressure cylinder, and having no restricted passages, obstructions, or abrupt turns in passages between the cylinders." As a result he claims a saving in steam of about 20 per cent. We may observe parenthentically that this is the percentage usually claimed by all inventors of compound locomotives, and we venture to add that Vauclain and V. Borries, to say nothing of inventors in Great Britain, will be slow to admit that they have failed to appreciate the value of excellence of detail in working out their designs.

It is not our intention to dispute the accuracy of Mr. Dean's claims; that we shall leave to the ingenuity of our readers. It will be more useful perhaps to give the opinions of most British locomotive superintendents on compound locomotives in general. We naturally hold views identical in all respects. They have often been set forth in our columns. It can do no harm to state them once more, in response to Mr. Dean's request for information. In very few words, then, we say, that whether a compound locomotive will or will not be more economical than a simple engine depends entirely on the conditions under which it is used and on the way in which it is used; and that in this country, so far, the conditions favourable to the compound engine either do not exist at all or only in a modified degree. It would take up far more space than we can devote to the subject to give precise explanations of our meaning, or a sufficient number of examples to demonstrate the truth of our propositions. Putting the facts as concisely as is consistent with lucidity, we may say that the running expenses of a locomotive are not all concentrated in the coal bill. But, leaving this point on one side, we may point out that, other things being equal, the engine which exhausts its steam at the highest pressure will use the greatest quantity of steam in hauling a train. The whole object and purpose of compounding is to reduce the exhaust pressure in a locomotive. It may be said that its object is to work more expansively, and we may write in a learned fashion about heat units and thermal efficiency. All this is very well in its own place. The practical, penetrating truth is that an engine exhausting steam of 100 lb. pressure is wasting more energy than one exhausting at 50 lb. How much more is quite a distinct story, with which we need not just now concern ourselves. The range of temperature theory has been played out as regards the compound engine. Mr. Dean very truly says indeed, "As cylinder condensation is the greatest of all enemies of economy, by using multiple cylinders we invite our greatest enemy to be always with us. It is at least approximately true that cylinder condensation is proportional to surface, other things being equal." It is easy to see that by augmenting the diameter of the cylinders of a simple engine we can cut off earlier in the stroke, and so reduce the pressure at which exhaust takes place. It is a suggestive fact, however, that all attempts — and they have been numerous — that have been made in this country to use cylinders large in proportion to the boiler have ended in failure. The engines have wasted coal. They have not kept time. They have been unsatisfactory in various ways. No doubt this was due in many cases to the drivers availing themselves of the big cylinders, and "running their engines out of breath." But there is more than this. The link motion is a very excellent expansion gear up to a certain point. Beyond that it entails so much compression that mischief is done. The beauty of the compound system is that it dispenses with a very early cut-off in any one cylinder. But the use of special valve gear which has been tried with success at once places the simple engine on a level with the compound engine in this respect.

We may now proceed to reply to Mr. Dean's questions. The benefits of the compound system will be most apparent when an engine is heavily loaded and runs long distances without a stop, simply because these are the most favourable conditions under which it can be used. For let us suppose that we have an engine hauling a heavy train with an initial cylinder pressure of 150 lb. on the square inch, and that the load is such that the pressure has only dropped to 75 lb. on the square inch when the exhaust port opens. If, now, an engine similar in all respects, save that it was compound instead of simple, hauled the train, its greater cylinder capacity would permit us to reduce the terminal or exhaust pressure to, say, 40 lb. But if the load was so light that the terminal pressure in the simple engine was 40 lb., the cylinder capacity of the compound engine would be too great. The exhaust pressure might not be enough to supply draught for the furnace. A contracted blast pipe would have to be used, and the other sources of waste named by Mr. Dean would come into play. We thus find that, according to the conditions, a compound locomotive may be either more or less economical than a simple engine; and, of course, it follows that conditions may obtain under which neither engine would display any advantage over the other. So far, then, it is clear that the more heavily loaded a locomotive is, the more likely is it to be improved in economy by compounding. In the United States loads are usually much heavier in proportion to the size of the engine than they are here, and the exhaust pressures are much higher. Therefore we should expect to find the compound system showing to far better advantage on American than on English railways; and this is precisely what does happen. The late Mr. W. Stroudley would have nothing to do with the compound engine, because he held that the conditions under which his traffic was carried on were not suitable. He always maintained that if the compound locomotive was to be used at all, it ought to be used with very heavy mineral or goods trains on long leads, and up steep inclines. Any one, indeed, who has heard a big goods engine hauling a heavy train up such inclines as Shap, or those numerous enough in Derbyshire, will readily understand that more cylinder capacity would reduce the weight of steam needed per mile. Concerning fast and heavy passenger traffic we have said nothing. Space fails us. But here, again, whether the compound locomotive is or is not better than the simple is purely a question of conditions. Mr. Webb finds that the conditions obtaining on the London and North-Western Railway are favourable to the compound engine. On the other hand, we see that Mr. Holden, on the Great Eastern, says that the conditions on his line are not favourable. The chances are a thousand to one that both gentlemen are right, in spite of the difference in their practice.

On one remaining point we find it impossible to agree with Mr. Dean. He speaks, no doubt, according to his experience; we, according to the experience of British railway men. The compound system is not suited for working stopping trains. Mr. Webb gave a compound engine a thorough trial on the Metropolitan system. His experience was not such as to induce him to build more compound locomotives for such service. In all two-cylinder compounds it is essential that the engine shall work non-compound at starting; and when the distance between the stations is small, the engine is working much of its time non-compound under the worst possible conditions. Mr. Dean holds a different opinion. But he evidently bases his arguments on a type of engine of which we have no experience at this side of the Atlantic. It is, we gather, in experimental use on the New York Elevated Railway. Possibly Mr. Dean will see his way to supply some particulars of its construction at an early date. He says, referring to the question we have just dealt with, "The point here considered is of the greatest importance in suburban and elevated work, for here the compound is peculiarly economical if it is a compound from the beginning. If it is a simple engine for some little time after starting, the greatest part of its peculiar adaptation to the work which requires frequent starting is lost." We confess that we do not see how it is possible to get away with a two-cylinder compound engine without the use of an intercepting or driver's valve; and it appears that so long as this valve is used, so long does Mr. Dean agree with us. It seems then, after all, that there is no wide diversity of opinion between ourselves and Mr. Dean, for such time as we deal with normal compound locomotives. Mr. Dean has, however, a locomotive concerning which we know nothing. That being the case, it is, of course, impossible for us to dispute the accuracy of claims based on its performances. When, for instance, we are told that his engine will always work compound, and yet start a heavy train with much promptitude up an incline of 1 in 55, and that a similar engine—or is it the same? —works with despatch, and certainty, heavy fast suburban traffic with eleven stops in nine miles, we have nothing to say except that we should like to have further particulars of what must be a very remarkable locomotive; and we have no doubt that in this expression of desire many of our readers will unite with us.

PERMANENT WAY.

THE report by Major Marindin, on the accident at Little Bytham, on the Great Northern Railway, lends point to the correspondence which has been proceeding in our columns on the construction of permanent way. The accident in question occurred on the 7th of March, when part of an express train from the North left the rails. Major Marindin attributes the accident to the roughness of the road, which had been renewed. The ballast had not settled, and the rails being out of level, the engine lurched and twisted the track to such an extent that the rear coaches left the rails. It is argued that if the ballast had been good the line would not have sunk, but there is no reason to conclude that the ballast was either worse or better than that on miles of line which carry their loads with perfect safety. "There is no reason," says the report "to doubt that the relaying gang had done their work well, that the rails were properly laid and secured, and were true to gauge and in good line, or that the sleepers were properly packed, but the inspector admits that there was still some work to be done by the ballasting gang in filling up with new ballast, and especially at the sleeper ends outside the outer rail, and it was apparent from an examination of the line that the top ballast was not of first-class quality, being somewhat light and dirty, and that, while in the 4ft. way between the rails it was filled only half way up the sleepers at most, there was a great deficiency of it outside the sleeper ends, which in most places were not boxed in at all. Between 11.40 a.m. and the time that the accident happened, viz., 7.38 p.m., thirty trains, exclusive of the Leeds express which left the rails, had passed over this piece of line, and of these fifteen were passenger trains."

After all has been said, we do not think that this accident goes far to show that permanent way in England is bad. We do not suppose that any railway engineer could be found who would maintain that railway track, even on his own road, is quite perfect; but then absolute perfection is not to be found in our universe, and the wonderful absence of accidents from derailment which attends the working of railway traffic in this country bears splendid testimony to the general excellence of our railroads. The arguments of our correspondents are mainly twofold. One party insists on the necessity for better ballasting, the other appears to care little for ballast and a great deal for track. It is noteworthy, however, that while these last criticise existing roads pretty sharply, they are far from being agreed among themselves as to the substitute. Several advocate longitudinal sleepers and flat-footed rails, others flat-footed rails and cross sleepers. Others, again, hold that if only a good steel chair is substituted for the existing cast iron chair, all will be well.

As there is not the least likelihood that railway companies will make any change whatever in the methods of construction, it is perhaps almost a waste of time to discuss permanent way at all; yet questions connected with it are certainly not devoid of interest. We know that the flat-footed rail on a longitudinal sleeper is entirely out of the question. It has had a very extended trial, and has not succeeded. Our correspondents forget the relations between the rail and the sleeper. The flat-footed rail sank into the sleeper, and could only be kept out of it by interposing packing pieces with the grain across the rail. This was nothing but a makeshift. The difficulties and delays of repair and replacement were intolerable on crowded lines. The defects of the flat-footed rail on the cross sleeper road are well known, although they appear to have been equally forgotten by our correspondents. For the same weights the flanged rail is much less stiff than the bull-head, for reasons which we have recently fully explained, and the rail is more difficult to roll sound and true. But beyond all this there is the difficulty of securing it to the cross sleepers in an efficient way. We have not the least hesitation in saying that a first-class road cannot be made with flanged rails spiked to cross sleepers. The chair road in use in this country is a survival of the fittest. It has been reached after a prolonged history of trial and error. Its sharpest critics are unable to prove in the light of daily practice that it is a bad road. Indeed, their great difficulty is that it is so excellent that it is not easy to see how anything better on the whole can be produced.

We confess that we have some sympathy with the advocates of steel chairs. The normal chair is very cheap, and can be produced with facility by the million in moulding machinery by boys. Chairs at £3 2s. 6d. a ton, or about 1s. 6d. each, do not represent a large outlay even when the percentage of breakages is considerable. The advocates of the steel chair will have to show that money can be saved by adopting it instead of the cast iron chair. It is mainly a question of expense. It cannot be denied that the permanent way on British railways is in the main admirable. We do not say that better might not be produced; but how, and at what cost? This last is the crucial question, and yet it is that on which our correspondents have least to say.

BRITISH-BUILT STEAM YACHTS FOR AMERICAN OWNERS.

FOR individual owners—and all without the United Kingdom—four of the largest steam yachts ever constructed in this country are at present under way in Clyde yards. Three of the new vessels are for American owners, each being about 1700 tons measurement; an advance of 500 tons on the size of Captain H. McCalmont's palatial yacht Giralda, hitherto the most notable craft for size, speed, and sumptuousness, in Britain's pleasure fleet. The three are from the designs of Mr. G. L. Watson, Glasgow, who may well regard the important commissions to design and place the boats as some compensating return for his disappointment over the American Cup contests. The fourth is for Commendatore Ignozes Floris, of Palermo, and will be 1200 tons yacht measurement, and 2300 indicated horse-power, the builders and engineers being Messrs. Scott and Co., Greenock. Her engines will be of the triple-expansion type, and the speed guaranteed is 16 knots. Electric light will be fitted throughout, and the saloons and fittings, of course, will be on a corresponding scale of luxuriance. Perhaps the most noteworthy of the trio of yachts for American owners is the one under way in the yard of Messrs. J. and G. Thomson, Clydebank. This vessel is for the American millionaire, Mr. Ogden Goelett, and will be at once the fastest and most luxuriously appointed pleasure vessel that has ever taken form in Britain. She will measure from the figurehead to taffrail 311ft., while the beam will be about 40ft., and depth 36ft. She will be propelled by twin-screws, driven by triple-expansion engines, supplied with steam from water-tube boilers of the "Almy" type. Her coal-carrying capacity will approach 1000 tons, and under forced draught she will steam 18 knots at sea; her "measured mile" performance, however, being expected to approach 20 knots. In connection with the acquisition of these large steam yachts by American owners—directly, indeed, on account of their being designed and built in this country—it is of interest to learn that a Bill is now before the United States Congress whose object is to shut out foreign-built yachts from the privilege of flying the American flag. It was found in the cases of the British-built yachts Valiant, Conqueror, and others that, though they must be admitted to ordinary yachting privileges as members of foreign yacht clubs, they could not be prevented from flying the "the Stars and Stripes," because there was no penalty against it. In this way they rank to all intents and purposes as American yachts, and American builders and designers are consequently aggrieved. Should the Bill referred to receive sanction from Congress, its effect on the further acquisition of British-built steam yachts may be prohibitive.

SUBMARINE TELEGRAPHIC WORKS.

THE submarine telegraph industry benefits largely by political unrest, as well as by some of the victories of peace, so that it is no wonder that in its past half-year the Eastern Extension Telegraph Company has had a record income. Its total receipts were £311,582, or about 20 per cent. above those for the same period of the preceding year. The gold mining industry of Western Australia gave a heavy traffic to the cables, and thus largely contributed to the enlargement of the receipts. That enlargement enabled a dividend and bonus to be paid of 7 per cent. for the year; and it also allowed of very substantial sums to be paid to reserves. In the half-year 340 knots of the New Zealand cable and 109 knots of the Tasmanian cable have been renewed; and further heavy renewals are intended to be carried out this year. Finally, a payment was made out of reserves which, with previous payments, reserves the sum of £286,043 for the alternative Singapore-Hong Kong cable; and this, added to duplicate and triplicate and other cables that have been similarly provided, brings up to £1,485,000, the sum that has been from time to time paid from reserves built up out of revenue to strengthen the cable system of the company. It is certain that the renewals will be needed for some little time yet, but it may be not unfairly hoped that there will be with the recovery of trade in Australia and in the East, a revenue that will be increased, and that will give the ability to more than maintain even to further extend the great system, which springs from the primal eastern telegraphs, and has carried the nerves of communication to the remotest portions of the empire. It cannot be said that the return over the life of the company has been an inordinate one, though the investment has been increasingly remunerative of late, and that increase may be expected to continue with revival in the trades of the Far East and of Australasia. As yet it has been an industry that has been dependent on a limited number of messages, because of the heavy cost; but by the combination of the Governments and of the companies, it has been possible to cheapen the cost, and probably this may be done yet more in the future, and that there will be a dependence more on the extent of the work than on high charges to cover the interest on the heavy cost of construction.

LITERATURE.

Light Railways for the United Kingdom, India, and the Colonies. By JOHN CHARLES MACKAY, F.G.S., A.M.I.C.E. Crosby Lockwood and Co. London: 1896.

THE author of this portly volume tells us on the title page that it is a practical handbook setting forth the principles on which light railways should be constructed, worked, and financed, and detailing the cost of construction, equipment, revenue, and working expenses of local railways already established in the United Kingdom, the Colonies, Belgium, France, Switzerland, &c. As there has never yet been a time when a good treatise on light railways was more wanted, promises such as those made by Mr. Mackay should ensure the popularity of his book, always provided, of course, that the promises are fairly well kept. The first thing we ask ourselves is what kind of book is most likely to be of service; and the reply is, of course, that one dealing with the various questions which present themselves the moment a light railway in England is mentioned, is that most likely to prove of service at this moment. Now unfortunately, it is just in this class of information that the volume before us is most deficient. Mr. Mackay has collected a great mass of statistics concerning existing light railways. To some extent he has classified his information, but it is all presented to the reader in such a way that it is next to impossible to utilise it for any particular case. Abundant examples of what we mean present themselves on almost every page. Let us take, for instance, the eighth chapter on "Working Expenses." We are told at the outset that "the working expenses of railways depend on several conditions, which vary on different railways." Most people, we believe, will admit the truth of this as a species of self-evident proposition. We want, however, some detailed information as to what the working expenses of a narrow gauge British line ought to be, and we get none. We are told that the Corris Railway in the Isle of Man is worked at 2s. 2d. per train mile; the Easingwold Railway at 1s. 10d.; and the Glyn Valley at 1s. 7d.; but it is obvious that such meagre statements are of no value whatever to a man who wishes to prepare an estimate of the working expenses for a line ten miles long, say, in Cheshire. He will want to know the cost of rolling stock, its depreciation, wages, the quantity of coal used, its cost, the cost of water, and many other things. If Mr. Mackay had obtained and published detailed information of this kind about, say for example, the Corris line, he would have done good service. We are told, again, that "the main results of working the light railways of Belgium is 10d. per train mile, or £204 per mile per annum," and that the expenses are 71·31 per cent. of the gross earnings. Figures of this kind may be of national importance perhaps; but they are not of the least use to the promoter of a line, nor can they be regarded as being in any sense or way aids to the investor. When we attempt to get information on details, we have to hunt all over the book; thus, on page 95 we are told that the cost of working a locomotive on the Glyn Valley Tramway is £13 per week, including all charges. If the price of coal per ton and the driver and fireman's wages had also been stated, little more would have been required to make the information tolerably complete, and therefore useful. Numerous tables are given, but they are very deceptive; the information they supply being far too general to be of much service to promoters or engineers. It is next to impossible, indeed, to arrive, from our author's figures, at any conclusion drawn from analogy as to the chances of profit from any intended line.

Much space is given up to the consideration of light railways abroad—that is to say, in India, Ceylon, Australia, &c.—with tables of prices, &c. But again we are compelled to say that these figures are not, and cannot be, in any way a guide to the engineer in this country. Our author cites for special praise the Moroi line in India, 2ft. 4in. gauge, laid with 30 lb. rails. For twenty-five miles it runs along, and on a good road. It is fairly level. The cost was £1709 per mile. But how is it possible to deduce anything concerning a home line from the results of this? It will be seen that we base our criticisms on our author's title-page. The book does not in any adequate fashion deal with the principles on which light railways should be constructed, or worked, or financed. It does not detail the cost of construction or working. It is not in any proper sense of the word a handbook of light railways; but, on the other hand, if we disregard the title-page altogether, we may say that Mr. Mackay has produced a very interesting volume, of a somewhat popular character, which contains a great deal of general information about light railways, set forth in a very readable way and moderately well illustrated.

One fact comes out very clearly in Mr. Mackay's pages, namely, that it is only under very exceptional circumstances that the light railway really earns dividends for its owners.

The book may be utilised in various ways, its indefiniteness lending it freely to the purposes alike of the promoters and the opponents of any proposed line. Those, however, who desire to have within reach general information concerning almost all the light railway systems in the world will do well to buy Mr. Mackay's book. It may be regarded as the first instalment, perhaps, of a considerable body of literature dealing with the subject. We would advise Mr. Mackay to write a second book, in which he will deal with one or two or even three lines, and supply not only detailed information concerning cost of construction and working, but the reason why the lines do or do not pay. That is the kind of information most wanted at the present moment.

SHORT NOTICES.

Know Your Own Ship: A Simple Explanation of the Stability, Construction, Tonnage, and Freeboard of Ships. Specially arranged for the Use of Ships' Officers, Superintendents, Draughtsmen, and Others. By Thomas Walton. With numerous illustrations. London: Charles Griffin and Co., Ltd., 1896. Price 5s.—Many would like to know something of the construction of ships and the principles upon which their construction, loading, and sailing depend, but the books available are almost all written for those who are, or intend to be, technically instructed for professional occupation. They are either for the shipbuilder, the engineer, or the technical instructor. There is no book for the layman who wishes to gain an intelligent knowledge of the construction, buoyancy, displacement, measurements, stresses, strength, and chief details of construction of hull. This book of Mr. Walton's will remove a want in this direction, and will be found very useful by many who are not quite laymen on ship construction matters.

Handy General Earthwork Tables. By J. H. Watson Buck, M. Inst. C.E. London: Crosby Lockwood and Son. Price 3s. 6d. —This is a pair of tables for easily finding the contents of cuttings or embankments, measured by the 66ft. or the 100ft. chain. The two tables are clearly printed, and are mounted on the inside of a stout pair of covers, or rather a folding cover, like that of a book.

BOOKS RECEIVED.

Willing's British and Irish Press Guide, and Advertisers' Directory and Handbook, 1896. Twenty-third year. A concise and comprehensive index to press of the United Kingdom, &c. &c. London: James Willing. Price 1s.

Commission des Etudes du Port de Montevideo. Présentation de l'Avant-Projet. Rapport de la Sous-Commission. Montevideo: Imprenta y Litografia *La Razon*, Cerro, 57. 1896.

Report of the Results Obtained with Experimental Filters at the Pettaconset Pumping Station of the Providence Waterworks. By Edmund B. Weston. Providence, R.I.: E. L. Freeman and Sons. 1896.

Torpedoes and Torpedo Vessels. By Lieut. G. E. Armstrong, late R.N. Illustrated with a frontispiece by Chevalier E. De Martino, and numerous photographs and diagrams. London: George Bel and Son. 1896. Price 5s.

THE CRYSTAL PALACE EXHIBITION.

THE exhibition which opens on Saturday at the Crystal Palace is full of promise of excellence and interest. The English people have always taken the lead in everything connected with travel, or locomotion from place to place, by land or by sea. At a comparatively early period we possessed the best highways in the world; and probably the same thing may be said with strict truth of our modern roads. On these highways ran vehicles of superlative excellence just before the advent of railways; and the horses which drew them were as good as the coaches and curricles. All this excellence was not attained in a moment; and the Crystal Palace authorities propose to show the world how progress was effected and what shape it has taken from an early period to the present moment, when mechanical power proposes to supplement, if not supplant, the horse. Not only will a representative display of mechanically-propelled vehicles, old and new, be found at the Palace, but a collection such as has never before been got together under one roof of examples of the coach-builder's art, ancient and modern; and besides, an extremely interesting collection of pictures and engravings of the life of the highway. These possess considerable historical importance, as illustrating the dress, customs, and mode of life of our ancestors. Not a few of the exhibits are curious. Napoleon's carriage taken after Waterloo has been seen by countless thousands, but few are perhaps aware that the Duke of Wellington also had a carriage at Waterloo. This has been sent to the Palace by Col. Lionel Tufnell-Tyrell. It was presented by the second Duke of Wellington to Sir John Tyrell. It can be taken to pieces, and then forms three distinct carriages. Another curiosity is the original brougham, or at least of all that is left of it, namely, the body. Lord Brougham used it at his seat, Brougham Hall, near Penrith, Cumberland. It appears in a very dilapidated state, although the timber is still sound. The coat of arms and coronet on one of the panels are still visible. It was built about 1840. Another relic is the Queen's first carriage, built by the predecessor of William Cole in 1828, and driven by her Majesty at the age of twelve and onwards, in the gardens of Kensington Palace. This carriage was drawn by a donkey, and her Majesty at the present day still uses a similar carriage which is drawn by a donkey.

In the present day we are prone to forget the work done by our predecessors in facilitating transport and intercommunication. Those, however, who are familiar with the works of the earlier engineers understand how great was the interest displayed by such men as Telford in the construction of our magnificent coach roads. The engineering difficulties overcome were very considerable, and the perfection attained has never been impugned. The mail coach was a remarkable vehicle—a vehicle in all respects constituting a survival of the fittest, and an exquisite adaptation of means to an end. It was made the subject of most elaborate experiment in draught; and the excellence of its material and workmanship, combined with lightness, rendered it ultimately a real marvel of constructive skill. It is doubtful if at this moment an old Royal Mail, say, of 1825, is in existence, but Messrs. Holland and Holland exhibit a coach which is very nearly as old, and may be taken to represent, perhaps, the ultimatum of the art of building mail coaches. It was built about 1830 by Wright, or Waud, who were then considered the chief builders of mail coaches, and it has been in Messrs. Holland and Holland's possession for nearly thirty years. Only two years ago it went to Ascot; but now it is past work.

Messrs. Holland and Holland tell us that when this coach became their property, it was a regular Royal Mail, having only the seats behind the box seat and one seat for the guard at the back; and the latter had a blunderbuss, &c., in a box before him, where the back roof seat is now placed. This coach, before being altered, had gold stars painted on the quarters and doors, and "V.R." in big letters, this having been the fashion with all Royal Mail coaches. The hind boot opened at the top, under the guard's feet, so that the mail bags as they were thrown up could be easily dropped into the depths below. In order to accommodate the letter-bags, which, as the postage was gradually lessened, became more and more numerous, the hind boot of the carriage was made deeper than usual, and differing from the general plan, as our readers will notice on looking at this coach, the boot was brought out flush with the body of the coach. In order to allow of the extra depth of boot referred to above, the hind axle was bent downwards. As it stands to-day, with the exception of the wheels having been renewed from time to time, and the addition of the two hind seats, this interesting coach is precisely as it was sixty years ago.

Besides complete vehicles there will be a large collection of models and examples of various inventions applicable to locomotion, such as spring wheels, india-rubber tires, and a multitude of appurtenances far too numerous even to mention in detail. From H.M. War Department comes a very interesting collection of models from the Rotunda Museum at Woolwich, including such things as models of two Irish cars fitted for conveyance of ammunition, an ancient sling wagon upon curious springs, a carriage and two pontoons complete—Blanshaw's—a travelling forge wagon and limber, a gun carriage for a 33-pounder siege gun, a 12-pounder ammunition wagon, dated 1732, a crane constructed on a gun carriage—French—and a store cart dated 1732.

For our readers probably the most interesting feature will be the exhibition of self-propelled carriages in the building and the grounds. It is impossible that these carriages should be numerous, because they do not as yet exist, and of those shown the major part have already been fully described in our pages.

Nearly every method of mechanical propulsion will be shown, from the handsome little traction engine with wood tires, shown by Messrs. Burrell, of Thetford, to the small self-propelling vehicle, built in 1887, and called the Petrol cycle, shown by Mr. C. T. Crowden, and supposed to have been the first oil-driven motor vehicle ever constructed. The Randolf steam omnibus has been brought from the Patent Museum at South Kensington, and we regret to have to add that neglect and corrosion have been suffered to play havock with it. Among others who have sent or promised to send horseless carriages are Mr. Ward, who will exhibit four electrical omnibuses or vans; the Universal Electric Carriage Syndicate, Arnold Motor Carriage Co., Decauville et Cie., Emile Delahage, Louis Delmar, Gerhadt and Ochme, A. F. Hammer, F. Leitzmann, Lepape, Sir David Salomons, Bateman, Des Vignes and Terry, L'Hollier, Gascoine and Co., the Steam Carriage and Wagon Co., the Britannia Co., &c. &c.

What remains to be said about them we shall say in succeeding impressions. The exhibition, like all exhibitions, will not be complete on the opening day, and that has certainly not been the fault of the Crystal Palace Company, or Mr. Gillman, or Mr. Sennett. It is, of course, impossible to do more now than speak of it in general terms, and to add that it will be opened by the Lord Mayor on Saturday, at 2 p.m.

THE LONDON, CHATHAM, AND DOVER RAILWAY COMPANY, in conjunction with the Northern of France Railway, announce that an important new service from London to Cologne, Berlin, and St. Petersburgh, will be brought into operation once a week from May 9th. Passengers will leave Victoria at 11.0 a.m. on Saturdays, and travel *viâ* Dover and Calais, Brussels, and Berlin, reaching Cologne at 11.30 the same night, Berlin at 8.40 the following morning, and St. Petersburg on Monday afternoon at 3.50 p.m. The trains will be composed of sleeping cars and one dining car. This service will effect a saving of nine hours, compared with the ordinary through trains, and will give an excellent and rapid means of reaching Berlin by the Calais route. There will also be a special service on the same day *viâ* Ostend, and passengers leave Victoria one hour earlier, viz., 10.0 a.m. A similar service will leave St. Petersburg on Tuesdays for the return journey, by both routes.

BRICKPAVING.—The specification for brick paving adopted by the city of Peoria, Ill., for the coming year's work, includes the following:—The foundation is to be 6in. of concrete, composed of one part natural cement, 1½ parts sharp sand, and four parts broken stone concrete, covered with a 2in. cushion of sand. The size of the bricks is to be 2½in. by 4in. by 8in., or 3in. by 4in. by 9in., and they are required to withstand the following tests:—(1) A transverse test flatwise, in which they shall show a modulus of rupture of 2200 lb. per square inch; (2) an absorption test, in which, after forty-eight hours' immersion, they shall show an absorption of not more than 2 per cent. of their own weight; (3) an abrasion test, in which twelve bricks are placed in a cylindrical rattler, 24in. by 3ft., with 300 lb. of smoothly-worn scrap iron, in pieces varying from ¼ lb. to 5 lb. weight, and revolved one hour at fifteen revolutions per minute, after which the loss by weight for the smaller brick is to be not more than 9 per cent., and of the larger brick not more than 7 per cent. The cement is to be tested for fineness, time of setting, soundness, and tensile strength. In the pavement the bricks are to be set on edge in rows running transversely across the street, except at street intersections, where the rows shall make an angle of 45 deg. with the curb lines. After laying, the bricks are to be settled by a roller weighing not less than 250 lb. per lineal inch, or by tamping by a 60 lb. rammer on a 2in. by 12in. by 12ft. plank. The joints are to be filled with sand.

MIDLAND INSTITUTE OF MINING ENGINEERS.—A meeting of the members of this Institute was held on Saturday, 18th April, in the Chemical Lecture Room, Firth College. Mr. John Nevin, president, occupied the chair, and amongst the gentlemen present were:—Mr. A. M. Chambers, J.P., Mr. G. B. Walker, J.P., Mr. T. W. Jeffcock, J.P., Mr. H. Bonser, Mr. E. W. Thirkell, Mr. A. A. Atkinson, Mr. H. Nash, Mr. T. W. H. Mitchell, Mr. A. W. Bennett, Mr. R. Kennedy, Mr. W. Washington, &c. A discussion on Mr. G. Blake Walker's paper on "The Roth Method of Firing Shots" was opened by Mr. Shea, with a series of experiments, showing the means by which explosion of the cartridge is caused in Dr. Roth's system. He said it seemed to him to be a very good and serious attempt to avoid the use of fuse in mines, but he could not see that it possessed any great advantage over the electrical method of firing shots. A practical objection appeared to him to be the danger of the leaden tube getting closed up. The leaden tube connecting the bottle outside with the detonator in the shot hole was of very small diameter, and in stemming the shot a slight shot might cause the hole to be closed up so that the chlorine gas could not get to the detonator, and there was also the possibility of some chemical change taking place in the mixture which might involve danger when it came to be used in the mine. In replying to a vote of thanks, Mr. Shea said that chlorine monoxide, though a dangerous gas, was perfectly harmless and safe used in the way Dr. Roth suggested. Replying to Mr. Bennett, Mr. G. B. Walker said it was usual to carry the tube only just through the shot hole; two minutes elapsed before the shot was fired, so that there was plenty of time to get away. The system, he understood, had been used in Westphalia with very satisfactory results. After some remarks from the chairman on the Acton Hall sinkings, a short discussion arose on Professor Lewes' paper on "Mining Explosives." Mr. H. Bonser, in reviewing the position, said a perfectly safe explosive had yet to be manufactured, and it followed that mechanical methods must be resorted to in this direction. Nothing safer than the water cartridge and the gelatinous cartridge had yet been employed, and the committee charged with the subject might extend their observations by firing explosives surrounded by water in future experiments, and he had little doubt the problem of complete safety would be solved. Professor Lewes said a small quantity of carbon monoxide would make a mixture of coal dust and air very explosive, and that by igniting carbonite in a small bomb and sprinkling coal dust into it the whole was readily ignited by a lighted match. The experiments carried out by the committee of the North of England Institute did not bear out this contention, and actual experiments outweighed all theories. With any high explosive the quantity of carbon monoxide produced by a shot was perfectly inappreciable in a working place. Mr. G. B. Walker and Mr. Shea spoke briefly, pointing out that in given circumstances carbon monoxide might cause an explosion in coal dust, Mr. Bonser holding it was not a practical question. A discussion on Mr. Rankin Kennedy's paper on "Electrical Machinery for Mines," was adjourned.

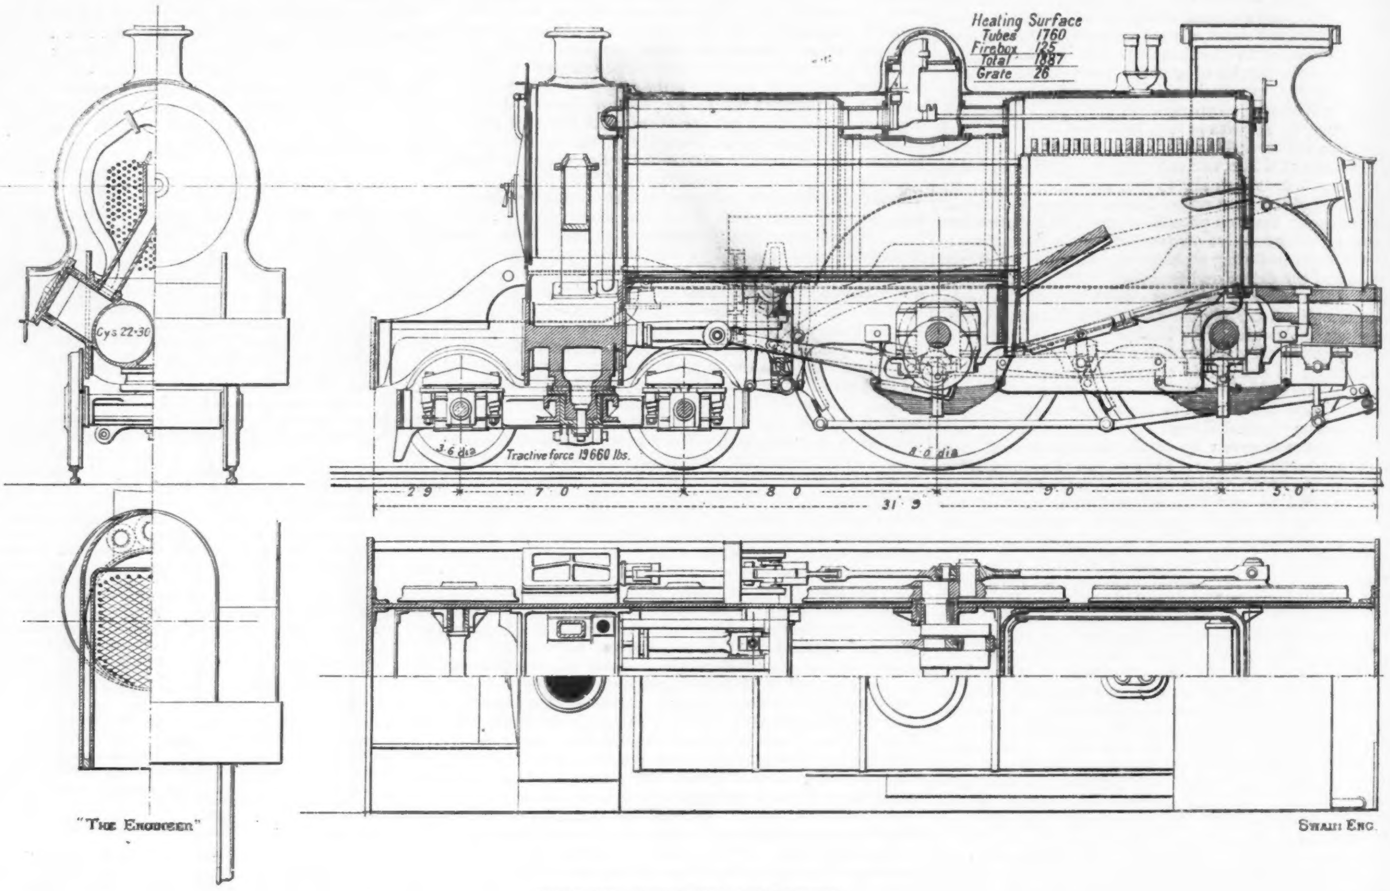
LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

COMPOUND LOCOMOTIVES.

SIR,—In furtherance of my letter published in THE ENGINEER March 20th, I now enclose print of the large locomotive. You will see that it is designed on the lines aid down in your article of March 13th. Having made some of the preliminary drawings of Winby's patent locomotive when with Messrs. Hawthorn, Leslie and Co., I concluded that it was not an engine that would commend itself to railway engineers, also that an engine could be designed of equal or more power without the complication and cost. The greatest difficulty was the boiler, but, as will be seen from the drawing, this was overcome in a very simple manner.

The fire-box is of the ordinary raised locomotive type, the bridge stays being arranged transversely on account of the length. From the fire-box shell the barrel is of ordinary diameter, to go between the driving wheels, it is then increased in diameter and joined to the smaller part by a circular flanged plate, the flat surface of which is supported by the diagonal stays which support the smoke-box tube plate. On the smallest diameter of barrel the dome is placed, which is connected to the fire-box shell by a steam-pipe, through which the regulator rod passes. The regulator steam-pipe is connected to the dome and flange plate of the barrel, and there are two steam-pipes—one on each side of regulator pipe—connecting the dome with the front part of the barrel. The large diameter of barrel and increased height of fire-box shell give ample steam space, and the smallest part of the barrel is filled with tubes, and the dome, being above, takes the steam. The fire-grate, being sloped, can be carried over the trailing axle, and this gives the necessary grate area. The height of boiler is greater than usual, but there are engines running in this country within a few inches of it, but in America there are many locomotives running at high speed with much higher boiler centres on the same gauge.



BAGULEY'S COMPOUND LOCOMOTIVE

The inside cylinders are cast, together with the valve chests outside the frames, at an angle of 30 deg. This allows ample room for the steam and exhaust pipes, and is necessary for the valve gear, which is Baguley's patent, and in the engine illustrated is worked from the coupling-rod pin or driving axle. It consists of a valve connecting-rod, the driven end of which works a pendulum lever, the end of which carries the radius link, and gives the lap and lead movement by lifting the radius link from side to side. The radius link has an arm which is connected to the valve connecting rod, and the horizontal vibration of the latter rocks the link or its centres, and gives the port opening and cut off. The gear has been fitted on over thirty locomotives—tank engines—and gives excellent results in practice, the wear and tear being reduced to a minimum.

The engine frames are parallel from end to end, and the whole of the motion, &c., is on straight lines throughout, without overhanging parts or cranks. The bogie is of the cradle type, and with its wheels swings completely under the frame, so that the engine may pass round sharp curves with safety.

The whole idea being to design a locomotive that could be constructed for about the same price per ton as existing engines, and to follow, as far as possible, ordinary main line practice, keeping the outside appearance similar; the total width, height, and running weight per wheel are such that it could be run on any of the leading English lines, the weight per pair of coupled wheels not being greater than what is daily run by single expresses.

Stafford, April 14th. ERNEST E. BAGULEY.

SIR,—Your recent article on triple cylinder locomotives I have read with interest, but must take exception to your statement that the compound locomotive will do best on a long straight run, and presumably at high speed. I take the view that this is the kind of service in which the compound will do the poorest and the simple engine the best. Quick work enables the simple locomotive to work its steam most expansively, and with minimum losses, while with compounds this service increases the loss of work between the cylinders, and gives less opportunity for re-heating in the receiver. This loss of work has often been in poorly-designed compounds sufficient to neutralise the gains from compounding, so much so that the compounds referred to have saved no water, although they have saved coal by better evaporation.

In suburban work and heavy freight work the compound saves most over the simple engine, because it expands its steam more than the simple, and exhausts at a lower pressure. When a simple engine starts it is necessarily for some time very wasteful, while the compound engine is fairly economical from the start, and much more so soon after.

I should be very glad to have you state at length what your reasons are for thinking that the compound locomotive has its greatest advantage over simple locomotives in long fast runs.

I enclose a copy of a paper of mine upon compound locomotives, read before one of the irregular meetings of the American Society of Mechanical Engineers. F. W. DEAN.

53, State-street, Boston, Mass., U.S., April 17th.

BOILERS FOR ELECTRIC LIGHT STATIONS.

SIR,—From a perusal of your recent columns, your readers will have concluded that only two types of boilers—the water-tube and Lancashire—are in actual use for electric light stations and suitable for such. This must be our excuse for troubling you with this letter.

The marine boiler of the single-ended Scotch type, with Serve tubes and the Ellis and Eaves suction draught, possesses all the features specially desirable for this purpose. It is giving complete satisfaction, and a repeat order is now being executed for the extensions in one installation. It is being fitted in three others. At our own works, where the demand for steam is also unequal and intermittent, similar boilers have been at work for nearly five years, day and night, with the exception only of Sundays and holidays. The total plant on this system in our own works represents an evaporation of over 150,000 lb. of cold water per hour.

This combination occupies much less ground space for a given horse-power than the water-tube boiler of the types in use or the Lancashire boiler, even when no economisers are used. At the same time the efficiency of the installation is very high, no less than 72½ to 75 per cent., even when burning at the rate—familiar enough to us, though strikingly high to those unacquainted with it—of 45 lb. of coal per square foot of grate, 5ft. 8in. long, exclusive of dead plate. The rate of draught is varied instantaneously at will from the lowest to any intermediate or the highest rate, without damage to the boiler, as proved by the experience named. Thus one boiler, 10ft. 6in. diameter by 10ft. 6in. long, occupying, with suction fan and engine—placed usually behind it on the ground—a space of 19ft. by 12ft., will easily give at this rate of efficiency an evaporation of 12,000 lb. of cold water per hour for the period of the maximum load, or even 15,000 lb. with special coal, whilst pressure can be maintained with a few pounds of gas coke per hour when no service is required. At the intermediate rates of combustion the efficiency is naturally still higher, but the other types of boilers named are not equal in efficiency, at any rate, of combustion, to the efficiency at our highest rate. Incidentally, any kind of coal can be burnt without smoke. High chimneys are not required, but only such as are insisted upon by local authorities to carry the smokeless gases away at sufficient height to be no nuisance to the immediate neighbourhood. There is no brickwork. The boilers are above ground and accessible all the time.

Thus from a given ground area this system enables a greater total evaporation to be obtained, with a higher rate of efficiency than with any other system at present in use, whilst the control of power is absolute. We have removed over fifty of the large number of Lancashire boilers we had, partly for the sake of the space, partly for the economy. Pea-nuts are very convenient fuel, and the boilers will burn anything which can be burnt in any boiler.

(JOHN BROWN AND CO.)

Sheffield, April 22nd. F. GROSS.

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—I regret that through absence from home I did not see, till last week, the leading article in your issue of April 3rd, in which you honoured me with so much attention in connection with the discussion, at the late meeting of the Institution of Naval Architects, on the theory of circulation as set forth in Professor Watkinson's paper on water-tube boilers.

I have now carefully read that article, and I find so great divergence between the views I entertain as to the causes of circulation and those which you have ascribed to me, that I cannot help thinking that the discussion alluded to, or at least the part which I was permitted to take in it, must have been very imperfectly reported to you. I am the more led to this conclusion because, in your report of the discussion, the summary of my remarks is limited to two sentences, the first of which is misleading, and the second refers to a matter to which I certainly did not allude at all.

Under these circumstances, and as you kindly invite a reply from me, you will, I hope, allow me to state briefly the substance of what I really did say on the occasion, my memory being refreshed by a copy of the shorthand notes now before me.

Professor Watkinson had considered three stages of circulation:—(1) Before steam was formed in the up-tubes. (2) When bubbles of steam were being formed, but not in sufficient quantity to break the continuity of the water. (3) When very rapid generation of steam caused steam or foam to interfere with the continuity of the water. He stated that in the two extreme cases—(1) and (3)—the cause of circulation was the difference of the density of the risers and down-comers.

With this I entirely agreed, but I differed from him in that I ascribed the same cause to the intermediate case (2); also, whereas Professor Watkinson assigned a different cause to this case, viz., the "entraining action" of the bubbles rising through the water in the up tube. It is this "entraining action" or "frictional drag" of the bubbles as they rose, or rather, were forced, through the water which I took exception to as a cause of circulation. I pointed out that the upward drag of the bubbles on the water is necessarily accompanied by an equal and opposite drag on the bubbles by the water through which they are moving. Now the observed effect is that the whole contents of the up tube—water and bubbles together—are being lifted bodily. The action and reaction between the two parts, the bubbles and the water, which neutralise each other when the motion of the whole mass is considered, are powerless to lift the whole mass bodily. Surely Newton's Third Law of Motion teaches us that no internal actions between parts of a body, simple or complex, can move that body as a whole. Were it otherwise, there would be some hope of success for the boy who tried to lift himself over the fence by tugging at his boot laces.

Professor Watkinson did not improve matters by appealing to an experiment wherein he produced circulation by dragging a row of beads on a string up and down a tube of water. Here he introduced an *outside* force, the pull on the string, and the experiment, I submit, has no bearing whatever on the results of the mutual action of steam bubbles and the water round them.

It certainly seems to me that the superior pressure in the down-comers, due to the greater mean density of their contents, is a sufficient cause of circulation, not only in Professor Watkinson's extreme cases (1) and (3), but also in the intermediate case, and, indeed, in every case of natural circulation in water-tube boilers.

Allow me now, Sir, to allude to an argument which you advance in your own article, with the object of disproving the above simple contention. You imagine a diaphragm across a vertical U tube, and at the lowest point of it, dividing the water in one leg from that in the other, and you say that "So long as there is a column of water, no matter how thin or how light, extending from the top of the riser to the diaphragm, no movement can take place, the hydrostatic pressure being the same on both sides of the diaphragm."

This is certainly true as a hydrostatic problem, or as long as everything is at rest, but permit me to point out that the motion of water, and, therefore, circulation in water-tubes, is governed, not by hydrostatic laws, but by the laws of hydraulics.

Let me put the matter differently. We will suppose our vertical U tubes, connected with a water-receiver at the tops, to contain solid water in the right leg and some immersed bubbles in the left leg, which bubbles are by mechanical means in some way held down and prevented from rising. We have the same pressure near any one of the bubbles in the left leg as at the same level in the right leg, and everything is at rest. But now let the bubbles go, and instantly the water around them acquires velocity, and, in so doing, loses pressure, the "pressure head" being partly transformed into "velocity head," according to the well-known hydraulic law. The pressure is now less in the left leg than at the same level in the right leg, and a flow is at once set up from high-pressure to low-pressure, or from the right leg downwards towards the left. I hope this is clear, and that it may appear to you, Sir, as it does to me, to be a sufficient theory of circulation, consistent with the one previously discussed, but from a different point of view.

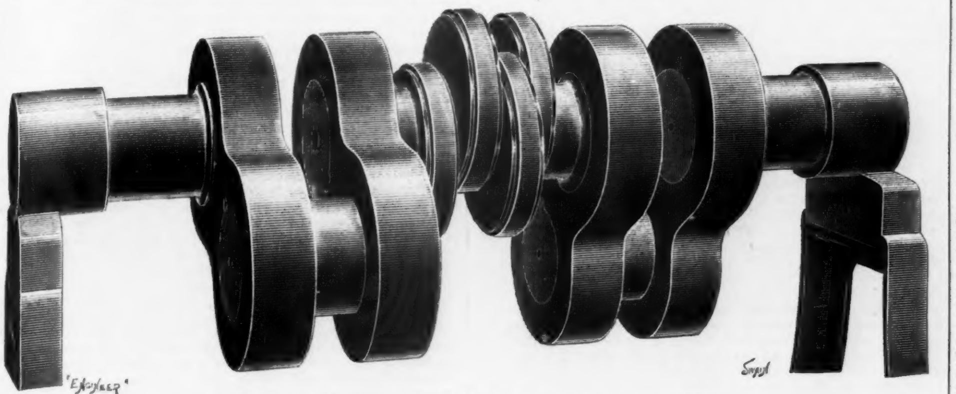
I have written this letter, Sir, in response to the invitation conveyed in the last clause of your article, and I venture to hope that you may find space for it in your next issue of THE ENGINEER.

Royal Naval College, Greenwich. CARLTON J. LAMBERT.
April 28th.

[We hasten to express our regret that we have misunderstood Professor Lambert's words. The point, however, is of very small importance as regards the phenomena. The difference of opinion on the main fact remains. As to entraining action, if Professor Lambert is right, no body moving through water draws any after it; and a ship, for example, has no following wake; a boiler never primes, and steam is always dry. We must ask Professor Lambert to reconcile his denial of all entraining action with his hydraulic theory. We gather that he holds that the bubble-containing column rises, because the bubbles when rising cause a loss of pressure at the base of the column, although they would not if they were at rest. Professor Lambert overlooks the fact that the bubbles are pushed up from below, and that this pushing results in a reaction at the place of the diaphragm. "The pressure is now less in the left leg than at the same level in the right leg," says our correspondent. Why is it less? We strongly suspect that our correspondent uses the word entraining in a somewhat different sense from ours. We shall be glad to hear further from Professor Lambert on this subject.—ED. E.]

A BUILT-UP LOCOMOTIVE CRANK SHAFT.

SIR,—You may think the enclosed photograph of a built-up locomotive crank axle of sufficient interest to your readers to illustrate in your journal. With proper tools it is not costly to produce, and enables us to get more effective surface for the big ends than in the solid crank, owing to there being no radii at each end of the crank pin. The pin and also the axle-box bearings are case-hardened, which gives a more durable surface. The excentrics and the middle are turned out of the solid.



BUILT UP LOCOMOTIVE CRANK AXLE, L. & N. W. RAILWAY

The crank from which the photograph is taken was for one of our engines with 17in. cylinders by 24in. stroke.

Crewe, April 22nd. F. W. WEBB.

THE LIQUEFACTION OF GASES.

SIR,—If your correspondent "Cryos" will first make himself acquainted minutely with what has been done, and will then ask me any question that puzzles him, I shall be happy to give him any information I can. At present, however, it is quite clear that he has failed to understand the Hampson process. Indeed, if "Cryos" is right, Dr. Hampson has never liquefied a gas at all, and my eyes have deceived me.

"Cryos" cannot understand how great cold can be produced in an apparatus which has lost no heat. The explanation is simply that two different temperatures not only may, but do constantly exist in the same body of gas. Take, for example, the temperature, say 4000 deg. Fah., of the gas entering a flue of a locomotive, and 600 deg. Fah. the temperature of the same gas at the other end of a tube 10ft. long. In the Hampson process we have a tube more than 10ft. long. At one end the temperature is some 250 deg. or 300 deg.; at the other it is – 180 deg. or – 200 deg. The difference is probably less than 500 deg. in this case. It is probably at least 3000 deg. in the case of the locomotive flue. There is surely no matter for wonder in the difference in the Hampson apparatus?

It is a simple matter of calculation how much the Joule effect can accomplish, and for air or oxygen it is too little to take practical account of. With carbonic anhydride it is about five times as much as with air.

"Cryos" is under the mark when he says that the expanding air does work against the atmosphere. It does very much more. Expanding in the Linde apparatus from 300 atmospheres, or 4500 lb. on the square inch, into 100 atmospheres, or 1500 lb. on the square inch, it helps the compressing pump during the suction stage in a way which "Cryos" will readily understand; but then all this work reappears as heat at the compression side. It represents so much less fuel burned, but it does not represent any loss of heat outside the apparatus.

The regenerative cold aspect of the question is really too simple, I think, to need further elucidation.

Finally, I may call "Cryos's" attention to the circumstance that he has not given a scrap of evidence that any energy in any form escapes from the apparatus. All the efforts, indeed, of the user are expended in preventing, with indifferent success, energy from getting into it from the external surroundings in the shape of heat. Even if the Joule effect was applicable—which it is not—that would not determine the escape of energy from within to the external world.

I have no desire to inflict a long mathematical disquisition on your readers, when nothing of the kind is really necessary. But it may not be out of place to refer "Cryos" to Hirn's treatise on thermodynamics for a fuller handling of the porous plug experiment than is to be found in Clerk Maxwell, and to page 114 *et seq.* of "Thermodynamics, Heat Motors, and Refrigerating Machines," by De Volson Wood, published by John Wiley and Sons, New York, in 1889. ZERO.

April 27th.

PERMANENT WAY.

SIR,—I trust you will afford me the opportunity of saying another word upon the subject of "Permanent Way," especially as Major Marindin, in his report on the Little Bytham accident, corroborates my views in more than one direction. I agree with the Major that no fault is to be found with the "individual in the matter of inspection, and I consider it lies at the door of those only, who, by their attainments and position, are quite capable of investigating the effects produced on the so-called permanent way, by the introduction of a very heavy rolling stock, with the disposition of the weight and the high speed at which it is run."

It seems to have been forgotten that the only effective connection between the rail and sleeper and the "formation" of the road is due almost entirely to the weight applied as the load rolls over it, producing besides a lot of effects evidently not yet challenged, even if suspected. The weight of the rails and sleepers themselves, including the few barrow loads of ballast cast upon them, may be taken as *une quantité négligible;* but not quite so the ballast, which might be put between the sleepers and at their ends.

Where the lives of her Majesty's subjects are concerned, and considering that I myself might unfortunately have been a traveller with the train that came to grief at Little Bytham, I feel that I have a right to make myself heard by the greatest number on a matter that I know something about; and I attempt this, too, because I think the last word has not yet been said upon it, and that in the interest of all the subject cannot be considered as closed.

I have no idea of criticising the report of Major Marindin, but I do ask why any one should suggest—the realisation of which only adds greatly to the inferred shortcomings of the "practice" condemned—that a lighter train, certainly not going at half the speed of the train which followed it, should have the effect of "distorting a road," and preparing it for the derailment of a following train, far more capable in itself of producing the necessary distortion? Why suppose the lurching felt by the locomotive of the latter train, not to have been the direct result of the very much heavier blow inflicted by a much greater weight, multiplied into a greatly increased velocity? If the previous train did perform the sinister work, then the possibility of the succeeding train doing it was doubly imminent.

There are numerous items of possible improvement of the permanent way of a railway, beside the very good one of the steel chair—if only engineers will think so, there's the rub—which in time will doubtless be adopted, and the sooner the better—I say for all concerned. J. W. WILKINS.

15, Lilford-road, S.E., April 28th.

SIR,—I see a correspondence is beginning on this subject, and especially *re* steel *versus* iron chairs.

Is not the proper solution of the matter the abolition of chairs altogether? Our use of railway chairs seems contrary to the general practice of other countries, and it must lie with those who support the chair system to show us its advantages. Your readers who were brought into contact with the leading representatives of the United States and other countries at the International Railway Congress will bear me out in saying that while they admired the excellence of our permanent way they were unanimous in condemning our chairs as making the road too rigid and hard. The only result of using chairs—beyond extra expenditure—would seem to be to make the rails a continuous bridge supported on a hard surface, with a very small bearing surface; instead of placing the rails on the sleepers which gives the whole width of the sleeper as a bearing surface, and this surface one which is slightly elastic, and which therefore mitigates the blows and noise inseparable from wheels running at speed on metal.

But, as I have said, perhaps someone will start a discussion by telling us the advantages of chairs; the disadvantages are manifest. NORMAN D. MACDONALD.

SIR,—Your correspondents of last week make some strong statements. I have seen the chair referred to—Muirhead's, of Glasgow—and although not prepared to endorse the claims of your correspondents, I am sure the new chair will get a fair trial. It has several points in its favour. (1) It is said to be cheaper, that is, a mile of road can be laid at less cost with this than cast iron. (2) It is of the same pattern as the old chair, taking the same key and spikes, so that no special arrangements have to be made for its adoption. (3) Being half the weight, the platelayers will be all in its favour. If, as is stated, it is found to be cheaper than cast iron, that will be its greatest claim, as, unless it can meet its old opponent in price, it will have no chance, as, however willing railway engineers may be to introduce improvements, they must satisfy the treasury of the railways. Every former attempt in producing a steel chair has failed in this particular. Therefore, it remains to be seen if the distribution of metal adopted in this new one can make it a commercial as well as a mechanical competitor with the old chair. INSPECTOR.

Leeds, April 28th.

SIR,—Major Marindin's report on the Little Bytham accident, which has just been issued, states that "owing to the deficiency of ballast the road was unfit for trains to run over at full speed."

I think it should be generally known that in America and some of our colonies a system of ballasting is adopted by means of specially designed hopper wagons and ploughs, whereby the process is greatly simplified, and a train load of ballast can be deposited, spread, and trimmed in less than ten minutes, with the attendance of only one or two men. This system has been adopted in this country by the Great Western Railway Company, where its advantages are recognised and appreciated, and also by the Glasgow and South-Western and Great North of Scotland Railways; but the majority of our English railway companies hold aloof, and, with true conservative feeling, prefer to adhere to their antiquated and costly practice.

It can hardly be doubted that if such a method of ballasting had been in vogue where this accident occurred there would have been no occasion or inducement to defer the operation of ballasting until the necessary time and men could be found to do it, the catastrophe would have been averted, and a lamentable loss of life have been prevented. JAMES FFORDE, M. Inst. C.E.

17, Victoria-street, Westminster, 24th April.

SIR,—Two correspondents have, in your issue of 24th inst., advocated the use of steel chairs, although it is not quite clear whether cast or rolled steel is recommended. In either case the question of cost should not be disregarded; and it is scarcely likely that the cast iron chairs now used will be replaced by steel ones, unless some distinct advantage on the score of economy can be shown.

No doubt the excessive weight is objectionable in more respects than one, and it arises—(1) from the great bearing area necessary to prevent crushing into the wooden sleepers; and (2) from the great thickness of metal required under the rail to resist cross strain in the chair.

By using the system described and illustrated in my letter, published in THE ENGINEER of 25th October last, the weight of cast iron necessary for the support of an 85 lb. rail can be reduced to 32 lb., without any sacrifice of strength or alteration in the present method of keying; and I do not think it would be easy to improve this in either efficiency or cost. I should be glad to furnish either of your correspondents with further particulars if desired. JAMES WHITESTONE.

113, Queen Victoria-street, E.C.,
April 28th.

SIR,—Your correspondent, "For the Platelayers," in his suggestion for the use of steel chairs instead of the present heavy cast iron ones, is partly answered by Mr. James Andrew, but these gentlemen do not seem to be aware that there are some steel chairs on the Glasgow and South-Western Railway, outside St. Enoch Station, which were laid there eighteen months ago, and are as good as ever to-day. From inquiries in Glasgow, I find these chairs are made under Mr. R. M. Harrison's patent, weigh 18 lb. each, and are pressed out of a piece of tin-plate bar. I am also informed that the Great Northern Railway, North-Eastern Railway and Caledonian Railway are using these chairs on parts of their lines, and as they seem to me to be practically unbreakable, and have the merit of elasticity, which cast iron has not, I think they would be just the things for the platelayers, your correspondent included. S. E.

Birmingham, April 27th.

HORSELESS CARRIAGES.

SIR,—It seems to me a mistake to allow one carriage to draw another at a high speed. You cannot get power out of the driving wheels unless you have great weight on them, and it would practically allow the present traction engines with their heavy trains behind them to occupy the roads and run at a dangerous speed. If two vehicles were hinged together and their length did not exceed 20ft. it might be reasonably safe, but the utility of it is questionable. As to a breakdown, one vehicle could be sent to bring home the broken carriage, if it observed the rules of a red flag and four mile speed. If Parliament allows a total weight of four tons for the carriage and its load, and a maximum speed of ten or at most twelve miles an hour, it is all we want with a maximum length of, say, 20ft. or 22ft. A landau and its pole is about 20ft. long. G. A. HAIG.

SIR,—In reading over the conditions of the road carriage competition I observe that you have omitted to stipulate that the vehicles shall be sufficiently powerful to ascend the steeper gradients, and I venture to think that this should be in some way incorporated in these conditions. The gradients on most roads are admittedly seldom above 1 in 14-15, but any one acquainted with the country, and venturing into the hilly districts, will be faced with grades up to 1 in 8. It may be news to you, but in Scotland in the northern parts and on the main lines of highway in the highlands 1 in 10 is not infrequent. If you will consult the map you will find that on the Inverness and Wick road there are big hills—that at Berriedale being, I think, 1 in 9, with a nasty turn on it. The Perth and Braemar road, with the "Devil's Elbow," a fearful double turn, shaped so Z, is on the slope of 1 in 9, and on account of its altitude the surface is abominable. The Glencoe road is 1 in 10 at its steepest point, and has also very rough surface. Were these side roads it would not matter much, but seeing they are high-roads, and the gradients being necessities, mostly from the physical features, it is scarcely likely that a remedy is possible or can be expected. Off the main lines of traffic there are, of course, any number of other hills of equal steepness leading to the more out-of-the-way districts, but they nearly all lead to the prettier parts of country, so that for a tourist travelling through this country, at least to see the scenery, a vehicle would need to be sufficiently powerful to overtake a long grade of 1 in 9, with a pretty rough surface.

One of the circulars of an oil motor company states that it will ascend a grade of 1 in 10, but it seems to me this is scarcely sufficient, for Scotland at least, and I should be inclined to say that the English lake district, Devonshire, Derbyshire, Wales, and many parts of Ireland matters will be on a very similar footing. I venture to propose that in the trials some rough ascent of the grade I state should be incorporated as a supplement, with a view to satisfaction as to the universal utility of the better class vehicles. By doing so I think you would save annoying experiences to those unacquainted with exact steepness of the "dangerous" hills. HARRY R. G. INGLIS.

20, Bernard-terrace, Edinburgh, April 27th.

[We have no doubt that competitors will be fully prepared for the ascent of very steep hills. Whether it would be wise under any circumstances to attempt to work mountainous districts with horseless carriages is a question on which we express no opinion.—ED. E.]

SIR,—It is with great interest that your articles and paragraphs on the horseless carriage are read in Australia. For there is but little doubt that in a country where water is frequently very scarce, and horse feed occasionally dear, the demand for such vehicles must naturally grew apace. Though in Victoria as yet no one has ventured to import one of these machines, yet I would like to inform all English manufacturers that before they can with safety dispatch a carriage to this part of the world they must look to it that the motor can use an oil which is safe with the thermometer at 120 deg. in the shade. It frequently happens that that temperature is reached and occasionally exceeded, and if it approaches that in the shade the sun reading can be easily imagined. We have frequently had inquiries for these vehicles, but have not conscientiously been able to recommend them for the simple reason that we had doubts as to the safety of the oil used. If any maker of horseless carriages can provide a conveyance which will be unaffected by the most powerful sun's rays, and which will also be able to endure the rough usage which always falls to the lot of machinery that is handled by farm labourers, we shall be glad to be put into communication with them.

Melbourne, March 20th. PHILLIPS, ORMONDE AND CO.

THE NAVIGATION OF THE THAMES.

SIR,—The report to the Board of Trade by the Lower Thames Navigation Commission recalls attention to this matter. I have awaited its issue with great interest. The recommendations of the Commissioners are good, but I think it is to be regretted that the reference to the Commission was so limited, and did not include the Upper Thames—in fact, the whole river from the Nore to London.

It has long been a matter of surprise to me that the Thames Conservators should not have done more towards the deepening of the river. It is amazing that they should so lag behind the needs and demands of the time, and fail to provide for the requirements of the largest vessels, especially in view of what has been done by smaller ports and navigations. Why should London not be a "non-tidal" port right up to London Bridge? Would any spirited minor navigation allow such an obstruction to remain as the Thames Tunnel, with only 12ft. at low water? Probably the tunnel in time will have to go, and it seems to me that neither it nor the enormous values of riverside properties should be allowed to stand in the way of the provision of such a low-water channel as shall meet the needs of the largest vessels. The scheme of dredging proposed by the Conservancy Board will not do this. They should not hesitate to provide 30ft. from the sea to London Bridge.

A. SCOTT, Assoc. Mem. Inst. C.E.

Newcastle-on-Tyne, April 29th.

THE CRYSTAL PALACE.

SIR,—Will you kindly allow me a little space in your next issue to inform "M. E."—who writes to you from Dulwich, April 20th that the difference in level between the Low Level Station and the floor of the Crystal Palace is not "50ft.," but 157ft. If he will look on the 6in. Ordnance map of the district he will find the figures printed thereon. I venture to suggest that the best and, I believe, the cheapest method of conveying passengers from the Low Level Station into the Palace would be by means of a cable tramway simiiar to that now successfully in work between Kennington and Streatham Hill. I am sure no one would grudge the extra 1d. to be landed in the Palace, instead of having to tramp up the flights of stairs and along the almost interminable rising corridors, which is the only method in use at present. MEM. INST. C.E.

Westminster, S.W., April 27th.

TUBE WELLS AT GAINSBOROUGH.

SIR,—We notice in your issue of the 24th inst. a paragraph in reference to the boring at Gainsborough for the Urban District Council. The weight of tubes is mis-stated; it should be 28 tons instead of 18 tons. The boring, when plumbed at 310ft., was found to be 2¼in. out of perpendicular, 6in. having been allowed in the specification.

We are now about completing the borehole for the Goole District Council, which is 1000ft. deep, 18in. diameter, and are lowering in one complete length 835ft. of 15½in. perforated tubes weighing 18 tons. (For EBENEZER TIMMINS AND SONS, Ltd.),

Runcorn, April 27th. A. TIMMINS, Director.

RE ELECTRICAL COLONISATION.

SIR,—The scheme proposed by Mr. Meacock, of electrical colonisation, is not novel; it is almost identical with that formulated by Earl Russell and B. H. Thwaite, in the *National Review* some three years ago.

The proposal for rural districts is really very admirable, and would enable electric lighting to be cheaply obtained.

April 28th. RURAL.

AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

Concrete and iron arch bridge.—A highway bridge having two spans of 97½ft., two of 110ft., and one of 125ft., is to be built across the Kansas River at Topeka, and is to be on the Melan concrete and and iron system. It will have a 27ft. roadway, and two side walks 7ft. wide. The four piers and two abutments will be of monolithic concrete, one part Portland cement, three parts sand, and six parts 2½in. broken stone. Towards the surface this is to be one cement, two sand, and four parts ½in. stone, while the surface is to be faced with 1in. of one cement to two sand. There are to be twelve steel arch ribs, 3ft. centre to centre, each rib being a lattice girder 18in. deep over the angle iron chords—or booms—these ribs being connected longitudinally at the piers. There is no lateral metallic bracing. The concreting will be carried on in longitudinal ribs between the steel ribs, and this arch concrete will be composed of one part Portland cement, two parts sand, and four parts of ½in. to 1in. broken stone. The exposed faces and soffits will be faced with 1in. of mortar composed of one part cement to two of sand, thoroughly bonded to the main body of the concrete. Between the spandril walls will be earth filling, rammed hard, covered with a concrete pavement foundation of one part natural cement, two parts sand, and three parts broken stone. On this will be a 2in. cushion bed of sand, and one layer of paving brick set on edge. Expansion joints—filled with pine strips—are provided in the concrete walk. The side walk paving is of one part cement, two sand, and four stone, covered with 1in. of mortar, of two cement to one sand. The ribs are to be of open-hearth steel, with not more than 0·08 per cent. phosphorus, having an ultimate strength of 60,000 lb. to 68,000 lb., an elastic limit of not less than half the ultimate strength, an elongation of 28 per cent. in 8in., and a reduction in area of 40 per cent.

A 16in. gun lathe.—An immense lathe for boring and turning 16in. guns has been built by the Pond Tool Company, to the designs of the engineers of the United States Ordnance Department, and is to be erected at the Watervliet Arsenal. This great tool is 138ft. long over all, and its total weight is 280 tons. The carriages weigh 18 tons each, and the headstock weighs 52 tons. The 16in. rifled guns for which it is designed are about 50ft. long, and weigh 142 tons. The bed of the lathe is in six sections, each weighing 20 tons, and the sections carrying the boring bar are narrower than those carrying the carriages, rests, and headstocks. The main spindle of the headstock is of cast iron, 24in. diameter, with a bearing 31⅞in. long in an adjustable split cast iron shell. To the spindle is bolted the cast iron face plate, 18ft. diameter, weighing 13 tons, and to this is bolted the cast steel ring gear, 10½in. face, 8ft. 9in. outside diameter, the teeth being machine-cut, as in all the gearing of the lathe. The cone pulley has five steps for a 10in. belt, and by means of two sets of gearing and two speeds of countershaft, the spindle can be given twenty different speeds, ranging from 0·22 to nine revolutions per minute. The head screw is 5⅞in. diameter, 63ft. long, with a left-hand thread of four threads to 5in. The feed motion for the boring bar is transmitted from the head gearing to the foot of the lathe by a 4½in. steel shaft 137ft. long, made in two sections for convenience of transportation, and carried on drop bearings within the bed. The boring bar is of forged gun steel, 11in. diameter, 61ft. 3½in. long, and weighs six tons; it has a 4in. hole through it. The feeds for the boring bar range from 0·008in. to 0·17in. per revolution of the gun, while the clutch pulleys give it a motion of 28ft. per minute, independent of the motion of the gear. The gun is carried by two ring rests and a bent rest, forged steel rollers being placed in the sides of the rests. This lathe cost about £10,000.

Boring out heavy guns.—The 12in. steel breech-loading rifles, which are the largest guns as yet made at the Watervliet Arsenal, comprise eleven parts, all of forged steel, having an ultimate strength of 95,000 lb., and an elastic limit of 45,000 lb. The tube and jacket, 32,000 lb. each, are the heaviest parts, and the trunnion hoop, 5000 lb., is the lightest. The aggregate weight of the parts is 137,000 lb., while the finished gun weighs 116,500 lb., so that 15 per cent. of the rough weight, or 20,500 lb., is removed during the construction of the gun. The new 16in. guns will weigh 284,480 lb. finished. The ingots are usually forged hollow on mandrils, having previously been bored out in a lathe, and after being forged by steam hammers and hydraulic presses, the parts are annealed and oil-tempered. The tube is straightened on the lathe bearings, and counterbored to 11½in. diameter, for 6in. inside, this counterbore serving as a guide for the first boring tool. This is a "hog-nose" bit, of self-hardening steel, keyed upon a cast iron boring head. It cuts almost entirely forward, only a small portion of the cutting edge being carried around the corner to the side, this facilitating the boring of a straight hole. The cutting speed is 6ft. per minute, and the tool advances 0·04in. for each revolution of the tube. Work has been done at 9ft. per minute, with a feed of 0·08in. per revolution, but this is too rapid for good work. Lard oil is used for lubricating the cutter, and is carried off by flexible metallic tubing. For withdrawing the boring bar to inspect the cutter, a traverse motion of 15ft. per minute is provided. After this boring is made a second cut is taken with a wood rammer, consisting of a maple wood head—soaked in oil—carrying two cutters which cut only on the side. The cutting speed is 6ft. per minute, and the feed is 0·1in. per revolution of the tube. The jackets are bored in practically the same way.

River steamer.—A new steamer, the Adirondack, is to be put in service by the People's Line this summer on the Hudson River, and will run between New York and Albany, 140 miles, making the trip in about eight hours. The hull is 400ft. long over all, 378ft. long on the water-line, 50ft. beam, and has a loaded draught of 8½ft. The deck width over the guards will be about 75ft. The superstructure will carry four decks, each having a 10ft. promenade outside the state rooms, while the upper deck will form a wide space, covered by awnings and obstructed only by the pilot house, officers' quarters, and machinery space. There will be 328 state rooms, smoking room, main and ladies' saloons, a large dining room on the main deck, and all the conveniences provided on these steamers in the way of toilet rooms, news-stands, bar, barber's shop, &c. The hold will have a capacity for 1500 tons of freight. The interior will be finished in white and gold, and handsomely carpeted, upholstered, and furnished. The electric light plant will include 2000 incandescent lamps and a powerful search-light. The engine is of the old-fashioned vertical type, with walking beam above the upper deck. It is a single-cylinder surface condensing engine, with cylinder 7ft. diameter and 12ft. stroke, developing 4000-horse power, and designed to give a speed of eighteen miles per hour. Steam will be supplied by four double-end marine boilers, 11ft. diameter and 33ft. long, carrying about 150 lb. steam pressure. The walking beam's connecting-rod drives direct the main crank shaft. The side wheels or paddles are 30ft. diameter and 12ft. wide, fitted with feathering buckets.

Sewage disposal.—This is a subject which is becoming of the utmost importance in a number of cities, towns, and suburban districts, and the various methods of effecting the disposal are attracting considerable popular, medical, and engineering attention. Boston probably affords the best example of main drainage for the disposal of sewage. Formerly there were about forty-three separate outlets directly into the harbour and near the ends of the docks, where there was little wave action. Now it is carried by means of interceptors into a main sewer, and after passing through a depositing main and an inverted syphon, is carried by means of an embankment to a storage reservoir on Moon Island. The storage reservoir on the island is so arranged as to discharge its contents in half-an-hour if necessary, although it usually takes about eleven hours for the reservoir to fill. About an hour and a-half after discharge, at a distance of two miles, no contamination is noticeable. This is one of the most successful exhibits of disposal by dilution to be found in this country. The sewage farm at Berlin, Ontario, is generally classified as an instance of broad irrigation, but as the field was constructed by excavating trenches about 17ft. apart, with tile drains and back filled with gravel, it acts rather as a filter for the sewage. The amount of sewage disposed of is about 15,000 gallons per acre per day. The field of eight acres cost 800 dols., and the cost of preparation was 3000 dols., making the total 3800 dols. The broad irrigation field at Pullman, Illinois, does not seem to be so great a success as has been claimed, and a reliable authority stated that upon the occasion of a visit he found that a 140 acre field for broad irrigation had not been used for three years, and was being otherwise fertilised, while a supplementary filtering area of fifteen acres had not been used for a month. The total sewage from the town of 10,000 inhabitants was being carried in an open ditch to Lake Calumet, and the plant seemed to be operated not to purify sewage but to make money. The soil at this place was not at all suitable for sewage filtration or for broad irrigation. In the experiments made at Lawrence with one filter that had been operated for two years under 86,000 gallons per acre per day, the purification was effected to the extent of removing 94 per cent. of the organic matter and 98 per cent. of the bacteria. Another filter run for the same length of time under 49,000 gallons removed 97 per cent. of the organic matter and 99 per cent. of the bacteria. In the chemical process the sludge which comes from the compressors is little valued as a fertiliser; the farmers will hardly take the trouble to cart it away. At Canton, Ohio, there is a plant for the chemical disposal of sewage. It is first treated to 8 grains of lime and $1\frac{6}{10}$ grains of sulphate of alumina per gallon. It is then passed into a channel, where it is agitated by boards sticking out at the sides, from there through a series of tanks, where most of the solid matter is precipitated, and flows out over a series of steps, by which it is aërated. The sludge is forced into a filter press at a pressure of 100 lb. per square inch, which reduces the precipitated matter to the sludge cake. The cost of this process is a little over 11 dols. per million gallons of sewage purified. At Long Branch, New Jersey, the sewage is treated chemically by alum and lime. In the plant erected at the Chicago Exhibition, the solids in the sewage from the grounds were chemically precipitated by the use of copperas and lime, and were then compressed and burnt in the garbage crematory. It seemed to be a complete success.

THE CIVIL AND MECHANICAL ENGINEERS' SOCIETY.—At the ordinary meeting held on April 23rd a paper was read before this society by Mr. W. Cooper Penn, A.M.I.M.E., on "Anchors." The author traced their development from the days of the Romans down to the present time, and gave particulars of interesting trials of various forms and patterns of anchors made by the Admiralty at various times. He also entered into the details of construction of many of the modern anchors, particular attention being drawn to the stockless anchors now so much in vogue. A discussion ensued, and a vote of thanks to the author of the paper terminated the meeting.

THE ELECTRIC LIGHTING QUESTION AT BATTERSEA.—The result of a competition for the best method of dealing with a public supply of electricity in Battersea has been announced. In September instructions to electrical engineers were prepared, and premiums of £50, £30, and £15 were offered for the best three schemes submitted, the schemes finally selected to become the property of the Vestry, and the premium of the successful competitor, in the event of his scheme being carried out, to merge into and form part of the commission or remuneration for the supply of detailed plans and specifications, and for general superintendence of the work. Each competitor was required to submit with his scheme a report as to the best method of utilising the waste heat from the destructor at the Vestry Dust Depôt, and to provide in his report for the following:—1. For lighting a small area. (*a*) The lighting of the main and side roads, and (*b*) the lighting of public and private property. 2. For extending the lighting (*a*) to all main roads, and (*b*) to public and private property abutting thereon. 3. For extending the lighting (*a*) to all side roads, and (*b*) to public and private property abutting thereon. Full sets of plans had to be submitted with each scheme, and detailed estimates given of the capital outlay involved and of the cost of working, showing what advantage would be likely to accrue by its adoption. The "instructions" were duly issued to twenty-eight applicants, and in response thereto twenty-one sets of schemes were submitted by December 12th. The Electric Lighting Committee appointed Mr. Robert Hammond, M.I.E.E., as expert to advise the committee and report on each of the schemes submitted. Mr. Hammond's report as to the relative merits of these schemes was fully considered by the committee, and in accordance with his recommendation, the premiums last week were allotted by the Vestry as under:—

Mark of scheme.	Amount of prize.	Name of winner.
1st.—J.	£50	The Brush Electrical Engineering Company, Ld.
2nd.—M.	£30	Mr. W. Best
3rd.—F.	£15	Mr. J. Hardie McLean.

The above-named schemes were referred back to the committee, who have instructions to prepare a scheme for dealing with the electric lighting of the parish and to submit same to the Vestry at an early date. The Vestry at their meeting also adopted the recommendation of the Electric Lighting Committee in respect to the lighting of the Town Hall by electricity, and have decided to put the work in hand at once. Mr. Hammond has been appointed as the consulting engineer to carry out the work, at a fee representing 5 per cent. upon the capital outlay. It is estimated that the cost of the scheme will be about £3000, for a loan for which application will be made to the London County Council. The generating works for the Town Hall lighting will be erected on the vacant land at the rear of the present buildings.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

PIG iron is quoted this week:—Cold blast, 90s.; Staffordshire all-mine, 55s.; part-mine, 40s. to 42s. 6d.; and cinder pig, 35s. 6d. to 36s. Northampton forge pig is 40s.; North Staffordshire and Derbyshire, 41s. to 42s.; and Lincolnshire, 42s.

In finished iron marked bars remain at £7, with the usual 12s. 6d. for Lord Dudley's L.W.R.O. make; merchant bars are £6 to £6 5s., and common bars are £5 5s. to £5 10s. The depression in the sheet trade, arising from over-production, continues. Black sheets are £6 10s. to £6 15s. for doubles, and £7 15s. lattens. Galvanised sheets are about £10 for 24-gauge at Liverpool. Stamping sheets are £9 10s., and best thin sheets £11. Angles are £5 15s.

There is a brisk demand for steel at £4 15s. to £5 for Siemens slabs, £4 10s. for Bessemer blooms and billets, £5 15s. to £6 for bars, £7 5s. to £7 10s. for sheets, and £5 12s. 6d. to £5 17s. 6d. for angles and boiler plates. Basic steel girders and angles are £5 10s., and boiler plates £6 5s.

Large quantities of steel are now being used by the weldless steel tube makers who supply the cycle manufacturers, and there is every reason to believe that the demand for this material will continue to grow, since the cycle tube industry in South Staffordshire is rapidly extending, and promises in time to become as important locally as it is in Birmingham. There is no lack of capital for new steel tube undertakings, and several new companies which have recently been put forward have had their capital considerably over-subscribed. The growing scope of this particular class of market for steel is further indicated by the circumstance that the cycle engineering trade itself is at the present time experiencing a perfect "boom," and orders have had to be refused in this district to an extent unparalleled in any previous year. A good deal of Swedish steel has up to now been used for drawing weldless steel tubes for cycle frames, for which purpose the material has, of course, to be of extra quality, but although the purchases of Swedish steel still continue large, yet steel tube makers are finding, much to their satisfaction, that they can now get supplies of sufficiently good material near at home.

The Executive Council of the County Councils Association recently invited an expression of opinion by county councils upon two points, viz.:—(*a*) As to the desirability of imposing a tax upon cycles, the proceeds of which should be paid to the county authority in aid of the highway rate; and (*b*) as to the expediency of numbering and registering annually all cycles, in order to render identification more easy, and of charging a licensing fee sufficient to cover the expenses of such registration. Replies have been received from twenty-four counties. Four only are in favour of taxation. Fourteen counties, including Staffordshire, are opposed to taxation, and six counties, including Warwickshire, are not prepared to express an opinion. Six counties are unreservedly in favour of registration, and five are unreservedly opposed to it. Lancashire is prepared to consider a scheme of registration when devised; Somerset and Surrey think registration desirable, but practically impossible; while Staffordshire and Warwickshire are in favour of representing to the Home Secretary the need of conferring on police authorities the means of identifying cyclists who have broken the law. Before, however, either taxing or registration of cycles are carried into effect, not only the counties but the towns will have something to say on the matter; and Wolverhampton, Coventry, and Birmingham, in which towns the manufacture of cycles is a very important industry, will certainly strenuously oppose any action tending to hamper the freedom of their customers, and to thus retard the popularity of cycling.

At a meeting of the Council of the Walsall Chamber of Commerce on Monday, the president, Mr. E. J. Shaw, adverted to the Select Committee on Lamps, and, as showing the importance of the lamp trade in that particular locality, said there were from 10,000 to 15,000 persons engaged directly or indirectly in the Midlands in the manufacture of lamps. The Committee were having witnesses from different parts of the kingdom in reference to the storage of petroleum oils and the making of lamps; but those who had been called so far were mainly professional gentlemen not closely identified with the manufacture of lamps, and to much of the evidence given lamp manufacturers were taking strong exception. The evidence was unreliable in a great measure, and it afforded an instance how large an industry might be injuriously affected by a wrong kind of evidence being laid before the Committee, and a Bill being drafted on the recommendations of the Committee. He suggested that a representative of the Chamber should be sent to give evidence before the Committee. Mr. T. A. Hill proposed that the president be asked to attend, and the motion was seconded by Mr. T. A. Smith, and unanimously agreed to.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The possibility of another conflict between the federated coalowners and miners, to which I referred in my notes last week, is necessarily causing increasing concern, but scarcely any really serious apprehension as to the probability of a protracted stoppage. The attitude taken up by the miners at their conference this week has been very much what I indicated in my previous notes; they seem to be thoroughly determined on the question of establishing a minimum wage, and the issue will, in all probability, turn upon whether, by some mutual concession, a satisfactory arrangement can be come to which will enable the Conciliation Board to be renewed. So far as the coalowners are concerned, I know for a fact that several of the principal leaders in the last conflict with the men are thoroughly determined not again to be made what they term the "cat's paw" for other collieries, who early broke away from the combination, and reaped a very substantial advantage from the high prices, at the expense of the colliery concerns who remained firm, and in any case there is certainly no probability of another such strong combination of coalowners to carry on a protracted struggle with the Miners' Federation. On the other hand, the Miners' Federation is not in any strong financial position, and during the period of depressed trade for the last two years has suffered considerable loss in membership, so that neither side will be in a position to fight out anything like a general or protracted conflict, and this will no doubt considerably favour the disposition for compromise. The absence of any serious apprehension of renewed strife is evidenced by the continued inactive condition of the demand for nearly all descriptions of fuel; so far there has been no pressure whatever to get in extra supplies in anticipation of a possible stoppage of the pits, nor has there been even any special anxiety with regard to forward contracts, which would certainly be the case if there were any real fears of another long suspension of work at the collieries.

If anything a rather more active inquiry was reported on Tuesday's Manchester Iron Exchange, and here and there a moderate business was being put through. Generally, however, the tone of the market continues dull, and there has been some further easing down in makers' prices for pig iron, whilst on the other hand low sellers of iron held in second hands have, in some cases, been slightly hardening up in their quotations. With regard to district brands, moderate orders have been booked by Lincolnshire makers at the reduced rates, chiefly in forge qualities for shipment, and prices are very firm on the basis of 41s. for forge to 43s. for foundry, net cash, delivered Manchester; Derbyshire iron, which has recently been showing a lack of firmness, has, following the reduction in Lincolnshire, given way to the extent of about 6d. per ton, 46s. to 46s. 6d. net cash being now the full average figures for foundry qualities delivered here. Lancashire pig iron makers, who are well booked for the present, are fully maintaining late quotations, No. 3 foundry remaining firm at 46s. 6d., less 2½, delivered Manchester. In outside brands offering here prices continue irregular; makers would now, in some cases take 46s. 10d. net cash for good foundry Middlesbrough, delivered by rail Manchester, whilst as regards iron in second hands there is a slight stiffening tendency, 44s. 9d. being quoted for delivered at the Manchester docks. Scotch iron offering through second hands also shows rather more firmness, Eglinton being quoted 46s. 9d. to 47s., delivered Lancashire ports, and 49s. 3d. delivered Dock Quays, Manchester, with Glengarnock at 48s. at the ports and 50s. 3d. delivered Dock Quays, Manchester.

In the manufactured iron trade a fair weight of business continues to be reported, and prices for bars are firm at recent quotations, local makers not taking anything under £5 10s., but shipping orders have been booked at 2s. 6d. below this figure. North Staffordshire bars are without change, £5 12s. 6d. to £5 15s. being the average figures for delivery here. As regards sheets, a weak tone prevails, and orders could now be placed at still lower prices, £6 17s. 6d. to £7 being about the average for singles, delivered in this district. For hoops the Association list rates remain without quotable change, and are firm at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths, delivered Manchester district, with 2s. 6d. less for shipment.

A moderate demand comes forward in the steel trade, and a steady tone is maintained as regards prices, makers showing no disposition to give way upon late quotations, although there are low sellers amongst merchants. Good foundry hematites are still quoted by makers 58s., less 2½, but merchants would take about 57s. For steel billets, £4 7s. 6d. net cash represents about the average figure, with local steel bars quoted £6, and boiler plates obtainable at from £6 5s. to £6 7s. 6d. per ton, delivered in this district.

In the metal market the demand generally continues brisk, and prices are exceedingly firm at the full list rates, attempts being made, in some cases, to secure some advance upon these on small sales.

The position throughout the engineering trades continues generally satisfactory, establishments being mostly kept full going upon work in hand, with new orders in most branches coming forward freely, and there is every prospect of steadily increasing activity through the remainder of the year.

The other day I was shown a new design in pumps, Mose's patent, which is being introduced by the Patents Company, 35, Market-street, Manchester. This pump can be used either as an ordinary or as a force pump, according to requirements, the alteration from the one to the other being effected by simply moving an india-rubber ball—which, under ordinary conditions, rests at the end of the discharge pipe—over the orifice of the pump, when the water will be forced to flow through a contracted pipe outlet at the top, to which a hose length can be connected, and the water is discharged in a strong jet. Another special feature of this pump is the introduction of an internal lining of non-freezing material, which renders the pump impervious to frost during the winter months. The pump is also made with an inside brass liner, with a special bucket, designed to reduce the wear and tear.

Messrs. Leech Brothers and Co., of Old Millgate, Manchester, have brought out an improved form of radiator, suitable for large or small buildings, which can be heated either by steam or hot water. The radiator consists of a series of loops, ranging from three to any number up to a hundred, as required, which are connected by face joints, and amongst the advantages claimed for the arrangement are the exceptionally large heating surface presented, in proportion to the height of the loops, which ranges from 30in. to 36in., whilst it is impossible for any steam or hot water to escape from the radiator, and no india-rubber packing is used for making the joints.

In the coal trade the condition remains without material change. The demand all through, except for engine fuel, is extremely slow, and pits continue on not more than four days per week. For the best qualities of round coal, suitable for house fire consumption, requirements are of necessity slackening off with the advance of summer, and although quoted rates are unchanged, prices show a weakening tendency, buyers who could place orders for anything like quantities being able to obtain concessions. The lower qualities of round coal continue difficult of sale, and prices are so excessively low that many of the collieries are either ceasing to work their common mines, or lessening their output as much as possible by putting them on short time. Perhaps no more conclusive evidence of the unsatisfactory outlook in this branch of the coal trade could be afforded than the low prices at which the important railway contracts for forge coals are being renewed. Last year they were taken at what was considered the low figure of 6s. 3d. per ton; this year 5s. 9d., or a reduction of 6d. per ton upon last season's contracts, is being taken, one colliery having placed about 50,000 tons at that price. I hear that even this is considered to be a good figure compared with the prices which some of the collieries have been taking for the same class of coal for shipment, and that it would not have been difficult to place contracts at 5s. 6d. per ton. The ordinary pit mouth prices for steam and forge coals for inland sale still average about 6s. per ton. Engine classes of fuel move off readily, and with supplies not over-plentiful, prices show a hardening tendency, slight advances of about 3d. per ton being obtainable in some instances, but generally quoted rates, although very firm, are unchanged, 3s. 6d. to 3s. 9d. being about the average figures for common slack, with best sorts ranging from 4s. 6d. to 5s. at the pit mouth.

No improvement is noticeable in the shipping trade, and common steam coals can still be readily bought at 6s. 9d. to 7s., delivered ports on Mersey or Partington tips, Manchester Ship Canal.

Barrow.—The business doing in hematite qualities of pig iron is steady and brisk, and makers find that they have plenty of orders to engage their attention for some time. Indeed, generally speaking, they are booked forward for fully six months ahead, while those smelters who have also steel works can book ahead for fully a twelvemonth. Prices are firmer on the week and although makers have not changed from their quotation of 50s. per ton for mixed Bessemer Nos. net f.o.b., warrant holders are asking more money. Sellers are at 48s. 1½d. per ton net cash, and buyers at 48s. 1d. Stocks have not been increased or decreased during the week. They still represent slightly over 300,000 tons.

Iron ore is in considerable demand on native as well as on Spanish account. Spanish, indeed, are being more largely imported, as their use in the blast furnaces with native ores has been found to be a distinct advantage. Average qualities of iron ore are quoted at 10s. per ton net at mines, and best descriptions find a good market at from 12s. 6d. to 14s. 6d. per ton. Spanish descriptions are still quoted at about 13s. per ton for 60 per cent. qualities delivered at West Coast ports. There are from three to six steamers in Barry docks every week with cargoes of ore for the various smelters in the district.

Steel makers report an active condition of things all round. The rail trade is very busy. Orders for heavy sections are plentiful, and are already well held. Home, colonial, and foreign buyers generally are in the market. Heavy sections are firm at £4 15s. per ton net, f.o.b. The demand for all classes of shipbuilding material is well maintained, and the plate mills are busy, and likely to remain so. Ship plates are still firm at £5 2s. 6d. per ton net. There is still a good trade in billets and hoops, and merchant qualities of steel generally are in good demand. Tin bars are quiet, but some good orders for steel sleepers have fallen to the lot of West Cumberland steel makers for the Colonial Governments.

Shipbuilders and marine engineers are getting short of orders. The works at Barrow are so large that they require a big tonnage of work to keep them briskly employed. Much new work has recently been tendered for on commercial account, and there is also some large Admiralty work to give out during the year, but in the meantime builders and engineers are short of work to go on with, although a large amount of Admiralty work is at present receiving attention.

The coal and coke trades are brisk, but there is no alteration to note in prices, coal, indeed, being weak, while coke is strong in values.

The shipping trade is slightly depressed this week, especially in regard to shipments of pig iron, which show a falling off.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

GENERALLY the iron market has this week been more favourable to sellers than for some time past, and business certainly shows a distinct improvement upon last week, the demand being brisker, and higher prices are realised. This is rather contrary to the experience, for when near the end of the month in the pig iron market prices become easier, as there are usually cheap lots offering by speculators who have iron over, and these forced sales weaken the market. However, there does not in April appear to have been much of this, the speculators having generally oversold accounts, and they have had to buy to cover. Advantage of this has been taken by the sellers, who have advanced their prices at least 3d. per ton all round for pig iron, and some even more. This has brought into the market a considerable number of buyers who were hesitating to purchase, and there seems to be more disposition to do business. Last week 37s. 9d. per ton was the figure for early deliveries of No. 3 Cleveland G.M.B. pig iron, but early this week 37s. 10½d. was readily paid for deliveries to be made before the end of the week, and 38s. has been the regular figure for May deliveries, both makers and merchants holding out for and realising this, while the leading firms would not let their iron go under 38s. 3d., as they are of opinion that a continued active trade will be done.

Cleveland warrants, which on Tuesday last week were down to 37s. 8d. cash, the lowest figure which has been known since the middle of January, have taken a turn upwards, and this week they have been as high as 38s. 4½d., but on Wednesday there was business at 38s. 2d. cash. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 193,357 tons, an increase of 5883 tons for the month, this having chiefly accumulated during the past week, for little iron was sent in during the first fortnight. Nevertheless, it is expected that the aggregate stock of Cleveland pig iron in the district will for April show a decrease of about 3000 tons, and that will be the first time since October last that the consumption has exceeded the production. The price of No. 4 Cleveland pig iron is firm at 37s. 6d. and grey forge 37s. for early delivery. Cleveland hematite pig iron hardly holds its own so well as Cleveland ordinary iron, as it is thought that the output is too large, though that is a question which cannot readily be answered, for, while the extent of the production is made known, no particulars are given of the stocks. The general belief, however, is that more hematite pig iron is made than is required, and so consumers are backward about buying anything more than satisfies current needs. Shipments of hematite pig during April have shown considerable improvement. Mixed numbers are quoted 46s. 3d. for May deliveries, and this is paid by consumers who would not pay more than 46s. 3d. early in the week.

Exports of pig iron from the Cleveland district during April have been very good, up to Wednesday evening they reached 98,561 tons, against 89,147 tons in March and 106,929 tons in April, 1895. The exports for April have been much above the average of that month in recent years, that average being 85,000 tons. The year's shipments so far have been greatly in advance of those of any previous year.

Messrs. Bolckow, Vaughan and Co., at their pig iron works in the Eston district are spending a large amount of money in improving the plant; they are erecting new kilns, laying down new boilers, and having new blowing engines constructed. At the Southbank fourteen calcining kilns are being renewed, and are being so arranged as to save a good deal in labour. At the Cleveland Works eleven old boilers are to be replaced by Lancashire boilers. These old boilers are of the long cylindrical egg-ended and externally-fired type, which was so strongly condemned by the Board of Trade Commissioners when last July they inquired into the disastrous boiler explosion at the Redcar Ironworks, by which twelve lives were lost. Since this decision, almost all who had these boilers have been altering them or putting in new boilers. Messrs. Bolckow, Vaughan and Co. have already replaced twelve of such boilers by eight Lancashire boilers. The firm have for some time been of opinion that they were not getting out of their Cleveland furnaces as large a quantity of iron as they were capable of producing, in consequence of the lack of blowing power. They have, therefore, decided to erect new and independent blowing engines for their hematite furnaces there, and new engines, engine house, and boilers will be erected, £15,000 being applied out of revenue in part payment for the new blowing plant. All the alterations are to be paid for out of revenue, none being charged to capital.

Shipyards generally are actively employed, and the improvement has been so marked that the yard of Messrs. Osborne, Graham and Co., at North Hylton, on the Wear, has been reopened after a stoppage for a considerable period. The British Admiralty have furnished a large amount of work in the yards of this district by their orders for torpedo boat destroyers and cruisers, these orders all going to the Tyne and Wear. The yards on the Tyne receiving such contracts were enumerated last week but it also appears that Messrs. Doxford and Sons, of Pallion, on the Wear, have secured the contracts for two torpedo boat destroyers similar to those which they constructed last year for the British Government. The demand for merchant steamers is good, and builders have no difficulty in filling up the berths of the vessels they launch.

At a meeting of the North-East Coast Institution of Engineers and Shipbuilders, held at West Hartlepool on Saturday, the chairman—Mr. Robert Thompson, of Sunderland—when speaking of the question of foreign competition in shipbuilding, in the course of a discussion, made the remark that British shipbuilders had got this "beastly climate of ours" to thank for a good deal, yet much as it was complained of, there was not a country on the Continent where the men could work so many days per year as they could in England.

When the Redcar Ironworks boiler explosion occurred last June, Messrs. Walker, Maynard, and Co., the owners, were insured in an Employers' Liability and Accident Insurance Company against claims under the Employers' Liability Act. It being decided by the Board of Trade Commissioners that the explosion occurred through the negligence of their servant, the firm were liable to pay compensation to those who suffered by the accident, and they have since agreed with the representatives of the men as to the legal compensation to be paid. They have paid this over, and now require the Insurance Company to refund the money to them. As to their liability after the decision of the Commissioners, the Insurance Company are at any rate doubtful, and the whole question is be submitted to arbitration.

The Board of Trade Commissioners have this week held inquiries at Newcastle into two boiler explosions. As to the first of these—the explosion of a boiler at the Barrington Brickworks, belonging to the Bedlington Coal Company—they gave an important decision as to the testing and supervision of boilers. They held that the Bedlington Coal Company was responsible because its inspector had not applied the hydraulic test to the boiler after certain repairs, and they blamed the Scottish Boiler Insurance Company also, because its agent had not properly examined the boiler, especially in December, 1895. A proper test, they held, would in all probability have discovered the seam rip, and prevented the explosion. The Bedlington Coal Company was also to blame for omission to inform the insurance company of the repairs to the boiler. The two companies were, therefore, each ordered to pay £40 towards the cost of the inquiry. The counsel for the insurance company entered his protest against the decision, which he said would revolutionise boiler insurance and inspection throughout the kingdom. The boiler was a very old one, was 30ft. long by 6ft. diameter, and was constructed of iron. It was of the cylindrical egg-ended type, externally fired. The explosion occurred on March 12th, and the engineman lost his life.

Ironfounders are more actively employed on the whole, as are also the bridge builders and engineers. Part of the cast iron segments that are required in the construction of the City of London subway are to be furnished by Messrs. Head, Wrightson, and Co., Teesdale Ironworks, Thornaby-on-Tees; part by Messrs. Smith, Patterson, and Co., of Blayden-on-Tyne; and part by Scotch founders. Messrs. John Abbot and Co., of the Park Works, Gateshead, are to supply the steel roofing girders for the electricity station of the Harrogate Corporation. A rumour is in circulation that a new engineering company is to be established on Tees-side, but no particulars are yet available.

In the finished iron and steel trade no change can be reported, works are well employed, and orders booked are numerous, but new orders are scarce. Prices are unaltered.

In the Northumberland steam coal trade there is now considerable activity, as was looked for as soon as the navigation season was fully open, and large shipments are being made to the Baltic. Good exports are also reported to South America. The improvement has led to a rise of about 6d. per ton in the prices recently. In the early part of the month 7s. 9d. per ton f.o.b. was all that would be paid for best steam coals, now 8s. 3d. is being quoted and paid, and steam smalls were from 3s. 6d. to 4s. Heavy shipments have been made this week to Cronstadt, navigation to which has only just been opened. The home consumption of gas coal is quieter, but there is a fair export. The wages of Northumberland colliery enginemen have been reduced 2d. per day, and of firemen 3 per cent., deputies also being reduced to a like extent. Coke is firm at from 13s. 6d. to 14s. delivered at furnaces on Tees-side, or 15s. f.o.b.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

IN the Yorkshire colliery districts stocks continue to be large, and the most discouraging feature is that they are still growing. In some directions an improving tendency is reported, but taking the fuel industry all round there is really no change to report on the week. Steam coal is now getting into more active demand, both Hull and Grimsby having larger supplies sent from the local collieries, the former being still the favourite port to which the collieries with the largest output send their produce. Although prices are still low they are pretty steady, Barnsley hards are quoted at from 6s. 6d. to 7s. per ton; secondary qualities from 6s. per ton. Household fuel, as might have been expected in consequence of the continued mild weather, gets weaker every day. The tonnage going from the district is about the smallest that has been known for years, and the rule is the smaller the tonnage the keener the competition. What trade there is in the metropolitan market mainly falls to the coal sent from the North by water. This enables agents to exact fresh concessions from inland coalowners, and those of their number who cannot hold their stocks are obliged to offer special terms to effect a clearance. The easier rates which have ruled during the present month are still inadequate to let inland pit owners compete successfully with Northumberland and Durham fuel. The best demand is for the higher qualities of Silkstone, which make from 8s. to 8s. 9d. per ton; ordinary from 6s. 9d. per ton. Barnsley house ranges from 7s. 3d. to 8s. 3d per ton; other qualities, from 6s. 6d. to 7s. 3d. and 7s. 6d. per ton. There is again a falling off in the request for gas coal, which does not make more than from 6s. to 7s. per ton, with falling values. A continued improvement in trade is favourably affecting manufacturing fuel, and a slight upward tendency is noticed in the lower-priced sorts, which have long been at a most absurdly low price. On the other hand, nuts of good quality are bad to sell even with declining prices, which almost counterbalances a better demand for small stuff, caused by the revival in the coke business with Lincolnshire, Northamptonshire, and the West. Small nuts may be quoted at 4s. 3d. to 5s. 3d.; screened slack, from 3s. 3d.; pit slack, from 2s. 6d.; smudge, from 1s. to 1s. 6d. per ton. Coke is in good demand at from 8s. 6d. to 10s. per ton.

In nearly all the departments of the heavy industries trade is satisfactory. Some foreign orders are now coming in for war goods, which added to the heavy requirements of the Government, promise good work during the year. The armour plates required under the new Admiralty scheme are being rapidly pushed forward. There never has been a time when the large armour plate rolling and planing mills and shops have presented a more active scene of industry than at this moment. It is expected that some further good work will soon be booked on foreign account. Railway and marine material continues to be freely placed, and the local firms who have specialities in Atlantic-going steamers are exceedingly busy.

In the lighter industries the reports are considerably varied. In some firms complaint is heard that the business is more of a parcel post description than they like. Merchants at a distance order goods as they require, and the speed with which they can now, thanks to postal facilities, get their orders fulfilled militates against accumulations of work, which enable employers to guarantee their men any length of engagement. It is particularly disappointing to know that the principal cutlery houses, whose chief market is America, describe business as altogether unsatisfactory. The revival which began at the end of last year, and from which so much was expected, seems quite to have passed away, leaving trade as depressed as at any period of United States stagnation. This is all the more unsatisfactory, as the American houses ought now to be in the full swing of the spring season and exceptionally busy. On the other hand, the improvement in the Australian trade, to which attention has already been directed in THE ENGINEER, is a most gratifying feature. Good orders for cutlery, tools, and general hardware, have been received during the last month by the leading Sheffield houses, whose representatives travelling throughout Australia sent home most encouraging accounts. Australia has evidently been rapidly recovering from recent embarrassments, as travellers have little difficulty in collecting what is due, and find merchants more disposed to place work. There is also a better state of things prevailing in the Brazilian and general South American markets, although the competition of United States and continental agents is increasingly severe.

India, China, Japan, and Mexico are all yielding better work, although the orders placed are not so heavy as could be desired. The Government contracts for ivory-handled table cutlery, which comprises from 1000 to 1200 dozens, will soon be placed. It does not excite much enthusiasm, as all the Government work is "cut" very low, and the conditions of acceptance are so onerous that there is not much to be had out of it. But Government orders are regarded from different points from ordinary work. They are useful as advertisements with foreign countries; they are in large quantities, keep the men employed betwixt seasons, and the deliveries are at periods from three to twelve months. The depression in the cutlery branches will seriously affect ivory cutters if it is continued. The London ivory sales now proceeding are expected to result in high values, owing to the smaller weight and the increasing demands for other purposes.

The pearl cutters report that their business has drooped, particularly in the higher grades. German cutlery manufacturers, a year ago, competed keenly for the better classes of pearl handles, but this year they are confining their requirements to the commoner goods—a feature which confirms the popular impression that the Germans, like the Americans, are most successful when they devote themselves to a vast output in the lower grade goods at a very lean price.

The decision come to by the Miners' Federation of Great Britain at Nottingham has excited no surprise here. It was known in this district that the miners' ballot was precisely as the miners' leaders wanted. It declares firmly for "the living wage," that is, for a minimum rate, below which wages shall not fall. That minimum they find in the present amount, which is 30 per cent. above the standard of 1887. In return, they are willing to concede to the masters a maximum wage, which they fix at 45 per cent. above the 1887 rates. The employers are not willing to have the Conciliation Board continued on these terms. They prefer that the Conciliation Board should have power to determine the rate of wages from time to time as the state of trade demands. That conceded, the coalowners would be glad to have the Board continued for an indefinite term. The miners' leaders specifically state the period of continuance as two years. A compromise has been suggested, with the minimum wages fixed at 20 per cent. instead of 30 per cent., and the maximum left at 45 per cent. The miners' leaders point out that this practically means a reduction of 10 per cent. in wages, and they do not see their way to consent to that. Mr. A. M. Chambers, President of the Coalowners' Federation, speaking at Thorncliffe on Tuesday, declared that "times were difficult, and the issues at stake very great. All they could do was to hold their hands, to keep their powder dry, and try to bear the ills they had, rather than fly to others, some of which they knew a great deal too much about."

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE was a marked improvement in the pig iron warrant market in the early part of the week. Scotch pig iron, which was down last week as low as 45s. 11d. per ton, advanced to 46s. 9½d. cash, and 46s. 11½d. one month; a very considerable business having been done. For Cleveland warrants there has been little inquiry, the cash price being about 38s. 4d. A moderate business was done in Cumberland hematite warrants at 48s. 2d. to 48s. 5d. cash, and 48s. 5d. to 48s. 7d. one month. The rise in prices was in some measure sympathetic, the tone of the market being favourably influenced by an improvement in the prices of stocks and shares. At the same time the business in pig iron between sellers and consumers outside of the speculation market is large, probably as great as it has ever been at any former time, the great bulk of the iron going into use at home.

Stocks of pig iron in Glasgow warrant stores show little variation. No additions are being made; indeed, in the past week, a slight decrease was noted in the stock. Connal's stores now contain 283,675 tons, which shows an increase since the beginning of the year of 10,000 tons. Taking into account the amount of the production, which is somewhere about 28,000 tons per week, this addition to stock will be sure to be of comparatively small importance. There are at present 43 furnaces producing ordinary, 35 hematite, and three basic pigs, the total of 81 comparing with 75 at this time last year. A large demand exists for hematite pig iron. It is understood that the whole of the output of the 35 Scotch furnaces is going into consumption, besides large quantities of Cumberland and Middlesbrough hematite.

The prices of Scotch makers' pig iron are as follows:—Govan and Monkland, f.o.b. at Glasgow, Nos. 1, 47s. 6d.; Nos. 3, 46s. 3d.; Wishaw and Carnbroe, Nos. 1, 47s. 9d.; Nos. 3, 46s. 6d.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1, 50s. 6d.; No. 3, 48s.; Calder and Summerlee, Nos. 1, 51s.; Nos. 3, 48s.; Coltness, No. 1, 53s. 6d.; No. 3, 49s.; Glengarnock, at Ardrossan, No. 1, 51s.; No. 3, 47s.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington, at Ayr, No. 1, 47s.; No. 3, 45s.; Carron, at Grangemouth, No. 1, 52s.; No. 3, 48s. 6d.; Shotts, at Leith, No. 1, 53s.; Nos. 3, 49s.

The shipments of pig iron from Scottish ports in the past week have been 7203 tons, compared with 5427 in the corresponding week of last year. The foreign demand is still unsatisfactory.

In the finished iron and steel branches there is no change of importance. The activity already noted in these departments is fully maintained. Prices of both iron and steel are steady and it is not easy to obtain any advance on prices. A very animated business is being done in sheets, the makers of which are working day and night. Tube makers are likewise very busy. Locomotive and marine engineers and the producers of bridge and railway materials report brisk trade.

The only department of the coal trade that is at all active is that for the supply of manufacturing fuel. The various kinds of furnace coal, including nuts and dross, are in good request at firm prices. Steam coals are difficult to sell; and splint, being in very full supply, is easy. The prices f.o.b. at Glasgow are, for main coal, 5s. 9d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; and steam, 7d. 6d. per ton. The shipments of coal from the various Scottish ports in the past week aggregated 152,227 tons, compared with 142,345 tons in the preceding week, and 151,004 tons in the same week of 1895. The total coal shipments since the beginning of the year amount to 2,041,993 tons, being 137,255 tons more than in the corresponding period of last year.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

LAST week Cardiff shipped 340,000 tons of coal—50,000 tons above the average There is not much change in the situation of the coal trade. Business still continues brisk, and large cargoes to coaling ports and foreign destinations have been very marked, especially from Cardiff, the Knight of St. George taking 6000 tons to Bombay, and the Avondale 5000 tons to the same destination. Mid-week three large cargoes of 5000, 4000, and 2400 tons were dispatched to Colombo, and consignments of between 3000 and 3500 tons were common to Rio, Aden, and elsewhere. A strong opinion prevails in coal circles that naval and military events of importance are looming.

Attendance on 'Change, Cardiff, has been well maintained, and prices continue satisfactory. Mid-week best steam coal was in good demand at 10s. to 10s. 3d., and the inquiry for good seconds looked well, best being quoted at 9s. 9d. to 10s., and even ordinary from 9s. 3d. to 9s. 6d. For dry coal there was little demand. Prices:—8s. 9d. to 9s., and for small steam coal only slight inquiry, prices ranging from 3s. 3d. to 4s. 9d., according to quality. In house coal little improvement was shown, and prices remain practically the same as last week:—Best households, 10s. to 10s. 3d.; No. 3 Rhondda, 9s. 6d. to 9s. 7½d., brush, 7s. 9d. to 8s.; small, 6s. 3d. to 6s. 6d.; No. 2 Rhondda, 7s. to 7s. 6d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Swansea prices:—Anthracite, 8s. to 11s. 6d., according to quality; steam, 9s. to 10s.; bituminous, 9s. 6d. to 10s.; No. 2 Rhondda, 8s. 6d. to 9s. 6d.; small, 5s. to 5s. 3d.

Patent fuel is in moderate demand. Cardiff prices, 10s. to 10s. 3d. Swansea, 9s. 9d. to 10s. 3d. Coke maintains a firm tone. Cardiff prices: Furnace, 13s. to 15s.; foundry, 15s. 6d. to 16s. 6d.; special, 19s. to 19s. 6d. Pitwood continues the same, 14s. 9d. to 15s., ex-ship. Merchants in Cardiff are complaining of the scarcity of berths to discharge pitwood in, and also of the length of time it takes wagons to be transferred alongside steamers. I hear that the leading men in the trade are about to petition the dock authorities upon the matter.

The iron ore market is steady as regards prices, and a fair inquiry exists. Cargoes have again been numerous this week; Dowlais receives six, Cyfarthfa one, Blaenavon two, Ebbw Vale, one, and the Patent Nut and Bolt Company one.

This week most of the Cardiff notables are in London, taking part as speculators in the great railroad schemes.

The first of the important Welsh Bills came before the House of Lords Committee this week. This was the Great Western Additional Powers Bill. Mr. Pope put this very concisely as consisting of two objects, the making of a branch line on the Great Western Railway, near Pengan station, to the new Bute Docks at Cardiff; and the other the amalgamation of the Marlborough line with the Great Western. The claim of the Great Western was to have an independent connection with the Bute Docks. The Bill was only opposed by the Taff Vale Railway. Mr. Wilkinson, assistant manager of the Great Western, was the first witness called, and stated that his company carried about a million tons a year of coal to the Bute Docks, the Taff Vale Railway four and a-half millions, and the Rhymney Railway Company about two and a-half million tons. The traffic from the Monmouthshire Valley had greatly increased of late, because, probably, of a better price being obtained at Cardiff. Ten new sinkings in the Monmouthshire coal field are projected.

After a good deal of pertinent evidence by supporting witnesses, and oppositional by Taff Vale witnesses, the room was cleared, and on readmittance of the public, the chairman stated that the committee approved of the preamble of the Bill, as far as it applied to No. 1 Railway, on condition of certain concessions to the Taff. This gives the Great Western Railway all it desired, an independent line from Pengan to the Bute Docks.

On Tuesday the Barry Railway Bill was brought forward, opposed by the Rhymney, Taff Vale, Bute Docks, and others.

This may be briefly described as an attempt on the part of the Barry to reach the Monmouthshire coalfields. For two years this has been attempted by means of a new railway through East Glamorgan. The tactics are now changed, and if successful, all the company then required will be obtained at a less cost. The proposal now is to make a railway from St. Fagans to Walnut Tree Junction, and thus join up the Rhymney system with their own, and, to complete their requirements, running powers over the Rhymney at the junction, over the Great Western at Llanbradach, and over the Taff Bargoed Railway, and a line from Walnut Tree into the Aber, where new collieries are being sunk. This promises to be a severe and an interesting struggle, and will bring out on all sides very marked ability.

I notice that Sir William Lewis, Bart., is in his usual place, and that in addition to Mr. D. Morgan, of the Docks, a strong addition to his staff is present in Mr. James Hurman, formerly of the Taff Vale Railway, and notable for his ability in parliamentary conflicts.

The Cardiff Exhibition is to open on May 2nd, and promises to be of interest to the engineering world. The principal railways will be represented by useful models, the electric world by a great number of the latest inventions, light and power, some of which are making their way in pit work. I am informed, and have been favoured with an inspection of an interesting list of special value to the maritime world, canals, bridges, piers, &c., and propose, as the exhibition progresses, and goes through its course of evolution, to notice the most striking contributions. Art, as well as industry, is to be represented, and amusement will form a special attraction.

It is stated by Mr. Dalziel, secretary for the metal trades section of the Cardiff Exhibition, that the Dowlais Company will be represented, amongst other notable productions, by a steel plate, which has been sent in, weighing 8600 lb., and measuring 70ft. in length. The plate was rolled at the company's Cardiff branch, and is the longest ever manufactured. Some very large steel ingots are promised by the same firm, so it is evident that the metal trades section will be an interesting one.

The Hannibal, the largest vessel ever built at Pembroke Dockyard, was successfully launched on Tuesday. The ship has been built from designs by Sir William White, under the supervision of Mr. H. Cock, chief constructor, &c., and at a cost, it is stated, of £1,000,000. Tonnage, 14,900 tons; extreme length, 420ft.; breadth, 76ft. 6in.; depth, 46ft.

There is moderate animation in iron and steel.

The rail dispatches of the week include 960 tons from Newport, Mon., to Hobart, a small consignment to Dublin, and 200 tons to Southampton.

I note that figures are slightly easier. Swansea quotations this week are:—Steel rails, heavy, £4 7s. 6d. to £4 12s. 6d.; light, £4 15s. to £5 5s. Pig iron has fluctuated a good deal, but the latest report is that prices are 6d. better. In copper a slight improvement; block tin unaltered.

Other Swansea quotations are as follows:—Middlesbrough pig, No. 3, 38s. 3½d.; hematite, 45s. 8d.; Welsh bars, £5 10s. to £5 12s. 6d.; sheet iron, £6 15s. to £6 17s. 6d. at works; steel sheets, £6 10s. to £6 12s. 6d.; Bessemer steel bars, £3 17s. 6d.; Siemens, £3 18s. Tin plates: Steel coke, 9s. to 9s. 1½d.; Siemens, 9s. 1½d. to 9s. 3d.; ternes, 16s. 6d., 17s. 6d. to 22s. 6d.; best charcoal, 12s. 6d. to 12s. 9d.; wasters, 6d. to 1s. less.

I regret having no improvement to record in tin-plate. There is a slightly better inquiry for tin bars, I am informed, and hopes are held out in good quarters that the "corner is being turned," though slowly. I see that Llanelly is sending black plates to Ghent, and tin-plates coastwise to Cardiff. The latest Swansea report is that shipments have been small, and stocks had increased. The output has been curtailed a good deal by the stoppage of mills, so that demand and make are getting fairly equal. Some Morristown men are emigrating. A little better tone prevails at Briton Ferry. The Gwalia has restarted on a reduction of 15 per cent., and three mills at the Villiers will start on the same terms. The main shaft of the engine driving the other three has broken, and this will entail delay and a cost, I hear, of £1000.

A movement is on foot to make Cardiff a first-class port.

With reference to my paragraph in THE ENGINEER last week concerning Cyfarthfa Works and its representation in London, I find on making inquiries that the London office of the Messrs. Crawshay Brothers, Cyfarthfa, will remain at the same address as heretofore, and that no change in this direction is contemplated.

"Old" Dowlais Works are going in for additional electric light and power.

I regret to announce the death of Mr. H. J. Vose, superintendent engineer—telegraphs—for South Wales. In the coal world, Mr. E. Beddoe figures in the obituary, son of one of the pioneers in the well-known Mynyddyslwyn seam in Monmouthshire.

Early in May the compact engineering works at Ystalyfera are to be brought to the hammer.

The vacant position of secretary to the Taff Vale Railway has not yet been filled. One name discussed is that of Mr. George Robertson, who had the appointment some years ago, but retired in order to join a steamboat company. I remember that his retirement was much regretted. He had worked up from the juniors.

The consignment of 3000 tons of sulphide ores from South Australia is to be treated by a new process at Llansamlet, where works are being fitted up by a new company. The place will be in direct contact with the Midland Railway.

Swansea dispatched 2400 tons of anthracite to California last week.

Some degree of friction continues amongst the Plymouth colliers. I hope it will disappear with the month.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

BOTH on home and foreign account a good demand has been experienced upon the week, and the brisk activity that has for some time past characterised the various departments of the iron trade has been well maintained.

With regard to the position of the iron market in Silesia, only the most favourable accounts are given. The firm tendency in prices continues, although for some articles demand has perhaps been a trifle less lively than last month. Export in nearly all articles of iron and steel has undeniably improved, and a confident tone is generally to be perceived among producers as well as consumers. Local demand for malleable iron and steel has also been pretty good; both the bar and the girder mills have booked orders that reach far into the third quarter, and there is much firmness shown with regard to quotations.

The Austro-Hungarian iron trade is in about the same condition as before, the various departments of the iron and steel trade being satisfactorily employed. Foreign competition is less keen than formerly, and as there is a decided increase in consumption, both on home and on foreign account, the tone of the iron market is naturally pretty strong. The hardware business, which was somewhat weak hitherto, has perceptibly improved just lately. The convention of the Austro-Hungarian rail works are stated to have produced in 1895, 55,700,000 kilos. rails, against 51,400,000 kilos. in 1894, 46,500,000 kilos. in 1893, 44,000,000 kilos. in 1892, 58,000,000 kilos. in 1889, 94,200,000 kilos. in 1883, 44,800,000 kilos. in 1879. The said convention was formed in 1879.

Every branch of the French iron trade seems busy, orders coming to hand freely. There is no alteration to be noted in prices, which remain firm all round, with a slight inclination to advance where orders for immediate delivery are concerned.

The reports from the Belgian iron market are exceedingly gratifying, raw as well as manufactured iron and steel selling briskly. Some rather heavy orders have been booked during the past week. There is not much of interest to be related in connection with the Belgian coal market. Prices are firm, best steam coal fetching 11f. p.t., while house coal is sold at 12·50f. to 14f., and in some instances even 15f. p.t., small coal is quoted 6·75f. to 8f. p.t. according to quality. Regarding the Belgian business in coal and coke during the first two months of present year, import was 269,435 t., against 204,918 t. for the same period the year before; of which, 158,170 t. came from Germany, against 96,724 t. last year; import in coke amounted to 34,417 t., against 60,640 t.; 31,715 t. coming from Germany, against 59,578 t. for the same period the year before. Belgian export in coal amounted to 735,041 t., against 784,434 t. for the same months in previous year; 33,913 t. were sent to Germany, against 44,272 t. last year; 559,473 t. were exported to France, against 622,885 t. last year. In coke, export amounted to 140,639 t., against 142,018 t.; 16,720 t. going to Germany, against 26,270 t. for the same period the year before. Export in coke to France amounted to 83,768 t., against 61,218 t. for the same months in previous year.

Throughout the iron and steel trades of Rheinland-Westphalia new work continues to come forward freely; all the leading establishments are not only fully engaged, but there is work in hand to keep them going for many months ahead. A very firm tone prevails, consequently, in all departments. Brisk activity is going on at the iron ore mines of the Siegerland and Nassau; in the first-named district output is, on an average, 8000 t. higher than at the end of last year; here and there inquiries have already been coming in for the fourth quarter. In spite of the healthy business that has of late been doing in inland ore, large quantities of foreign ore continue to be thrown on the market, and generally meet with ready demand. The prices quoted last week for Siegerland ore were as follows:—Spathose iron ore, M. 9 to 9·60 p.t.; roasted ditto, M. 12 to 13·70 p.t.; calcined iron ore, M. 12 to 14 p.t.; Nassau red iron ore, 50 p.c. contents, fetches M. 9·30 p.t. net at mines; for the third quarter, M. 9·50 p.t. is asked. Minette of Lorraine is quoted M. 2·60 to 2·80 p.t.; the 40 p.c. quality realising M. 3·40 p.t. net at mines. The business in pig iron has been exceedingly brisk upon the week, and the blast furnace works are consequently very busy; a further increase in demand is expected. Prices, which may now be considered in just proportion to those of the raw material, are firmly maintained, and generally exhibit a rising tendency. Spiegeleisen, 10 to 12 p.c. grade, notes M. 58 to 59 p.t.; forge pig, No. 1, M. 53 to 55 p.t.; No. 3, M. 42 p.t.; hematite, M. 65 p.t.; foundry pig, No. 1, M. 65; No. 3, M. 57 p.t. Basic is generally sold at M. 56 p.t.

German Bessemer steel stands on M. 60 p.t.; while Luxemburg forge pig is quoted 56f. p.t. free Luxemburg. A very satisfactory state of things can be reported in the malleable iron industry. Bars and girders are specially brisk, and makers are well sold forward. In spite of a very keen competition from foreign markets, girders have been raised M. 3 p.t. last week. The position of the plate business has further improved, heavy plates realising M. 5 p.t. more than previous week. Sheets continue in very good call generally, and there is also little more life stirring in the hoop trade. Wire and wire nails are still in languid demand, and this tends to give a certain weakness to prices. In rivets, on the other hand, there has been a slightly better tone noticeable of late, and prices are stiffening. Machine and construction shops are pretty fully engaged, and so are the foundries.

Last week's list quotations per ton at works were as under:—

Good merchant bars, M. 118; angles, M. 128; girders, M. 94 to 97; billets in basic and Bessemer, M. 84 to 85; hoops, M. 123 to 125; heavy plates, for boiler-making purposes, M. 160 to 165; tank ditto, M. 135 to 140; steel plates, M. 130 to 135; tank ditto, M. 120 to 125; sheets, M. 137 to 150; iron wire rods, common quality, M. 125; drawn wire in iron or steel, M. 118 to 138; rivet iron, M. 138 to 142; rivets, M. 175 to 180; wire nails, M. 127 to 130; complete sets of wheels and axles, M. 280 to 290; axles, M. 220; steel tires, M. 200; Bessemer rails, M. 118; steel sleepers, M. 110; fish-plates, M. 120 to 130; light section rails, M. 100.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

GOOD attendance on 'Change. The demand for steam coal is fairly good, and prices for best quality firm. House coal shipments continue good with prices unchanged. Tin-plates in fair inquiry. The demand for manufactured iron and steel continues good.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s. to 10s. 3d.; dock screenings, 5s. to 5s. 3d.; colliery small, 4s. 6d. to 4s. 9d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s. 5d.; hematite warrants, 48s. f.o.b. Cumberland; Middlesbrough No. 3, 38s. 1d. prompt; Middlesbrough hematite, 45s. 7d. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s.; Siemens, coke finish, 9s. 3d.; ternes, per double box, 28 by 20 C, 18s. 6d. to 20s. Pitwood, 15s. 3d. to 15s. 6d. London Exchange telegram: Copper, £45 5s.; Straits tin, £59 13s. 9d. Freights, firm.

BERLIN EXHIBITION.—For the convenience of visitors to the Berlin Exhibition the South-Eastern Railway Company have arranged to issue first and second-class return tickets from London to Berlin by the 8.15 p.m. service *viâ* Ostend and *viâ* Calais on Tuesdays and Fridays only, at practically the single fare for the double journey. The special return tickets, which will be available fifteen days, will be ready early in May and issued during the period of the exhibition.

MOVEMENT OF THE GOUFFRE MOUNTAIN.—Owing to the movement towards the river Gardon of the Gouffre Mountain, near the Grand' Combe Colliery, in the French Department of the Gard, which has completely interrupted railway communication, the Bessèges Municipal Council passed a resolution calling on the P.L.M. Company to make a new railway between Bessèges and Chamborigaud. Inasmuch, however, as that company imposed full kilometric rates for carrying coal by a circuitous route from the Kescol and Champclauson collieries, the Grand' Combe Company decided to construct a new line on the right bank of the Gardon. Although the additional railway rates have been suspended, the Grand' Combe Company announces that its new line will be pushed on as fast as possible.

AMERICAN NOTES.

(From our own Correspondent.)

NEW YORK, April 23rd.

SYMPTOMS of increasing confidence in the commercial situation are appearing. There are greater investments of both home and foreign capital in securities, railroad and industrial, and a healthy activity in mining circles. The political whirlpool is getting into shape, so that the business interests are beginning to discount probabilities. A Protection President will be elected. A party split will occur in both conventions, three presidential candidates will fight for the White House, and the Republicans will win. Quick remedial legislation will follow, and decreased imports will soon tell the tale that the American people have wakened out of their nap. The iron trade is not very active. Coke and ore makers are prancing around with their high prices, and consumers are distrustful. Billets are not bought freely at Pittsburgh just now, but requirements are large, and an enormous demand must soon set in if prospects are real and not illusory. Pig iron production is still in excess of consumptive requirements, but for all that prices have ruled firm. Southern freights have advanced a trifle, and a spirit of combination is cropping out to keep prices up by restricting production. In finished products there is only moderate activity. Prices are firm, especially in all Western markets, where general business is better. Plates and structural material are particularly active. Railway equipment sells slowly, and rolling stock, though badly needed, is not ordered. Steel rails in heavy sections are dull, though light sections and girder rails have been selling quite freely. Ship and boat yards are all crowded, and machine shop work is improving.

LAUNCHES AND TRIAL TRIPS.

The s.s. Imperialist was launched from the yard of Messrs. William Doxford and Sons, of Sunderland, on the 25th April, having been built to the order of Messrs. Angier Brothers, London, under the superintendence of Mr. F. J. Pilcher, Liverpool.

The steam yacht Latona, of 265 tons, yacht measurement, designed and built by Day, Summers and Co., of the Northam Ironworks, Southampton, for Baron A. W. von Knoop, was launched on the 29th April. Length, perpendiculars, 136ft.; length on load water line, 135ft.; breadth, 20ft. 3in.; depth, 13ft. The engines are of the compound inverted surface condensing type, of 60-horse power nominal, the cylinders being 18in. and 35in. diameter by 24in. stroke, and boiler 10ft. 6in. diameter by 9ft. long, working pressure 90 lb.

On April the 27th Messrs. Ropner and Son, of Stockton-on-Tees, launched a steel screw steamer of the following dimensions, viz:—Length between perpendiculars, 314ft.; breadth, extreme, 44ft.; moulded depth, 23ft. 3in., which they have built to the order of Messrs. George Pyman and Company, West Hartlepool. The vessel is built on the single-decked rule, "with freeboard," having half poop, bridge, and topgallant forecastle, her deadweight carrying capacity being 4100 tons on 19ft. The saloon and cabins for captain and officers are fitted in the poop, the engineers' accommodation being under the bridge amidships. She is built on the web frame principle, leaving the holds entirely clear for cargo, and carries her water ballast in a cellular bottom and in the after peak. All labour-saving appliances are fitted for the economical working of the steamer, and also for the expeditious loading and unloading of cargoes. She has steam steering gear amidship and screw gear aft, four powerful steam winches, two large donkey boilers, direct steam windlass, stockless anchors, &c. The engines will work up to about 1000 effective horse-power, and are by Messrs. Blair and Co., having cylinders 23in., 37½in., and 61½in. by 39in. stroke, steam being supplied by two large steel boilers working at 160 lb. pressure. The name of Veva was given to her as she left the ways, the naming ceremony being performed by Miss Eva Pyman.

On Saturday morning last the s.s. Ebani left the port of Hartlepool for her trial trip. The vessel has been built by Messrs. Wm. Gray and Co. to the order of the African Association, of Liverpool, for their line of steamers between that port, the Continent, and the West Coast of Africa. She is a handsomely-modelled steamer of the following dimensions:—Length over all, 270ft.; breadth, 36ft. 2in.; and depth, 22ft. 8in. The vessel takes Lloyd's highest class, is built of Siemens-Martin mild steel, with poop for passengers, having well-lighted berths and saloon most tastefully fitted up, smoking-room above, and a luxurious chart-room. The engineers' and officers' rooms are amidships in the long bridge, and the crew's berths in the topgallant forecastle. An ice-room is fitted under the deck, and electric bells in the cabin. An electric light installation has been provided for lighting the vessel throughout. A cellular double bottom is fitted throughout for water ballast. The engines have been supplied by the Central Marine Engine Works of Wm. Gray and Co., and they are of the triple-expansion type, of 1200-horse power, having two large steel boilers working at a pressure of 160 lb. per square inch. There is also in the engine-room electric light machinery, Mudd's patent evaporator, triple automatic telegraph, and other specialities for the economical and convenient working of the machinery. After adjusting compasses the engines were put full speed ahead, and the vessel ran to the south almost as far as Whitby, and back again to Hartlepool, when the speed was found to be 11½ knots per hour. The engines ran in a most excellent manner, there being no heating of bearings, and the boilers kept a steady head of steam with easy firing. Before leaving the harbour the vessel had been carefully inspected by Mr. Holt, chairman of the African Association, and there were present at the trial Mr. Tunnicliffe, one of the directors of the African Association, and Mr. E. H. Bushell, the superintendent engineer, under whose supervision the vessel and her machinery have been constructed. Captain Murrell represented the builders of the ship, and Mr. T. Mudd the engine builders. On the conclusion of her trial the vessel proceeded round to Liverpool, where she loads her first cargo for the African Coast.

THE PATENT JOURNAL.

Condensed from "The Illustrated Official Journal of Patents."

Application for Letters Patent.

*** When inventions have been "comunicated" the name and address of the communicating party are printed in italics.

15th April, 1896.

7969. Manufacturing Anhydride, J. Enright, London.
7970. Attachment for Ladies' Skirts, C. E. Green, London.
7971. Utilising Grains, S. Pratt, London.
7972. Instrument for Measuring Angles, L. K. Bell, London.
7973. Electrical Accumulators, A. Heil, London.
7074. Hot Water Heating Apparatus, G. L. Berry, London.
7975. Attaching Articles, W. P. Thompson.—(*F. Loos, Germany.*)
7976. Drive Chain, A. Appleby, Birmingham.
7977. Coating Paper, H. W. V. Wilson and W. Brown, Liverpool.
7978. Signalling on Steamers, J. H. Latham, Liverpool.
7979. Fastening Ladies' Veils, J. Mansergh, Liverpool.
7980. Fastenings for Slip-hooks for Traces, A. Wood, London.
7981. Safety Corking of Bottles, &c., L. Vézac, London.

8061. Dies for Making Gas Retorts, W. P. and G. B. A. Gibbons, Birmingham.
8062. Electric Railways, P. W. T. Davies, London.
8063. Mud Guards, R. Bowes, Liverpool.
8064. Treating Sulphide Ores, T. Huntingdon and F. Heberlein, London.
8065. Regenerative Furnaces, S. Pitt.—(*H. L. Gantt, United States.*)
8066. Looms, R. L. Hattersley, S. Jackson, and B. Walker, Bradford.
8067. Magneto-electric Governing Appliance, R. P. Wilson, London.
8068. Magneto-electric Regulating Appliance, R. P. Wilson, London.
8069. Treating Fibrous or Pulpy Materials, J. B. Ker, London.
8070. Pocket Scissors, S. and F. Jones, F. S. Howard, and W. A. Higginson, London.
8071. Wheel or Roller Skates, J. du P. Sworder, London.
8072. Treating Ores, W. T. Whiteman.—(*The Compagnie Générale l'Alumine Exploitation des Brevets F. Raynaud (Société Anonyme), Belgium.*)
8073. Covering Roadways, &c., S. O. Cowper-Coles, London.
8074. Bicycles, C. F. A. H. Bagot, London.
8075. Explosives, M. I. E. Morris, London.
8076. Automatic Guns, H. S. Maxim and L. Silverman, London.
8077. Hose Pipe Couplings, H. H. Lake.—(*I. P. Doolittle, United States.*)
8078. Asbestos Fabric, J. Germain and L. and H. Boisne, London.
8079. Foot Scrapers and Cleaners, R. J. Trumbull, London.
8080. Accumulator, E. Commelin and R. Viau, London.
8081. Torpedoes, L. H. Moulun, London.
8082. Stamping Apparatus, J. Bohensky, London.
8083. Holding a Looking-glass Inclined, E. M. A. Fraser, London.
8084. Pinion Teeth, C. D. Abel.—(*R. Abt, Switzerland.*)
8085. Operating Bulkhead Doors, D. Munro, London.

17th April, 1896.

8086. Skirts, J. Westaway, London.
8087. Vessels for Cooking Liquids, J. Westaway, London.
8088. Cooking Vessels, J. Westaway, London.
8089. Outlet Valve Motion, W. Seck, Frankfort-on-the-Main.
8090. Ice Cream Cart, B. Twigg and C. H. Bennett, Sheffield.
8091. Serving Ice Cream, B. Twigg and C. H. Bennett, Sheffield.
8092. Utilising Tires of Wheels, J. C. H. Pierson, London.
8093. Filter, &c., H. E. Fry and N. G. Hackney, London.
8094. Brackets, W. Thomson, Huntingdonshire.
8095. Spindles of Yarn-twisting Frames, R. Fischer, Manchester.
8096. Automatic Air-escape Valves, T. C. Olney, Manchester.
8097. Hopper-feeding Machines, D. Armstrong and J. Ashton, Manchester.
8098. Treating Furnace Gases, W. H. Hill-Hartland, Sheffield.
8099. Coin-freed Machine for Stamps, F. J. Shapley, Bristol.
8100. Bedstead Loose Fitting, J. and F. S. Turner, Dudley.
8101. Boot Stretchers, T. Morton and F. R. Baker, Birmingham.
8102. Locking Corks in Bottles, W. W. Cashmore, Birmingham.
8103. Preventing Noise from Gas Engines, O. Y. Rhodes, Leeds.
8104. Looms, A. Johnstone and J. W. Parker, Bradford.
8105. Automatic Receiver of Mails, T. Knowles, jun., Sunderland.
8106. Twyer Stone, C. A. Brackelsberg, Brussels.
8107. Appliances for Circulating Water, J. Laird, Glasgow.
8108. Furnaces for Steam Boilers, O. Meredith, Birkenhead.
8109. Band for Cycle Tires, D. W. Andrews, Manchester.
8110. Shaking-barrel, A. J. Leaver, London.
8111. Apparatus for Shaping Bread, J. P. Killeen, Dublin.
8112. Grinding Spectacle Lenses, G. Prescott, Dublin.
8113. Portable Rotary Blower Pump, E. Samuelson, Banbury.
8114. Reservoir for Supplying Ink, J. Joly, Dublin.
8115. Apparatus for Water-heating, W. Mycock, Rochdale.
8116. Facilitating the Opening of Boxes, P. W. Watts, Manchester.
8117. Winding Regulator, W. Whittaker and J. H. Fanton, Manchester.
8118. Punches for Tickets, J. Macrae and W. Clark, Glasgow.
8119. Vacuum Milking Machines, A. Shiels, Glasgow.
8120. Apparatus for Sweeping Chimneys, T. Flynn, Glasgow.
8121. Border for Garden Walks, J. C. Meyers, Dublin.
8122. Process for Clarifying Beer, E. and C. Müller, Berlin.
8123. Letter-boxes, D. and S. Cristol, London.
8124. Measuring Appliance, C. V. du Toit, London.
8125. Driving Gear for Cycles, F. Peters, London.
8126. Clearing Ships of Water, E. E. Middleton, Essex.
8127. Cycle Brakes, F. P. Craven, London.
8128. Cycle and other Lamps, J. A. Hay, Birmingham.
8129. Seats, S. D. V. Meter, Birmingham.
8130. Weather Guard for Cyclists, G. J. D. Coleridge, London.
8131. Incandescent Gas Lamps, A. H. Catherwood, London.
8132. Roughing Screws for Horseshoes, E. Dejean, London.
8133. Penholders for Ruling Purposes, G. Thompson, London.
8134. Electrical Welding Process, L. W. Breuer, London.
8135. Pneumatic Tires, J. T. Trench, London.
8136. Pneumatic Tires, J. T. Trench, London.
8137. Mudguards for Velocipedes, I. W. Boothroyd, London.
8138. Attachments to Cycles, &c., R. Corsham, London.
8139. Seed and Manure Drills, W. Brenton, London.
8140. Cultivators, E. Mote, London.
8141. Switch Apparatus, Siemens Bros. and Co.—(*Siemens and Halske, Germany.*)
8142. Apparatus for Superheating Steam, B. Jaffé, London.
8143. Mounting of Photographs, S. Delépine, London.
8144. Auto-harps, J. A. Taylor, London.
8145. Speed Gears, S. H. Crocker, London.
8146. Curve Tracers and Rulers, E. B. Noyes, London.
8147. Can Openers, J. A. Haskett, London.
8148. Decoration of China, The Coalport China Co., and T. J. Bott, London.
8149. Burner for Incandescent Lighting, E. Ernst, London.
8150. Combined Billiard Marker, R. B. Pearson, London.
8151. Burners for Liquid Combustibles, L. Runge, Liverpool.
8152. Process for Preserving Eggs, A. Huber, London.
8153. Closing Devices for Bottles, G. Labuthie, London.
8154. New Acid, J. C. Mewburn.—(*The Chemische Fabrik von Heyden, Gesellschaft mit beschraenkter Haftung, Germany.*)
8155. Utilising Space under Seats in Churches, H. Anderson, London.
8156. The T Curtain Hook, J. E. Doughty, London.

8158. Lathes, W. V. Pittler, London.
8159. Stoppering Bottles, &c., G. Elsley and R. Hill, London.
8160. Cycles, F.-H. R. B. Liebenrood, London.
8161. Combustion of Fuel, W. Tyree, London.
8162. Rat Traps, W. Tyree, London.
8163. Operating Electric Signals, L. Mesmer-Weber, London.
8164. Buttons, J. H. Nancarrow, London.
8165. Cycles, W. S. Simpson, London.
8166. Linotype Machines, The Linotype Company.—(*The National Typographic Company, United States.*)

18th April, 1896.

8167. Tramway Track or Rail Cleaner, J. T. Warren, Bristol.
8168. Securing Elastic Tires to Wheels, J. Adair Waterford.
8169. Incandescent Gas Lamps, P. Meyer, London.
8170. Trawling Gear, G. A. Smith and W. J. Baker, Scarborough.
8171. Sanitary Closet Seat Pad, L. W. Caulfield, Brighton.
8172. Weaving Wire, D. S. Birrell and A. Rathbone, Liverpool.
8173. A New Game, H. O. and J. O. Roberts, Gloucester.
8174. Articles of Dress, W. F. Quinn and J. Taylor, Leicester.
8175. A Unicycle, J. Pledger, London.
8176. Furniture Castors, C. E. Dunn, Birmingham.
8177. Cleaning Out Tubular Bends, J. W. Banks, Belfast.
8178. A Collapsible Boat, A. H. K. Smith, Portsmouth.
8179. Tobacco Pipes, A. H. Gorsuch, J. Crowther, and G. H. Richmond, Manchester.
8180. Manufacture of Mats, F. Armitage and W. Hirst, Huddersfield.
8181. Opening Closed Vessels, H. Austin, Wolverhampton.
8182. Fire-arms, E. T. Whitelow.—(*A. W. Schwarzlose Germany.*)
8183. Swimming Appliances, W. Snaydon, Dorsetshire.
8184. Cloths for Cleaning Purposes, S. O'Neill, Lancashire.
8185. Lowering Gas Fittings, P. G. Ebbutt, Birmingham.
8186. Cycles, J. W. Smallman, Nuneaton.
8187. Sewing Machines, W. H. Inslee.—(*The Singer Manufacturing Company, Germany.*)
8188. Stone Cutters' Chisels, J. Mellon, Glasgow.
8189. Tires of Cycles, J. McConechy, Glasgow.
8190. Manufacture of Driving Belts, J. K. Tullis, Glasgow.
8191. Outside Blinds for Shop Windows, J. R. Malcolm, Dundee.
8192. Furnaces, A. Hope and W. Arnold, Manchester.
8193. Woven Wire Mattresses, F. G. Gale, Birmingham.
8194. Manufacture of Margarine, J. C. Uhlenbrock, Manchester.
8195. Wearing Apparel, J. Tenebaum, Liverpool.
8196. Ready-made Seal for Deeds, J. L. Phillips, Llanelly.
8197. Ramming of Ships, R. J. Plunkett, Bristol.
8198. Hydraulic Apparatus, A. S. Bryce, jun., Glasgow.
8199. Four-wheeled Road Vehicles, J. H. Kelly, Glasgow.
8200. Window Tickets, A. Macdonald, Glasgow.
8201. Two-speed Gearing for Cycles, A. Dicksee, London.
8202. Flexible Transmission Shafts, E. L. Doyen, London.
8203. Steering Gear, J. Brown, Glasgow.
8204. Wrapper for Paste Blacking, A. E. Pinfold, Bradford.
8205. A Puzzle, W. Percival and A. E. Pinfold, Bradford.
8206. Cycle Gear Cases, H. Fearncombe and Co., Ltd., and A. Evans, London.
8207. Braces, H. H. Leigh.—(*Plener and Co., Germany.*)
8208. Troughing for Electric Wires, J. Row, Manchester.
8209. Hooks for Securing Veils, H. Broughton, London.
8210. Controlling the Feed in Arc Lamps, H. J. Fisher, London.
8211. Flower Holder, H. G. Perring, London.
8212. Tobacco Pouch and Pipe Case, P. E. Ward, London.
8213. Combined Washstand and Bed, J. J. Huygens, London.
8214. Preventing Liquids in Pipes Freezing, G. Stevens, London.
8215. Refrigerators for Eggs, &c., J. H. Bowley, London.
8216. Electric Motors and Dynamos, W. E. Gray, London.
8217. Jacquard Apparatus, J. Szczepanik and L. Kleinberg, London.
8218. Boots and Shoes, G. A. Royce and F. Knight, London.
8219. Trees for Boots, &c., G. A. Royce and F. Knight, London.
8220. Tape Lines, S. H. Rodick, London.
8221. Knitting-machine Lock Mechanism, H. Verges, London.
8222. Coupling Railway Vehicles, H. S. Frampton, London.
8223. Dolly for Laundry Purposes, W. Cree, London.
8224. Improved Laundry Washing Board, W. J. Jones, London.
8225. Golf Clubs, F. A. Ayers and G. Buckoke, London.
8226. Hardening Metal Articles, W. S. Simpson, London.
8227. Treating Sewage, W. D. Scott-Moncrieff, London.
8228. Electric Generators, Siemens Bros. and Co., Ltd., and E. F. H. H. Lauckert, London.
8229. Railway Carriage Couplings, J. L. J. Linou, London.
8230. Pneumatic Tires, A. J. Boult.—(*F. H. Snow, Australia.*)
8231. Weighing Apparatus, F. Williams, London.
8232. Preservation of Perishable Goods, H. Higgins, London.
8233. Hermetic Sealing of Vessels, H. Higgins, London.
8234. Prepayment Gas Meters, L. S. Burchard.—(*W. Webber, United States.*)
8235. Producing Designs on Linen, &c., J. Weiss, London.
8236. Material for Destroying Insects, C. H. Higbee, London.
8237. Recording Variations in Rotating Bodies, J. S. Raworth, London.
8238. Waistbands for Knickerbockers, J. Royle, London.
8239. Producing Illuminating Gas, C. Gautzsch, London.
8240. Incandescent Gas Stoves, S. H. Crocker, London.

20th April, 1896.

8241. Gas Globes and Shades, W. H. Prestwich, London.
8242. Spinning Frames, W. P. Thompson.—(*Christiania Seildugsfabrik and A. Pein, Norway.*)
8243. Steel Tube Tire for Cycles, W. G. Brightling, London.
8244. School Slates, E. Burke, Dublin.
8245. Governor Meter, W. G. Potter, London.
8246. Collar Studs and Solitaires, M. Bennett Swansea.
8247. The Bunsen Retort Superheating Gas Burner, M. F. Solon and Marquis Bibbero, Cobridge, Staffordshire.
8248. Pegs for Loom Shuttles, B. Garlick and J. Ellis, Huddersfield.

8249. Governing Marine Engines, D. Johnston and W. McAdam, Glasgow.
8250. Valves, T. O'Hara and J. R. and T. Ashmore, Liverpool.
8251. Decorating Tiles and Plaques, R. Lunn, Derby.
8252. Combination of Easel Show Cards, T. Morton, Birmingham.
8253. Cycles, W. A. D. Hipperling, C. P. T. Engels, G. C. W. Hipperling, and F. C. H. Klare, Berlin.
8254. Ladies' Cycling Dresses, J. W. Boyce, Cheltenham.
8255. Mechanical Motors, J. O. Dale, Birmingham.
8256. Cork Armoured Pneumatic Tire, V. de H. Dowler, Plaistow.
8257. Hose Pipe Couplings, H. G. Fraser, Dundee.
8258. Cop Shuttles, J. Ireland, Dundee.
8259. Ventilation of Coal Mines, W. G. Thomas, Liverpool.
8260. Driving Motor Vehicles, J. Fielding, Gloucester.
8261. Mechanical Toys, G. Royle and W. R. Wynne, London.
8262. Tightening Wires, M. Commichau, Zwickau, Saxony.
8263. Springs for Wheels, H. W. McWm. Bourke, London.
8264. Socket for Handle Bar of Cycles, J. Loftos, London.
8265. Flushing Closets, T. G. Rhodes, R. Gaunt, and J. B. Ledgard, London.
8266. Trussing Knives, Hay Knives, &c., T. A. Linacre, Sheffield.
8267. Manufacturing Varnish, E. W. Barnsley, Birmingham.
8268. Increasing Speed of Screw Propellers, W. White, London.
8269. Electrical Conductors, &c., G. Wilkinson, London.
8270. Hollow Rubber Tires for Wheels, I. E. Clifford, London.
8271. Electric Traction, W. S. Boult, London.
8272. Word-making Game, A. Walker, London.
8273. Boilers, J. G. Nash and J. M. Borrow, London.
8274. Grading Machines, W. Johnson and H. Walker, London.
8275. Closing Puncture Holes, &c., J. G. Horsey, London.
8276. Order Pads, R. J. Cook and W. H. C. Hammond, London.
8277. Tubes, J. Hudson, London.
8278. Cutting Tools, G. Cubbon, London.
8279. Registering Amount of Liquids, J. D. Hannah, London.
8280. Drawing-off Liquids under Pressure, N. Caro, London.
8281. Insulating Bricks, S. Pollak and N. Zwillinger, London.
8282. Waste Preventing Spout, W. E. C. Pinchbeck and J. Griffin, London.
8283. Ball Cleaner, C. J. Jacobs, St. Helen's, I.W.
8284. Producing Compressed Air, J. Joetten, Cologne.
8285. Washing and Cleaning Machines, E. J. Lane, London.
8286. Packing Tea, T. Howard, London.
8287. Grinding China, J. Macintyre and Co., Ld., and A. H. Ryles, London.
8288. Producing Ammonia, O. Imray.—(*La Société Christiania Minekompani, Norway.*)
8289. Charcoal for Filtering Oils, G. E. G. Terouanne, London.
8290. Motor Carriage for Railways, W. Hildebrand, London.
8291. Feeding Bottles, A. Haworth, Liverpool.
8292. Milk Cans for Transit Purposes, W. J. H. Buckler, Birmingham.
8293. Billiard Tables and the like, J. S. Burroughes, London.
8294. Automatic Friction Coupling, R. Dahlander, London.
8295. Lifeboats, C. Hibberd, London.
8296. Attaching Spikes to Boots, A. J. Aitkens, London.
8297. Bleaching Paper Pulp, W. H. Caldwell, London.
8298. Manufacture of Tabloids, K. G. Georgi, London.
8299. Propelling Vehicles, &c., J. Wills, Isle of Wright.
8300. Letter Boxes, Money Boxes, &c., J. W. Simmonds, London.
8301. Cycle Adjustable Throw Cranks, W. F. Goreham, London.
8302. Linotype Machines, The Linotype Company, Ltd.—(*The National Typographic Company, United States.*)
8303. Blotter and Calendar, F. J. Measures and F. Adams, London.
8304. Briquette Fuel, C. Bourquin, J. Besson, and P. H. P. C. de Renéville, London.
8305. Fastening Broom Handles, W. Geneger and R. Sanders, London.
8306. Self-propelled Vehicles, L. Bollée, London.
8307. Chicken Rearing Apparatus, A. Bayldon, London.
8308. Electrical Resistances, V. A. Fynn, London.
8309. Manufacturing Hollow Pulp Ware, A. Thame, London.
8310. Improved Prongless Buckle, W. Pritchard, London.
8311. Apparatus for Colour Printing, L. C. G. Lesage, London.
8312. Machines for Chopping Meat, E. Graddon, London.
8313. Protection against Genital Infection, A. Scheuer, London.
8314. Producing Artificial Stone, L. Preussner, London.
8315. Compressing Tobacco, T. Cole and W. L. Cole, London.

21st April, 1896.

8316. Electric Switches, E. H. Wright, J. J. Heckman, A. H. Graves, C. C. Carnahan, and W. H. Carnahan, London.
8317. Navigable Vessels, L. O. Smith, London.
8318. Fixing Dyes in Fabrics, C. M. White.—(*The Electro Waterproofing and Dye-fixing Company, United States.*)
8319. Advertising Clocks, V. I. Feeny.—(*W. F. Mills and L. A. Robertson, United States.*)
8320. Electrical Accumulators, &c., C. Fabbro, London.
8321. Locking Cycle Steering Gear, C. S. Madan, Didsbury.
8322. Cellular Double Bottoms in Ships, G. Gallilee, Hull.
8323. Treating Fabrics, C. M. White.—(*The Electro Waterproofing and Dye-fixing Company, United States.*)
8324. Artificial Decoy Bird, R. M. Presland, sen., London.
8325. Sewing Machines, D. J. MacDonald, Glasgow.
8326. Depositing Copper on Printing Rollers, H. Wylie and J. Grant, Glasgow.
8327. Machines for Cutting Bacon, F. J. Burrell, Thetford.
8328. Artificial Horizons, E. Beecher, Cardiff.
8329. Apparatus for Drying Bottles, T. R. Shercliff, Birmingham.
8330. Animal Shoes, E. R. Rogers and J. Walker, Birmingham.
8331. Metal, F. W. Popp, Birmingham.
8332. Pneumatic Tires for Cycles, W. C. Lister, Wolverhampton.
8333. Wheels, W. H. Caldwell, Dublin.
8334. Wheels, J. Watson, London.
8335. Table Utensils, F. Hadida, Liverpool.
8336. Electric Tramways or Railways, A. G. Adamson, Glasgow.
8337. Castors, E. Smallwood, Birmingham.
8338. Connecting Cars with Wires, W. E. Kenway, Birmingham.
8339. Kitchen Fenders, W. P. Eglin, Halifax.
8340. Automatic Lubricators, F. and J. Thiel and C. Geier, Glasgow.
8341. Velocipedes, J. B. Fondu, Brussels.
8342. Tires, W., W. H., G., and S. E. Lawson, and G. S. Blackburn, Manchester.
8343. Making Wire Fencing, W. Edenborn, Glasgow.
8344. Sorting Minerals, G. Dowson and R. Blakeborough, Stockton-on-Tees.
8345. Appliance for Ladies' Dresses, E. A. Gee, Stockton-on-Tees.
8346. Gas Lamps, A. O. Brown, London.
8347. Bottle Stoppers, V. Reiser and T. Sutcliffe, Bradford.
8348. Refining Oils, J. Y. Johnson.—(*The Ohio Oil Improvement Co., United States.*)
8349. Lath and Venetian Blinds, V. Bennett, Swansea.
8350. Apparatus for Cleaning Windows, J. Sherriff, Glasgow.
8351. Hats, C. L. Lamotte, London.
8352. Treatment of Sewerage, W. H. Higgin, Little Lever, near Bolton.
8353. "Bridgewater" Attachment for Bicycles, B. B. Bridgewater, Hereford.
8354. Engines, A. H. Williams, Glasgow.
8355. Paper-making Machines, J. P. Cornett and F. A. Lindley, Glasgow.
8356. Tools for Drilling Holes, H. Alexander, Glasgow.
8357. Explosive Gas Engines, M. C. Dunsmore, Glasgow.
8358. Riveting Machines, G. W. Parker, Glasgow.
8359. Motor Power Apparatus, J. M. MacDonald, London.
8360 Decorticating Fibrous Plants, J. M. MacDonald, London.
8361. Bottles, G. P. Clark, London.
8362. Electric Signalling Devices, E. J. Devine, London.
8363. Stone Working Appliance, W. Thomas, London.
8364. Claw and Peen Ended Hammer, A. Porter, Bolton.
8365. Fire Iron, H. Carter, Bolton-le-Moors.
8366. Fastener for Boots, A. T. M. Johnson and S. L. Lion, London.
8367. Diamond Polishing Stool, E. and R. Loesser, London.
8368. Melting Iron, T. Doherty and P. D. Crerar, London.
8369. Handling of Steel Balls, &c., A. L. Jenner, London.
8370. Wrenches, R. O. R. Russell, London.
8371. Card Setting Machines, J. Thornton, London.
8372. Syphon Bottles, H. W. Handcock, London.
8373. Oil Engines, J. E. W. Chadborne, Cheltenham.
8374. Hypodermic Syringe, J. Coleman, London.
8375. Cutting Bar Soap, H. E. Downs, London.
8376. Printing, F. C. Taylor and J. Cooke, London.
8377. Relays, F. E Chapman, London.
8378. Brake Mechanism, H. H. Lake.—(*C. O. Baird, United States.*)
8379. Sewing Machines, F. H. Richards, London.
8380. Telegraph Instruments, B. F. Merritt and J. M. Joy, London.
8381. Rotary Web Printing Machines, F. Meisel, London.
8382. Electric Tramcars, J. Devonshire.—(*W. B. Potter, United States.*)
8383. Boot Cleaning Appliances, &c., T. G. Benton, London.
8384. Combustible Gases, B. H. Thwaite, London.
8385. Metallic Bedsteads, S. J. Hoadly, London.
8386. Reducing Hard Substances, &c., A. Jordan, London.
8387. Stop Valves, D. B. Morison, London.
8388. Cycles, A. H. Mackmurdo, London.
8389. Packing Goods, H. A. T. Sandon, London.
8390. Photography, C. L. A. Brasseur and S. P. Sampolo, London.
8391. Pianofortes, R. M. Squire, London.
8392. Washing Clothes, J. R. Orrell, Liverpool.
8393. Casks, G. R. Lund, Liverpool.
8394. Photography, J. M. Davidson, London.
8395. Mats for Vehicles, T. Nurse, London.
8396. Clamp for Manuscripts, &c., R. Toepper, London.
8397. Electrical Resistances, H. Edmunds, London.
8398. Electrical Resistances, H. Edmunds, London.
8399. Electrical Circuits, H. Edmunds, London.
8400. Door Closing Devices, J. Cuggia, London.
8401. Knitting Machines, W. Moore, London.
8402. Preparation of Peat for Fuel, C. D. Jenkins, London,
8403. Cycles, P. S. Phillips, London.
8404. Skirt Dancing, M. M. Dessau, London.
8405. Shutters, Sheaths, Slides, &c., M. M. Dessau, London.
8406. Mechanisms for Transmitting Power, C. C. Leclaire, London.
8407. Fumigators, W. Leigh, London.
8408. Rifle, T. R. R. Ashton, London.
8409. Pumps for Pneumatic Tires, A. Clarkson, London.
8410. Electro-deposition of Metals, J. C. Graham, London.
8411. Umbrellas or Sunshades, &c., S. D. S. Ross, London.
8412. Adjusting Gearing Chains, W. C. Barns and C. O. Hillsdon, London.
8413. Construction of Boats, H. A. House and R. R. Symon, London.
8414. Necktie Holder, T. H. Biggs, London.
8415. Ties for Fastening the Ends of Bands, J. H. Huntington, London.
8416. Presses, C. T. Packer and G. W. Swift, jun., London.
8417. Machines for Polishing Tubes, P. Medart, London.
8418. Projection of Photographs of Subjects, J. Bonn, London.
8419. Hot Air and Oil Engines, R. J. Eke, London.
8420. Plush Fabrics, H. Müllers and A. Spindler, London.
8421. Means for Inflating Pneumatic Tires, O. Jones, London.
8422. Umbrellas, R. Waples, jun., London.
8423. Artificial Limbs, S. M. Kellum, London.
8424. Baskets for Transporting Fruit, T. R. Ogier, London.
8425. Tip Holders for Umbrellas, &c., H. Scudder London.
8426. Stopping Engines or Machines, T. W. R. McCallum, London.

22nd April, 1896.

8427. Coverings for Roofs, &c., H. Piquet and A. H. Griffith, Port Talbot, Glam.
8428. Electric Switch, J. B. Verity, Birmingham.
8429. Attaching Ornaments to the Hair, J. Carlu, London.
8430. Knife Cleaners, W. T. Kirkman and H. Doughty, Liverpool.
8431. Construction of Safes, J. Green, Stockport.
8432. Removing Bark from Willows, W. Bridgewater, Leicester.
8433. The "Ouse" Pike Gag, B. R. Bambridge, Eton.
8434. Ring Spinning Machines, W. Lee, Manchester.
8435. Apparatus for Cutting Fustians, J. Wilkinson, Manchester.
8436. Flat Whitewash Brush, T. J. Pickford, Bradford.
8437. Tires for Cycles, G. P. Appleyard, Halifax.
8438. Mechanical Toys, R. Bradshaw, R. Cort, and J. Whewell, Halifax.
8439. Dress Holders, H. P. Lavender, Walsall.
8440. Fraud Protection Cheque, F. Dunsford, Leeds.
8441. Mounting Pens for Ruling Machines, J. Joly, Dublin.
8442. Carpet Fastenings, W. T. Mealley, Dublin.
8443. Inking Ribbons for Typewriters, J. E. Booth, Bradford.
8444. Grilling and Boiling Apparatus, W. E. Jaques, Ironbridge.
8445. Bogie Frame, G. R. Goughins, Virginia, United States.
8446. Potato Planters, J. Tweedle, Liverpool.
8447. Steam Engines, A. Blechynden, Liverpool.
8448. Condensing Steam, Sir W. H. Bailey, A. J. Bailey, and T. Westerby, Manchester.
8449. Cycles, W. Walton, Bradford.
8450. Wind Organs, J. B. Howard.—(*L. Müller, Germany.*)
8451. Shirts, A. E. Price, Manchester.
8452. Skates, A. H. Boultbee, Sheffield.
8453. Paper Knife, A. Mahn, Glasgow.
8454. Ocean Coaling Apparatus, T. Knowles, jun., Sunderland.
8455. Jointing Drain and Sewer Pipes, W. Pilkington, Cromer.
8456. Cycle Handles, H. B. Chapman, London.
8457. Optical Toy, C. E. Gyngell, London.
8458. Electrical Recording Instruments, W. Turvey, London.
8459. Sleeve Link, M. A. Young, London.
8460. Transmitting Power or Motion, G. Greaves, London.
8461. Cycle Pedals, H. S. Halford, London.
8462. Roasting Jill, L. E. Jones, London.
8463. Time-checking Apparatus, L. T. Darnault, L. Calderon, and R. Zevallos, London.
8464. Treating Paper, H. J. Rogers and W. M. Mordey, Watford.
8465. Fog Signal Apparatus, L. T. Darnault, L. Calderon, and R. Zevallos, London.
8466. Tires, A. J. Henderson, London.
8467. Tires for Cycles, F. W. Golby.—(*B. Fröhlich, Germany.*)
8468. Locomotive Advertising Devices, F. J. Measures, London.
8469. Accumulators, W. Wilkinson, H. Alexander, and G. P. Wallis, London.
8470. Game to be Played on Lawns, M. C. N. Vowler, London.
8471. Hydrometers, A. E. Dean, London.
8472. Screw Nail, H. H. Jay, London.
8473. Fastenings for Postal Envelopes, G. Bell, London.
8474. Fire Alarm, W. Cooke, London.
8475. Keys, A. W. Lugg, London.
8476. Overshoes, S. Allsop, London.
8477. Covers for Pneumatic Tires, H. W. Stannard, London.
8478. Reducing Valves, E. Morton and G. Edwards, London.
8479. Boot Lace Fasteners, J. J. Rayner, London.
8480. Shirt Studs, H. A. Davis, Bromley.
8481. Tube Ventilator for Shops, J. Burt, Roath, Cardiff.
8482. Machine for Straining Paper-stuff, H. Schaaf, London.
8483. Electric Cable Joints, Siemens Brothers and Co. and W. Dieselhorst, London.
8484. Bending and Shaping Lead Pipes, J. W. Wilson, London.
8485. Mounting Side or Wing Mirrors, J. Porter, London.
8486. Vessel or Receptacle for Cooking, J. Westaway, London.
8487. Cooking and Grilling Meat, &c., J. Westaway, London.
8488. Supporting a Cooking Vessel over Lamps, J. Westaway, London.
8489. Filters, J. Westaway, London.
8490. Securing Watches to Cycles, E. G. Tuteur, London.
8491. Washing, &c., Spun Fibres and Stuffs, B. Thies, Cologne.
8492. Raising Door Portiere Rod Curtains, J. Lilly, Birmingham.
8493. Baby Corral, A. Wood, London.
8494. Pipes, P. F. Campbell, London.
8495. Puzzles, G. J. C. Adami, London.
8496. Supports for Scaffolds, H. Schubert, London.
8497. Construction of Buildings, J. T. Wilson, London.
8498. Money Holder, E. Rein, London.
8499. Engine Glands, J. Appleton and W. Cundliffe, Liverpool.
8500. Frame or Holder for Placards, T. H. J. Pryce, London.
8501. Circular Cutters, Sir C. H. A. F. L. Ross, Bart., London.
8502. Gasholders, &c., F. Livesey and W. T. Sugg, London.
8503. Furnace Injectors, F. Pauwels, London.
8504. Transferring Barges, &c., B. J. Thomas, J. J. Taylor, and G. C. Thomas, London.

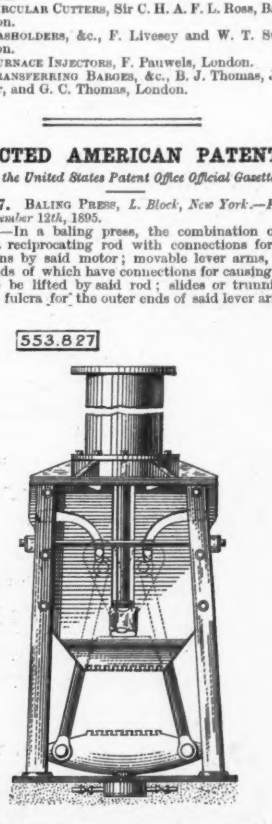
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

553,827. Baling Press, *L. Block, New York.—Filed September 12th*, 1895.

Claim.—In a baling press, the combination of a motor, a reciprocating rod with connections for its actuations by said motor; movable lever arms, the inner ends of which have connections for causing the same to be lifted by said rod; slides or trunnions forming fulcra for the outer ends of said lever arms; rising stationary ways or cam surfaces over which said fulcra may be moved as said lever arms are lifted; pitmen the upper ends of which are pivoted to said lever arms inside of the fulcra, a movable platen to which the lower ends of said pitmen are pivoted, and a stationary platen, whereby a bale may be compressed between the platens, the lifting movement of said lever arms continued beyond their horizontal position, and the strain upon the stationary parts of the press transferred on different points thereof as the fulcra are moved.

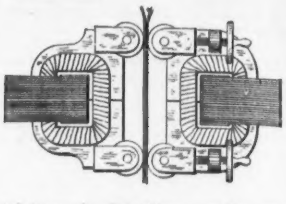
553.827



553,923. Apparatus for Electric Welding, *H. Lemp, Lynn, Mass.—Filed June 17th*, 1891.

aim.—In an electric metal working apparatus, the bination substantially as described with two transformers supplying heating currents to the same work, of alternating current sources connected respectively to the primaries of said transformers, and adapted to supply alternating currents of different frequency.

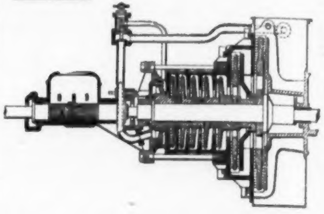
553.923



553,932. Steam Turbine, *C. A. Parsons, Newcastle-upon-Tyne, England.—Filed February 21st*, 1895.

Claim.—(1) In combination, the propeller shaft, the dummy piston thereon, the turbine wheels or discs, the steam supply pipe leading to the dummy piston to resist the end thrust, and a valve controlling said steam supply automatically, and means for controlling said valve in proportion to the end thrust, substantially as described. (2) In combination, the propeller shaft, a bearing therefor to allow end thrust of the same, a dummy piston on the shaft, a steam supply leading to the dummy piston, a valve controlling said supply, and means controlling said valve in proportion to the end thrust, substantially as described. (3) In combination, the shaft, the turbine thereon having the dummy piston, and the fluid supply leading thereto, whereby said dummy piston will balance the end thrust, substantially as described. (4) In combination, the shaft, and turbine thereon arranged to take up the end thrust, the inlet for the steam to the turbine, a second inlet for the balancing fluid, a valve controlling the said inlet, a piston controlling the operation of the valve, and a connection from the piston chamber to the first steam inlet leading to the turbine, whereby the balancing power of the fluid will be proportional to the fluid pressure from which the rotation is derived.

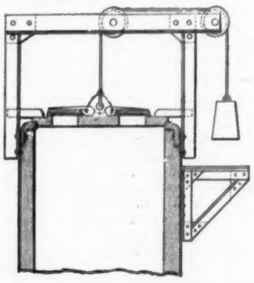
553.932



553,956. Explosive Valve for Blast Furnaces, *T. Coultas, Pittsburg, Pa.—Filed April 4th*, 1895.

Claim.—In explosion valves for blast furnaces, the combination with the down-take pipe, of a vertical pipe leading from the upper end of said downtake, a valve at the upper end of said pipe, rods passing through said valve and through projections on said pipe, springs interposed between said projections and shoulders on said rods, a frame supported by said pipe, a rope secured to said valve and passing up over a pulley in said frame, a second pulley over which said rope passes, a weight at the end of said rope, and a shelf secured to said pipe and adapted to support said weight when lowered, substantially as set forth.

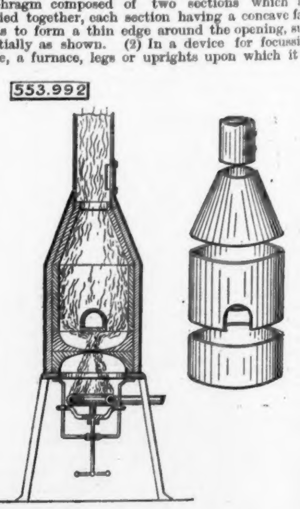
553.956



553,992. Apparatus for Focussing Flame, *C. H. Land, Detroit, Mich.—Filed January 15th*, 1894.

Claim.—(1) In an apparatus for focussing flame, a diaphragm composed of two sections which are applied together, each section having a concave face so as to form a thin edge around the opening, substantially as shown. (2) In a device for focussing flame, a furnace, legs or uprights upon which it is supported, U-shaped supporting arms, having a threaded opening through its lower end, an adjusting screw which passes up through the arms, and a spider which is vertically adjustable upon the arms and forms a support for the burner, combined with a Bunsen burner, and a thin-edged diaphragm at the bottom of the furnace, substantially as specified.

553.992



WAGES IN THE ENGINEERING TRADE.

By J. STAFFORD RANSOME.

II.—TRADE UNION INFLUENCES.

MY first article of this series dealt with the great inequality of wages in different districts, and two schedules were used for the purpose of showing that the standard of wages in a given town was by no means necessarily proportionate either to the size of the town, or to the strength of the local trade union element in it. With regard to the first of the above points, no argument or amplification is necessary; as, by means of the local census returns on the one hand, and, on the other, the statistics as to the wages paid, anyone interested in the question can satisfy himself without difficulty as to how far the wages standard has to do with the population of a town.

A comparison, however, between local standards of wages and the amount of local trade union influence is a more complicated matter, for the following reasons:—(1) The number of men returned as belonging to trade unions is invariably exaggerated. (2) An accurate return, giving the total number of men in a trade—that is to say, the men who might be qualified to join the unions—does not exist in most localities. (3) The strength of the trade union influence cannot always be gauged by the number of trade union members; as it frequently happens that, when there are several unions in one trade, their tactics are so diametrically opposed that, instead of strengthening each other, they very materially weaken the influence of trade unionism generally.

I think it well to repeat here a portion of one of the schedules given in my last article for the purpose of comparing local trade union influence with local rates of wages in some of our large engineering centres.

Table showing Towns in their order of Wages and Trade Union Influence.

Rate of wages.	Position.	Trade Union influence.
London	Highest ...	Belfast
Sheffield	2nd	Sunderland
Manchester	3rd	Bolton
Birmingham	4th	Newcastle-on-Tyne
Liverpool (with Birkenhead)...	5th	Leeds
Bolton	6th	Glasgow
Belfast	7th	Dundee
Bradford	8th	Bradford
Newcastle on-Tyne ...	9th	Manchester
Sunderland	10th	Liverpool (with Birkenhead)
Glasgow	11th	Sheffield
Leeds	12th	Birmingham
Dundee	Lowest... ...	London

From this table it is clear that, as far as the engineering trade is concerned, local trade union influence has but little to do with the wages paid locally. This may come as a surprise and even as a shock to those people who habitually credit the trade unions with having forced wages up to their present height, but unprejudiced students of trade union principles have long since known that these societies, as at present worked, cannot have any solid influence of a permanent character in forcing up the rates of wages. One may go beyond this, and state that to force up wages is dead against the interests of present-day trade unionism, and its policy is merely to maintain a rate of pay below which scale the most inferior hands in the trade must not accept work, and for more than which the best and most skilled men are not allowed to ask. To put it in other words, it should be distinctly understood that the line adopted by trade unionism is not to raise the pay of men in accordance with their merits, but to force up the price of the inferior men as high as possible, and then drag down the better men to that level. People generally ignore the fact that the trade unions resent masters paying a higher wage than that prescribed by the union rate, and that over and over again the unions have done their best to pull down the wages in shops working under these conditions.

This is quite a rational policy from the point of view of the men who run these societies, and make their living out of them. For in order to make trade unionism pay them, the first thing to do is to establish a hold on the men, so that they may be able to force them to pay their subscriptions. This, of course, they are unable to do unless they can oblige the good workmen to accept the same wages as the dregs of the trade.

Two of the chief influences which tend to weaken trade union power are brought about, firstly, by the existence of *bonâ fide* benefit clubs, either organised by the men themselves, or between masters and men, and which give benefits four or five times as great as those promised by the unions for a similar expenditure. The effect of such institutions is to make the men to a great extent independent of the trade societies. The second weakening influence comes into force when the better men realise that they can do more for themselves in the way of wages outside the union than in it.

Apropos of this question, it is as well to remark that ignorant people still imagine that workmen in non-unionist factories are paid less than those in "society shops." A greater fallacy never existed, at all events in the engineering trade. In a general way the non-unionist is at least as well paid as the unionist, and often his wages are higher. In any case, when the pay is equal, the net amount of weekly money accruing to the non-unionist is higher than that of the unionist, as his wages are not "sweated" by any trade society. No doubt the trade unionist rejoinder to the above will be, that the unionists have fought the battles and raised wages to their present standard, and that then the non-unionists have sneaked in, and, without paying anything to the societies, are now able on their own account to insist on the union rate. This is all plausible enough, and would be a very strong argument in favour of trade unionism were it true, but it is not; for, although the trade unions are continually fighting battles, ostensibly for the benefit of labour, the particulars in the schedules I have given prove, at all events, that if trade union influence has made wages what they are, they have signally failed to run up the rates of pay in their strong centres. In fact, when the *modus operandi* of trade unionism is understood, it is no difficult matter to appreciate that its influence cannot possibly materially affect the pay sheet in the long run.

What trade unionism can do, and what it very frequently does, is to force wages up in a certain locality by dint of bringing to bear on that one spot, for the time being, all its machinery and organisation. But if the wages thus forced up reach an unduly high figure, one of two things must happen; either the wages sink back to their natural level directly the undue pressure is withdrawn, in which case the rise of wages is not of a permanent character, or the unduly high rate is maintained; but the work leaves the locality, and goes to another where the wages are lower, or other conditions more favourable. Thus, in a given locality, wages may be forced up by a trade society to an entirely unjustifiable extent; and, by dint of great expenditure of trade union funds, they may be maintained at that level. But the work cannot be retained, and naturally goes elsewhere. Consequently it matters little how high the rate of pay is fixed when no work is forthcoming at the price.

There are innumerable instances of the above, and London has been more often attacked in this way than any other centre. Two striking cases in point are afforded by the Coopers' Union and the Compositors' Union. The former, by dint of squandering large sums of money, has managed to maintain so high a rate of wages that the manufacture of tight casks by hand has practically been stamped out in the metropolis. The Compositors' Union has, by similar methods, driven all the printing that can possibly be done elsewhere, out of London, and much of it out of the country. On the strength of these facts, it might be argued that, after all, if the unions can bring about such a state of things, they must be capable of raising wages on their own initiative. But, as a matter of fact, they do not effect a general rise all round; for while they are using undue pressure to bring about an abnormal rate in one locality, they have to neglect all the others; and, without doubt, it is usually the districts so neglected which profit in the long run by getting the extra work.

Speaking generally, the most serious effect of trade unionism on the wages question is a disastrous one, for the unions can and do use their influence to lower the quality and quantity of the work done for a given rate of wage in a given time; for the trade union standard is based on the capacity of the inferior workmen, whom it is the business of the union to protect from competition by not allowing the better men to receive higher wages. Thus the unions, while not able unduly to lift wages all round, can, by the methods of their organisation, give an employer a minimum of quality and quantity of work for a certain fixed wage. This is very accentuated in the engineering trade, and goes far to account for the preference which masters often have for a non-unionist, even at a higher price.

It is not a very long time since masters in the engineering trade were under the impression that practically all their skilled hands belonged to one or another of the trade societies. That such, however, is not the case, is clear from the fact that in the most union-ridden town in the trade, Belfast, at least 20 per cent. are non-unionists. In Glasgow the non-unionists number at least 60 per cent., and in London about 75 per cent. I do not pretend to have anything but a vague idea as to the proportion of unionists to non-unionists throughout the engineering trade, but, taking the unskilled element into consideration, I have no reason to suppose that the unionist element is greatly stronger in engineering works than the union average in all the trades of the country, viz., about one-seventh of the men employed. A return of engineering unionist members would probably show on paper a considerably higher proportion than this, but as certainly half the number enrolled do not pay their subscriptions with any regularity, they cannot be said to really belong to the unions, as they have forfeited all rights to any of their "benefits."

Wages in the engineering trade are "sweated" by a considerable number of trade societies, of which the largest is the Amalgamated Society of Engineers, which professes to have over 75,000 members, of which somewhat less than 65,000 are supposed to be "paying" members, the balance presumably being made up of paid officials. This society, though, financially speaking, thoroughly rotten, has always been considered the most powerful trade society in the world. This is mainly due to the fact that its politics have all along been of the aggressive order, and no doubt it has spent more money on strikes than any other trade union, though its big strikes have nearly always resulted in disaster to its members.

The society which is second in importance in the trade is that of the boilermakers and iron shipbuilders, familiarly known as the "black squad." The membership of this society is said to be considerably more than half that of the Amalgamated Society of Engineers, but, in that it covers only a section of the trade, it is a far more representative union of that particular section than the other is of the whole trade. It is also much more financially sound, and less aggressive in its policy. Then, again, it usually does a great deal better for its men than does the Amalgamated Society of Engineers. This is due to the fact that its policy is always to settle its differences without resorting to strikes if possible. The Amalgamated Society, however, whose paying members really have no voice whatever in its management, is credited with bringing about labour disputes on frivolous pretexts, and it is no secret that some of its biggest strikes have been organised for the purpose of advertising a certain agitator, or of drawing attention away from unpleasant matters connected with the internal working of its organisation.

A forcible instance of the slight effect of trade unionism on the wages question was afforded in the engineering trade by the recent Clyde and Belfast disputes. The papers persisted in referring to these strikes as a "Shipbuilding dispute." But, as a matter of fact, the shipbuilding element, as represented by the "Black Squad," came to terms with the masters in both localities before the strike began. For personal motives, however, the Amalgamated Society of Engineers found it policy to make their men strike, ostensibly to get better terms than those obtained by the shipbuilders. But after a protracted struggle, and expending vast sums of money on a futile dispute, the engineers accepted practically the same terms as those accorded to the shipbuilders, and originally offered to them. This points strongly to the fact that aggressive trade unionism cannot do more than reasonable trade unionism in the way of lifting wages.

Then comes the question as to what reasonable trade unionism can effect. As a matter of fact, the reasonable element is nearly always swamped by the aggressive element at the present day, and so the public are unaware that there are still a few trade societies which conscientiously study the interests of their men. Such societies can, by carefully watching the ups and downs of trade, determine the best moment at which to demand a rise; they can then firmly put their demand before the masters; not in an exaggerated form, but merely asking for what they consider they are entitled to. Then, if their demand is a reasonable one, and the masters are made aware that they are prepared to bring the whole of their strength to enforce it, they may perhaps get their rise a few months, or even a year earlier than it would come in the ordinary course, or at all events with less trouble. This is the utmost an ideal trade union can be expected to do in the way of permanently raising wages. In a similar manner a reduction of wages may be successfully resisted for a time.

I do not believe that an ideal trade union, worked on impossibly conscientious and intelligent lines, could generally and permanently influence the rate of wages to any great extent—to an extent, let us say, which would cover the ordinary weekly subscription paid per man to keep the union going. The usual argument about wages having gone up since trade unionism became the order of the day is, of course, fostered by trade union leaders for obvious reasons. But wages have risen since the Salvation Army was started, and since the Tay Bridge was blown down; though no one in his senses attributes this increase to either of these causes. Nor is it due to the influences, good or bad, of trade unionism; for wages have risen in localities where there is no trade unionism, and they had begun to rise long before there was such a thing as a trade society, and will go on rising as long as civilisation advances, even if the trade unions were to be swept off the face of the earth. Money does not go as far now as it did years ago. It is all very well to say that in some cases the necessaries of life are cheaper than formerly, and others quite as cheap; but at the present day a man's necessities are vastly more numerous than they were, and as civilisation and education increase, so will the wants of the working man increase, and his wages will in the natural course of things follow his wants. Bad times will no doubt, as in the past, check an increase in his wages from time to time, whether trade unions endeavour to force matters or not. But it is reasonable to suppose that in the long run wages must be in the ascendant.

People generally have got into the habit of considering that the trade unions have been instrumental in raising wages, because they hear every now and then that such and such a trade society has called its men out on strike for more money, and sometimes it appears to have been successful in getting it. But what does a successful strike as carried out by a trade union mean? Take the two great "labour victories" of modern times, the Dock Strike of 1889, and the Coal War of a couple of years ago. In the first, which had for object the raising of the pay of the "casual docker" from 5d. to 6d. per hour, the extra money was enforced, but the casual docker was ousted from his trade by a better class of man who came to compete with him, and by the labour-saving appliances which the dock company has found it advisable to lay down now that the price of labour has risen.

The effect of the "successful" Coal War was to break up innumerable homes, permanently to ruin property which habitually found work for thousands of men, and to allow the masters to dispose of their stocks, and pit-mouth rubbish, at famine prices; after which, owing to the temporary increase in the price of coal, they were well able to afford for a time to pay the higher wages demanded. At the present date the wages in that industry are regulated by a committee, and follow the ups and downs of the state of trade.

Trade unions are bound to appear to make a great fuss about the wages question, as one of their most popular war cries is "more money," which naturally catches on with the men. Trade union influence can distort and temporarily modify the rates of wages, but it cannot of itself effect a real all-round increase, nor can I find any perceptible trace of its being responsible for the want of equalisation in engineeering wages which exists in different parts of the country.

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE spring meeting of the Institution of Mechanical Engineers commenced on Wednesday, the 29th ult., and was held at the premises of the Institution of Civil Engineers, Great George-street, Westminster. After the customary formal business had been disposed of, the President, Mr. E. Windsor Richards, read his address, in which he gave an outline of the conditions governing the production of raw materials for engineers in a cheap and effective manner. As this is given *in extenso* on another page, we shall not attempt to deal with it any further here.

Mr. Laird, in proposing a vote of thanks to the President, congratulated him, and enumerated instances in which English inventions, such as the rolling mill, the Bessemer processes, &c., had been adopted by continental firms, which showed that we were not alone in the race of industrial progress as regards the production of iron and steel, and that English manufacturers must look to their laurels. The vote of thanks was seconded by Mr. Jeremiah Head, who, in the course of his remarks, said that he thought English firms would be well advised if they followed the example of Mr. Carnegie, who sends two of his managers annually on a visit to Europe, with salaries and expenses paid, in order to see what was going on and take note of valuable developments. Mr. Head also pointed out that two very important industries, those of watch-making and sewing machine making, had almost entirely left our shores for those of America, which had outstripped us in the matter of cheap production.

The discussion of the paper on "Notes on Steam Superheating," read by Mr. W. H. Patchell before this Institution on January 31st last, and which was reproduced in full in The Engineer of February 21st—see page 196—was then proceeded with. Mr. Patchell, however, first made a few additional remarks. He said that Messrs. J. Musgrave and Sons, Bolton, had written to him stating that the superheater—Figs. 4 and 4A—attributed in the paper to Messrs. Hick, Hargreaves, and Co., had been made by them, and a patent had been taken out in the names of Musgrave and Dickson. Speaking of the evaporative efficiency of the Babcock and Wilcox boilers, mentioned in the paper, the author said there was nothing remarkable in this performance, which was only about the average obtainable from other boilers.

Mr. Edward Perrett next described an arrangement of engine and boiler for utilising superheated steam, which he had experimented with for a long period some years ago. The entire plant comprised a boiler, a regenerative furnace, and two separate steam cylinders, high and low-pressure. The steam, after having done duty on one side of the high-pressure piston, was returned into the regenerative fire-brick furnace, where it was superheated and then admitted to the other side of the said piston, from which again it was exhausted into a low-pressure cylinder. It is rather difficult to describe the arrangement without a diagram, and we hope to be able to place an illustration of this interesting early attempt at superheating before our readers in a future impression.

Professor W. C. Unwin said that the reason superheated steam had not become more generally used in this country was, that engineers did not understand its *rationale*. There were three ways of using steam in an engine—First, the ordinary wet boiler steam; secondly, the moderately superheated steam, which was wet in the cylinder; and thirdly, there was the highly superheated steam, which was superheated as used in the cylinder. As far as he knew, Herr Schmidt was the only person at present using the last named, but he was not yet in a position to state whether it would prove a success commercially. He wished to emphasise the fact that the addition of a superheater to an installation was an engine gain, and not a boiler gain, being of the same nature as the steam jacket. Professor Unwin then went into the history of superheating, and said it was not taken up in this country till 1859, but the practical value of superheated steam was really first discovered by Hirn in 1855. Going on to criticise the paper, the speaker said that the boiler and engine economies were mixed up, and there was not enough information to show which advantages were and which were not due to superheating. Referring to the McPhail and Simpson apparatus, Professor Unwin said that if it were a superheater at all it was so by accident and not design, and was of opinion that it would disappear in favour of the arrangement used by Hirn, in Alsace. He had tested a 500-horse power engine working with this arrangement for two years, and did not find the necessity of a special device for regulating the temperature of the steam. The great secret was in putting the superheater in the proper place. With superheaters placed near the furnace a smaller area is required. Speaking generally, a gain of 15 to 20 per cent. with ordinary engines would be effected by adding a superheater to a boiler, with a proportionate gain in the consumption of fuel.

Mr. Phillips, the next speaker, said he had been engineer on a steamship in 1851, on which a superheater was provided, though not used, but steam superheating had been employed in the Navy before this date. He thought the credit for its introduction should be given to the American, Wetherhed.

Mr. Bryan Donkin confirmed Prof. Unwin's remarks regarding the regulation of the degree of superheating. He said the answer to the question, Why is superheated steam more economical than saturated steam? was obviously that cylinder condensation is reduced owing to the temperature of the cylinder walls being raised; but he had found that the temperature of the cylinder might be raised by superheated steam, and the steam be saturated prior to the movement of the piston.

The proceedings were resumed on Friday evening last, when the further discussion of Mr. Patchell's paper was continued. Mr. M'Phail was the first speaker, and read what was practically a paper expounding the advantages of the M'Phail and Simpson's superheaters, which is too long for reproduction in our columns. Mr. Lavington E. Fletcher next gave a few figures from tables relating to tests made by the Manchester Steam Users' Association of superheaters. These tables were handed in to the secretary for insertion in the statistics of the society. Mr. Jeremiah Head gave some further particulars of the superheating engine with regenerative furnace, which Mr. Perrett alluded to in Wednesday's proceedings.

After a vote of thanks had been accorded to the author, the President called upon the secretary to read a paper on

Steel Steam Pipes and Fittings and Benardo's Arc Welding in connection therewith,

by Mr. Samuel MacCarthy, of which the following is an abstract:—

Cast iron and copper pipes.—Cast iron, which has the advantage of being seamless, and which can be moulded into any desired shape, is heavy, cumbrous, frequently porous, and always liable to fracture by a blow. The necessarily great thickness of cast iron steam pipes, and the rigidity of the bends, also add greatly to the difficulties of arranging for expansion. Hence the use of this material, for pressures over 50 lb. or 60 lb. per square inch, is becoming more and more rare. Copper, which for so long a period was almost exclusively adopted in the Navy, and also to a great extent in the mercantile marine, for steam and feed pipes, has, in consequence of numerous disastrous failures, become of late years greatly discredited. The causes of its failure need not be entered into here, inasmuch as the subject was fully dealt with in the paper on steam pipes, which was read by Mr. J. T. Milton before the Institution of Naval Architects in April, 1895—"Transactions," vol. xxxvi., page 191.

Wrought iron and steel pipes.—Cast iron and copper having failed to afford the necessary security and confidence in connection with steam at high pressures, there arose a great demand for welded wrought iron or steel pipes, which was promptly met by the leading tube makers, who lost no time in procuring the requisite machinery for their manufacture. With regard to the respective merits of iron and steel for this purpose, as for many others, there has always been a difference of opinion among engineers; and the controversy is not yet at an end, but invites renewed experiment and useful discussion.

Corrosion.—One of the principal objections raised by the opponents of steel has been that it is more subject to corrosion than iron; and doubtless this would be a grave defect if shown by experience to prevail. This matter was dealt with at great length in the paper on the comparative endurance of iron and mild steel when exposed to corrosive influences, which was read by Mr. David Phillips before the Institution of Civil Engineers in March, 1881—"Proceedings," vol. lxv., page 73. As the result of numerous experiments, he came to the conclusion that steel, in the form either of boiler tubes or of plates, was greatly inferior to iron in power to resist corrosion; but in the lengthened discussion which followed, the speakers were almost unanimous in their dissent from this conclusion. At all events, whatever may be the result as regards boiler tubes, there is every reason to believe that welded steel steam pipes are free from any risk in this respect. Recently the author has had an opportunity of examining several lengths of 7in. steam pipes and bends, made of steel, at the City of London electric lighting station at Bankside, which have been constantly at work at a pressure of 160 lb. for over three years, and which exhibit not the slightest appearance of pitting, scoring, or corrosion in any form. In erecting ranges of steam pipes great care should be taken to ensure efficient drainage; for should there be any point in the range where the condensed water is allowed to lodge, corrosion will no doubt take place sooner or later at that part, whether the pipes are made of wrought iron or of steel.

Thickness of metal.—As to the comparative thickness of steel and iron pipes, it might naturally be expected that the former would be made lighter in proportion to the greater tensile strength of steel. Theoretically this should be so; but in practice it is carried out to only a limited extent. Not only is a large margin required for safety, but the exigencies of manufacture necessitate a certain thickness of plate to ensure making a sound weld; and this thickness cannot be reduced without risk. For instance, a common size of steam pipe, 10in. bore, is most conveniently made of ¼in. plate, which would be amply strong enough for iron, and is consequently excessive for steel; but the reduction of $\frac{1}{16}$in. in the thickness would affect the cost and the weight so slightly that it is thought best to err on the safe side. For larger sizes, of 12in to 18in. bore, it is found practicable to make steel pipes somewhat lighter in proportion to iron. In this connection it is interesting to note that the Admiralty are now using steel for all sizes of steam pipes over 2in. bore. Above 9in. bore they still adhere to the practice of having a butt strap or cover strip riveted along the line of weld, which the author believes to be worse than useless, as the numerous rivet holes necessarily tend to weaken the pipe. It is also probable that the presence of the cover strip, in connection with the expansion of the pipe both circumferentially and longitudinally, has the effect of setting up a tearing strain, which may result in leakage at the rivets. The addition of the butt strap also adds greatly to the cost of the pipes. In a recent specification for steam pipes the Admiralty fix three-eighths of an inch as the uniform thickness for all pipes from 6in. to 14in. diameter of bore, the tensile strength of the steel not to exceed 25 tons, and not to be less than 23 tons per square inch. In the following Table I. are given the thicknesses which are usually specified for steam pipes from 6in. up to 18in. bore, for pressures varying from 100 lb. to 180 lb. per square inch; also the corresponding hydraulic test pressures. In addition to the hydraulic test, the pipes are also tested with high-pressure steam. This is important, because they are thus tested under actual working conditions as regards temperature and consequent expansion; and any minute pin hole which has not been revealed by the cold water test is certain to be detected under steam.

Table I.

Thicknesses of Steel Steam Pipes for Varying Pressures.

Methods of manufacture.—It is frequently supposed that the electric arc is brought into operation for welding the longitudinal seam of the barrel of the pipe. As a matter of fact this is not the case. It can of course be done, and has been done successfully in many instances; but as it was found from experience that no saving in cost was effected, and that nothing was gained either in speed or in efficiency by the use of electricity for this purpose, the straight seams are still welded in the ordinary manner: namely, either in the rolls, or by gas and power.

Roll welding.—In this process the iron or steel in the shape of strip is first scarfed along both edges in a planing machine, on the outer face along one edge and on the inner face along the other; it is then heated in a muffle, and by being drawn through skelping dies is bent into tubular form or skelp, and is ready for the welding furnace. When the welding heat is reached, the skelp is withdrawn from the furnace with tongs, and the end is placed upon the head of a horizontal mandril fixed to a long rod, which is held between a pair of revolving rolls that are turned to suit the particular size of tube being made. The skelp being seized by the rolls is rapidly welded by the pressure exerted upon it between the two rolls on the outside and the mandril on the inside of the tube. In all cases the tube is drawn twice through the rolls at a welding heat, the process being the same each time. On finally leaving the welding rolls, the tube passes through a mangle or reeling machine, which straightens it; the ends are then cut off square, and it is ready for testing.

Gas welding.—The strips, after being scarfed along their edges, are heated only cherry red in a muffle, and are then bent to the required diameter in the rolls. The pipe is next placed on a "beak," and a jet of gas is brought to bear along the seam, whereby in a short time a length of about 6in. to 8in. is brought to a welding heat. A small quick-speed steam hammer fixed above the work then rapidly closes the seam, and completes the weld. The operation is repeated on the next length, until the longitudinal seam is completed. The use of gas renders the process clean, and absolutely free from dust and other impurities; and the edges of the pipes having been carefully freed from scale after leaving the heating furnace and rolls, a perfectly sound weld is obtained.

Benardos arc welding.—It is in the manufacture and attachment of flanges, branches, bends, and tee pieces, that the Benardos system of welding by means of the electric arc plays such an important part. This process has now been in constant operation for over five years at Messrs. Lloyd and Lloyd's Coombs Wood Works, near Halesowen, with which the author is connected, where during this period it has been employed chiefly on large steel pipes and connections, suitable for high-pressure steam. The method of working is simple. Ordinary low-tension continuous-current lighting dynamos are used; to the terminals of these a battery of Benardos accumulators is connected, into which the current flows continuously. When the welding circuit is closed, the current flows from the dynamos and accumulators; and large resistances are used when necessary. In this way a large discharge is obtained, equal to about twice the capacity of the dynamos, and the load factor of the apparatus is high. For some purposes it is possible to work without the accumulators; but when this is done the efficiency of the apparatus is not so high, because during part of the working period no current whatever is passing, and the machinery is running light. As illustrated by the diagram—Fig. 1—the plant is run on the parallel system, and between the terminals of the dynamos or battery as many welding arcs can be connected as may be desired; and every welder is able, independently of the others, to vary his own current to suit the work in hand at the moment. One terminal of the circuit is connected by means of a flexible cable to a carbon pencil in an insulated holder, which is held by the workmen; the other terminal is connected to the table on which the work lies, or to the work itself. When iron or steel is under treatment, it is usual to make the carbon the negative pole, and the iron or steel the positive pole; but for other metals the poles are sometimes reversed. [In an appendix is given a summary of the results of experiments made by Messrs. David Kirkaldy and Sons for Messrs. Lloyd and Lloyd, to ascertain the tensile strength of electric-welded bars of various brands and sizes; and also a comparison of these with fire-welded bars.]

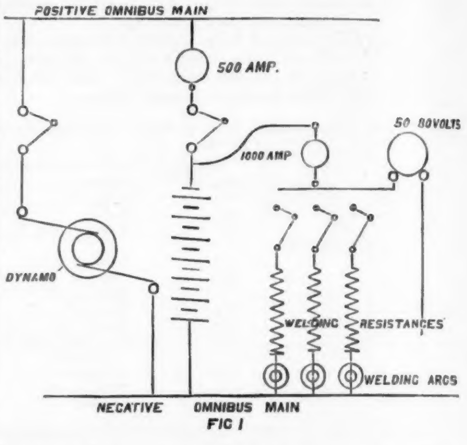

FIG I

Flanges.—The method usually adopted for welding flanges to steam pipes is as follows:—The flange is stamped out under the steam hammer in such a way that a V-shaped groove is left on the inside edge, extending about three-fourths through the thickness of the metal. The flange is next shrunk upon the tube, with its flat face outwards or at the end of the tube, and is carefully set in the exact position required. The welding consists in laying small pieces of steel in the V-shaped groove, and welding them in one by one by means of the electric arc, the welds being freely hammered between each heat. The welder makes a complete circuit of the back of the flange, and fills it up sufficiently to make a fillet of about 1½in. radius. In this way the flange is solidly welded to the tube at the back, and about three-fourths of the way through its thickness; but the front or outer side is not yet welded. The tube is then up-ended, and the outer side of the flange is welded to the tube, the only difference being that the heat of the arc is used to burn out a cavity all round the junction of the pipe and the flange, until the depth is reached at which the two have already been united; this cavity is then welded up in the same way as the back of the flange, thus ensuring that the flange is welded solid to the pipe right through.

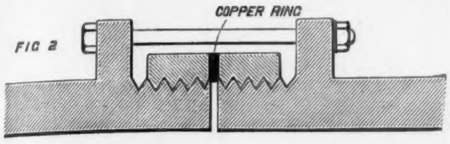
Outlets, branches, and tee pieces.—The welding of outlets and branches into steam tubes is done by much the same method as already described in the case of the flanges. The outlet, which consists of a piece of ordinary lap-welded tube, is cut off to the required length, and a hole is burnt by the arc in the tube, large enough for the outlet just to fit into. When fixed in the right position the outlet is welded in, as in the case of the flange, by laying on small pieces of steel about 1in. long by ¾in. wide and ¼in. thick, and welding them in one by one, continuing the process all round the outlet, until a fillet is formed of about 1½in. radius, but this varies slightly with the position of the outlet on the tube. A tee piece is made in a precisely similar way, a short piece of tube being welded into a longer piece; and a cross is made by welding two similar short pieces, one on either side of the main tube.

Length and size of arc.—One point in connection with electric-welded work, to which the author would call special attention, is the length and size of the arc which is used in the welding of various kinds of work. With a short arc, the carbon point is brought down too close to the steel; and the result is inferior work, not only from the presence of the carbon, but also because the heat is concentrated upon so small a surface that the strains set up in cooling are considerable. The longer the arc, the softer and more diffused is the heat; and any slight strain which may be set up can be got rid of by careful annealing. A long arc is therefore indispensable to the proper working of the system.

Strength of electric-welded flanges.—An 8in. iron pipe ¼in. thick, with flanges electrically welded on, when tested to destruction at Lloyd's Proving House, Netherton, broke in the body of the pipe at over 88 tons, the welded part remaining intact; and a similar pipe of steel broke in the welded part of the flange at over 101 tons. These tests were tensile only, and were carried out with the view of proving the absolute soundness and consequent strength of the flanges electrically welded on. For this purpose special tackle was made. A blank flange with an eye-bolt attached was secured to each flange of the pipe, and the chain of the testing machine was connected with the eye-bolts at each end, with the result given above.

Other applications of arc welding.—All kinds of work of the above description can be readily and satisfactorily done by this process; but its utility in large works does not stop here. Small flanges can be heated and welded upon tubes by spinning them in a lathe at a high speed and allowing the arc to play on them, the weld being made by the pressure of two rollers, one inside and the other outside the tube. Defects in steel castings and in finished forgings can be repaired with the greatest ease; and the fact that, when such repaired articles are faced or turned in the lathe, the turnings come away sound and whole, is a proof that the welding has been perfect, and that the metal has not been burnt or rendered brittle by the process.

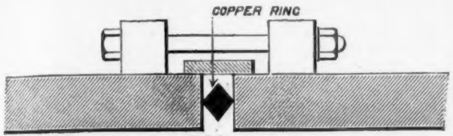
Joints.—In connection with the cognate subject of joints, the author is enabled, by the kindness of Mr. Frank Bailey, to describe a simple form of joint in use at the City of London and the Metropolitan electric lighting stations, which, in conjunction with the solid electrically welded flanges, has given excellent results. As shown in Fig. 2, the joint is made simply with a copper ring, one-eighth of an inch thick. These rings are cut of the required thickness from a copper cylinder of the necessary size, and are carefully annealed. The great thickness of the solid welded flanges admits of their being screwed tightly together, without any possibility of springing; and an absolutely steam-tight and durable joint is thereby made, which gives no trouble whatever.



FIC 2

Bolt holes.—Another great advantage of the solid welded flange is that it obviates any difficulty with the bolt holes. The frequent trouble and annoyance experienced with screwed flanges from the bolt holes not coming fair opposite each other are well known; and the objections to flanges riveted on steam pipes are too obvious to need any comment.

In the short discussion which ensued, Mr. Druitt Halpin criticised the form of steam joint shown in Fig. 2 as being open to objection on account of the screw threads being exposed to the action of the steam, and sketched on the board a form of joint shown in Fig 3.



FIC 3

In this the joint-making material is a copper ring of diamond-shaped section which is held in position by a metal ring surrounding the two ends of the piping. In fact it is the Perkins joint.

Mr. Howell, of Sheffield, objected to the Benardos method of welding, which he called soldering, owing to the effect it produced in the steel of making the metal "short." He had found that gas was better suited for welding purposes. Speaking of the corrosion of steel sometimes complained of, he said this must be due to inferior qualities of steel used, and suggested that if buyers of steel piping would leave themselves more in the hands of makers, instead of submitting ill-constructed specifications, they would be much better served,

Mr. Mark Robinson gave the results of some experiments recently made with lap-welded steel pipes to withstand endwise compression, and he had found them to behave excellently across the weld. He had compressed them to a concertina shape without fracture.

Mr. Platt said he preferred solid drawn steel pipes, which could now be obtained 12in. diameter in 12ft. lengths.

Mr. Carter considered that it was a mistaken idea to liken the electric welding process to soldering. He said that the electric current had a sort of infusive action, as proved by their being able to weld copper with steel. He asked the author if he could supply figures giving the relative cost of electric and gas welding.

Mr. MacCarthy having briefly replied, the meeting was closed with the usual votes of thanks. The report of the Research Committee experiments "On the value of the Steam Jacket: Experiments on a Locomotive Engine," by Professor T. Hudson Beare and Mr. Bryan Donkin, which was also down for reading, was adjourned till the Belfast summer meeting.

The dinner of the Institution was held at the Freemasons' Tavern, Great Queen-street, W.C., on Thursday, the 30th ult., and was largely attended. Amongst those present were the Hon. Thomas F. Bayard, Ambassador of the United States of America; Sir William Arrol, LL.D., M.P.; Sir Frederick Abel; Sir Edward Leader Williams; Sir Edward H. Carbutt; Mr. Thomas Richardson, M.P., and numerous other prominent gentlemen. The President, Mr. E. Windsor Richards, in proposing the toast of "Our Guests," coupled with it the name of the American Ambassador. In replying to the toast Mr. Bayard remarked that Archimedes, some hundred years before the Christian era, advanced the celebrated proposition that a solid body projected into liquids displaced its own equivalent weight. But even that celebrated member of the Institution of Mechanical Engineers did not tell them whether liquid projected into a solid body displaced its own weight. He was inclined to think that Archimedes had never dined with that society, and that even he would have had something to learn from modern civilisation. One of the great lessons, and perhaps the greatest, of science, as expounded by Archimedes, was the Archimedean screw, and he believed that this was nothing but a corkscrew. This, he said, was called the age of invention; London was only made possible by invention, discovery, and the application of mechanical engineering. Mechanical genius could not be circumscribed, for mankind must be the beneficiaries of the inventor and the discoverer. Mechanical engineers were the best ambassadors that could go forth into the world, for what was an ambassador if he were not the introducer and inducer of peace and goodwill, and of fair understanding between men?

Sir William Arrol, replying to the toast of the "Houses of Parliament," spoke of the unusually large number of mechanical engineers now in the Commons, but said the progress made in the business of Parliament was such as would not be tolerated in commercial undertakings. In proposing the toast of the "Institution of Mechanical Engineers," Prof. Roberts-Austen eulogised the excellent work done by this Institution in providing the means for conducting research. In acknowledging the toast, the President remarked that as the Institution was about to provide premises of its own at a cost of £23,000, they would have to economise somewhat for the next few years in the matter of research.

RESERVOIR DAMS WITH IRON SHEETING.

By Mr. Thomas Thomson.

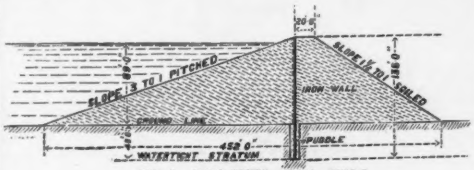
A small paragraph some weeks ago mentioned that a dam was being constructed somewhere in the States, in rather a novel manner. A wall of iron was to be employed, backed up by rock filling on either side. No further details were given, but it is evident that no strutting was to be employed, the iron simply fulfilling the duties of a water-tight sheet, and being kept in place by the filling, which supplies the necessary weight. It may be considered to all intents as an ordinary earthen dam, in which a continuous sheet of iron has been substituted for the ordinary puddle wall.

The writer has long been of opinion that a dam constructed in this way is superior in many respects to either an earthen dam with a puddle wall or one constructed of masonry. As an iron dam is now actually being built, it may be interesting to investigate the points in its favour.

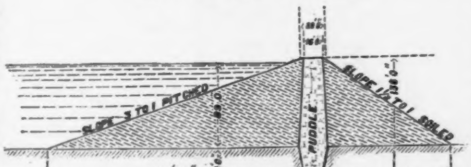
Let us see first the conditions which must be satisfied in a dam of any construction.

(1) It must have sufficient mass in each unit of its length to prevent rupture, overturning, or sliding on its base. *Per se*, mass, and mass only, is required, and the cheaper the material and the less workmanship employed in putting them together, the greater the factor of safety that can economically be employed.

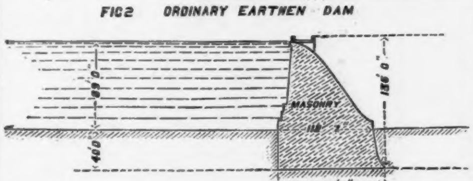
In the ordinary earthen dam there is always sufficient weight to prevent failure from either of these causes. Flat slopes are required to prevent failure from slips or deformation, and the amount of weight necessitated by these slopes is much in excess of that required for stability. In masonry dams, on the contrary, there is no outside requirement to interfere, and the section of the dam is designed simply to sustain the pressure. The exact sections required have been closely investigated, and there is not much chance of an error being made in this direction, but owing to the enormous cost of masonry dams, the tendency is to run the margin of safety very close. This applies more especially to large dams of great height.



FIC 1 DAM WITH IRON WALL



FIC2 ORDINARY EARTHEN DAM



FIC 3 MASONRY DAM (VWRNY-DEEFEST SECTION)

(2) It must either have sufficient bye-washes to carry off the maximum floods of the catchment area, or else the crest and outer face of the dam must be so constructed that the water may overflow without producing damage. This is really more a requirement of the reservoir than of the dam itself. In the case of the iron dam, the bye-washes would have to be provided.

(3) The dam must be water-tight, and must remain so under any conditions which may occur either during or after construction. Of all the requirements of a dam this is the most difficult to fulfil in practice.

Water-tightness may be secured in either of two ways—by the insertion of a continuous sheet of water-tight material, such as the puddle wall in an earthen embankment, or by constructing the whole dam of water-tight material, as in a masonry dam. Of the two the sheet of water-tight material is much the more direct and workmanlike method, but as nothing but puddle has hitherto been proposed or used, it is not looked upon with much favour. The method adopted in masonry dams of making the whole mass water-tight is a necessity of the construction from other considerations. A certain amount of tension has to be provided for in the water face of an economical section, and in any case it is better, in view of settlement, to make the whole mass homogeneous. If there were a certainty of equal settlement it would probably be found more economical to adopt a larger section and build the outer half of the dam in dry work.

To satisfy the conditions thus laid down, the water-tight material, whether a sheet or the whole structure, must be of such a nature that the workmanship and material can be thoroughly tested and inspected during construction; that no movement of the dam, from settlement either in its foundations or itself, ought to affect it; and that its efficiency should not be impaired by deterioration or corrosion.

It is on the first two of these points that the present methods of construction most signally fail. There can be no absolute certainty of the imperviousness of puddle or masonry, even with the best workmanship and greatest care, still less with cheap contract work and inferior superintendence. And, if executed with the greatest care, the slightest settlement after completion may result in failure. As regards immunity from unsound workmanship, or materials and ability to retain its imperviousness under all sorts of settlement, the iron sheet stands a long way in front of either of the existing methods. Corrosion, on the other hand, would only affect the iron dam. In practice it would not be found a fatal objection.

(4) There must be a water-tight bond between the dam proper and an impervious stratum underneath—in other words, the water-tight sheet must be carried down to it. The same remarks apply to this as to the dam itself, except that the danger from settlement is much less.

Another requirement might be added—the necessity of a water-tight stratum on which to commence operations. The want of this has probably caused as many failures in reservoir construction as anything else, but correctly it is a requirement of the reservoir, not of the dam itself. Putting this and the question of bye-washes aside for the same reason, and treating the dam and its foundation on the impervious stratum as one, we have practically two main requirements—sufficient mass, and water-tightness under all conditions. The first is very much a matter of cost, the second is a practical difficulty which has not yet been satisfactorily met.

The method now being tried in the United States evidently substitutes for the puddle wall a continuous sheet of iron, say riveted plates. The thickness of the iron might vary from ¼in. or ⅜in. in small dams where economy was an object, to, say, 1¼in. in large dams of importance, where it might be considered necessary to provide for centuries of corrosion. The plates might be either lap or butt jointed, and the joints might be either caulked or rusted up. The iron should be well tarred or painted, or coated with Dr. Angus Smith's composition. On each side of the iron a layer of asphalte from ¾in. to 1½in. thick should be carried up, and on the water side a wall of puddle 1ft. or 2ft. thick might be provided to prevent the water reaching even the asphalte. The plating would, of course, be carried right down to the impervious stratum, a trench being sunk as usual, the plating built *in situ*, and the spaces at each side filled with puddle or concrete. The wings of the dam would be carried into the sides of the valley in the same way.

The erection of the iron wall would be carried on in advance of the dam, and it would be at all times fully open to inspection. The chance of a leak hole being left would be practically nil.

Having provided the water-tight sheet, and being able to place absolute dependence on it, there is nothing else required in the dam but sufficient weight to keep it in place, and there is no reason why that should not be provided with the cheapest materials to be had on the spot, and the minimum amount of labour in putting them together. The materials must, of course, be such as would not disintegrate under water, and must be so put together that slips or settlement to any great extent would not occur under the action of water; but further than this no special care would be required. Even this limitation would apply only to the side of the dam next the water. For the outer side almost any material might be employed.

The method would be especially suitable for cases such as often occur in large water supplies in England. To secure pure water a gathering ground is selected in a clay slate, or other geologically old rock formation, where puddle suitable for an earthen dam is expensive to obtain, and the rock, if used for masonry, is of a class that produces costly work. In such a case the part of the dam next the water would be built of earth and rock, built to form a solid bank which would not settle under water, but need not be absolutely water-tight.

Theoretically, the part of the dam between the iron sheet and the water is only required to keep the iron sheet in place when the water is not there, and if the reservoir were allowed to fill as the iron sheet is carried up, the whole weight of the dam might be placed behind it, and it might be constructed of any material. This would not be possible in practice; but if good material were scarce, a compromise might be made by inclining the iron sheet, so that the greater bulk of the dam was on the side farthest from the water.

The two great advantages of the method are the absolute certainty of water-tightness to begin with, and the assurance that no amount of settlement will interfere with it. The only disadvantage is the fear of corrosion. There is no doubt that a thin plate of iron, unprotected in any way, would corrode to a dangerous extent after some years; but there is no reason why a thin plate should be employed, as the cost of the iron and its protection is small compared with th other items. If an inch plate were used, protected by asphalte on each side, the probabilities are that corrosion would not impair the efficiency of the plate for many centuries.

As regards cost, the iron dam would work out slightly higher than the ordinary earthen dam where puddle was cheap, and lower if puddle was dear. The following would be the cost per lineal yard for sections similar to the deepest part of the Vyrnwy dam, viz., depth of water, 89ft.; depth of foundation, 40ft.; total height, 136ft.:—

Fig. 1.—*Proposed Dam with Iron Wall, 1¼in. thick.*

Vyrnwy masonry was about 44s., but that is too high for comparison.

The ordinary earthen dam for this height may be almost left out of count, as few engineers would care to risk it. Comparing the iron dam with the masonry, it comes out about one-third the cost, and considering the dangers from bad construction and settlement inherent in the latter, it is undeniably the better job.

THE THAMES AND SEVERN CANAL.

The Thames and Severn Canal, which for some years has been much out of repair, and latterly impassable owing to leakages in the summit level, passes for some miles over some very bad and rocky ground, and having thus fallen into a useless condition, was last year acquired by the newly formed Thames and Severn Canal Trust to be restored, and again opened for traffic. This work is expected to he completed in about two years.

This canal is of historic and commercial interest, and forms an important link in the first line of inland navigation connecting London with Bristol, and with the counties of Gloucester, Worcester, and Staffordshire, the Forest of Dean, and the north.

It commences by a junction with the Thames at Inglesham, near Lechlade—33 miles above Oxford, and proceeds to Latton Junction, a distance of 8¾ miles, with a rise of five locks, where it is joined by the North Wilts branch of the Wilts and Berks Canal; thus forming a connection with Swindon, and thence eastwards to the Thames at Abingdon, and westwards to the Kennet and Avon navigation at Semington, and on to Bath and Bristol; it then proceeds a distance of 4¾ miles, rising by eleven locks to the summit ground at Siddington; here there is a short branch to Cirencester one mile in length.

A further distance of 3½ miles from Siddington brings us to the Thames head pumping engine, which, together with a feeder from the river Churn at Cirencester, supplies the summit level with water. The present pumping engine, 376ft. 3in. above sea level, was placed there in 1852, and pumps from a well 63ft. deep about two locks, or 120,000 gallons per hour. Two miles farther on Sapperton Tunnel, 3808 yards long, is reached; 2372 yards are lined with brick arching, and the remaining 1436 yards are in rock. This is the longest canal tunnel in England, with the exception of the Standedge tunnel on the Huddersfield Canal, which has a length of just over three miles. Sapperton Tunnel has a minimum height of 12ft. above water level, and a minimum width of 11ft. 6in. at water level. There is no towing path. A little more than a quarter of a mile from the west end of the tunnel is the end of the summit level at Daneway, and from here the canal descends by twenty-eight locks, passing Chalford and Brinscombe, to Wallbridge, where it joins the Stroudwater Navigation, making a total distance of thirty miles with forty-four locks, rising 130ft. 6in. from Inglesham to the summit, and falling 241ft. from the summit to Wallbridge. The dimensions of the locks are:—Between Inglesham and Siddington, varying 91ft. to 93ft. by 13ft.; between Siddington and Brinscombe, varying 90ft. to 91ft. by 12ft. 9in.; and between Brinscombe and Wallbridge, 68ft. by 16ft.

The first Act for the Thames and Severn Canal was obtained in 1780, and the works were at once proceeded with under Mr. R. Whitworth. The Sapperton Tunnel was esteemed one of the greatest engineering works of the day, and was visited by King George III. on July 19th, 1788, when in course of construction. The canal was opened in 1789, in which year, November 19th, the first vessel of 30 tons burden from the Severn passed into the Thames at Inglesham. Having got fairly into working order, the canal steadily improved its financial position until 1841, when it reached the height of its prosperity, and since then has declined. The last dividend was paid in 1864, and for 1871 the accounts show a loss on the year's working. In 1875 the company became carriers. In 1883 the Great Western Railway Co. acquired about four-fifths of the total shares in the undertaking, but the condition of the works on the canal showed no improvement, and the whole continued to deteriorate. On December 30th, 1893, a notice was issued announcing the closing of the canal from between Bell and Chapel locks near Chalford to Inglesham, thus leaving only 4¼ miles open.

In 1895 the Thames and Severn Canal Trust, consisting of representatives of the Stroudwater Navigation, the Sharpness New Docks and Gloucester and Birmingham Navigation Company, the Severn Commissioners, the Staffordshire and Worcestershire Canal, the Wilts and Berks Canal Company, the County Councils of Berkshire, Gloucestershire, and Wiltshire, the Town Council of Gloucester, and the Urban District Councils of Stroud and Cirencester, obtained an Act of Parliament, and took over the canal from the old company. The work of restoration is now being proceeded with, according to estimates prepared by Messrs. G. W. Keeling, M.I.C.E., and F. A. Jones, C.E., of the Sharpness Docks and Gloucester and Birmingham Navigation Company; Mr. W. J. Ainsworth, of the Wilts and Berks Canal Company; and Mr. W. J. Snape, of the Stroudwater Navigation; Mr. E. J. Cullis, A.M.I.C.E., being the resident engineer. The joint office of the Stroudwater Navigation and the Thames and Severn Canal Trust is at Wallbridge, Stroud. Mr. W. J. Snape, manager of the Stroudwater Navigation, has been appointed secretary and surveyor of the newly-formed trust, and now manages the traffic on the short open section—4¼ miles—of the Thames and Severn Canal between Wallbridge and Chalford.

The views of the canal, which we publish on pages 461 and 468, contain many features of interest, and well illustrate some of the points in its history to which we have referred. They are from photographs taken by Mr. H. R. de Salis, A.M.I.C.E., when making an inspection of the canal in January last. No. 1 shows the entrance lock of the canal from the Thames at Inglesham, and the Inglesham Round House. No. 2 shows a Pound above the three Cerney Locks, where the ruin of the canal has laid it dry. The view includes an imprisoned monkey boat, unable to proceed on account of the water having failed. No. 3 is a view of a Pound between Siddington first and second locks. No. 4 shows the east end of summit level, Siddington top lock on the right, branch to Cirencester on the left. The results of some of the work of restoration are shown in No. 5—Cirencester basin restored, wharf walls re-built, and mud

OLD THAMES AND SEVERN CANALS

For description see page 460)

removed. In No. 6, which is a view of Smerrill Aqueduct, there are some remains of a stop gate, taken from the bed of the canal. No. 7 shows Thames Head pumping engine; and No. 8 is the east end of Sapperton Tunnel. No. 9 shows the west end of Sapperton Tunnel already referred to. It was taken from the bed of the canal. No. 10, the Daneway summit lock, west end of summit level. No. 11 shows another imprisoned boat, the canal having become dry between Bathurst Meadow upper and lower locks. No. 12 is a view taken from upper sill of Tuck Mill lower lock. No. 13 is a view at Brinscombe. A view from Griffin's Lock looking towards Stroud is shown by No. 14; and No. 15 is a view at Wallbridge, where there is the junction of the Thames and Severn Canal with Stroudwater Navigation.

The Stroudwater Navigation, which connects the Thames and Severn Canal with the river Severn, is eight miles long, and descends from Wallbridge, Stroud, to the Severn at Framilode, by thirteen locks, passing Dudbridge, Stonehouse, Eastington, and Whitminster; one mile from Framilode it crosses on a level the Berkeley Ship Canal which runs from Sharpness to Gloucester. This navigation has a depth of water of 5ft. 6in., and can pass barges with cargoes of 75 tons.

The first Act of Parliament relating to the undertaking was passed in 1730, but owing to the opposition of the mill owners, which arose from the fear they entertained of losing their water, and from other causes, the provisions of the statute were not carried out. In 1759 a second Act was obtained, whereby certain persons were appointed to carry out the provisions of the former Act; these persons undertook to complete the navigation without locks, and consequently without any possibility of depriving the mill owners of water. To effect this object their intention was to shift the cargoes into boxes, and at every mill to remove them by means of cranes into other boats. Such a laborious undertaking could not succeed, though it was persevered in nearly to the ruin of the projectors. The first meeting of the Commissioners for making the Stroudwater Canal was held on 29th December, 1774; there was a delay occasioned by the company having to get two Acts of Parliament, and the canal was consequently not fully opened until 24th July, 1779, although part was in working order and opened for traffic, and the first tolls received on 3rd April, 1777.

The Upper Thames from Oxford to Inglesham, the remaining link in this through route, has not been for some years past navigable for more than rowing boats above Newbridge. It is now, however, being improved by the Thames Conservancy so as to render it navigable for vessels of 4ft. draught. The first of the new locks built under this improvement scheme at Radcot was opened in 1892, and last year the second new lock at Northmoor was completed; work is about to be commenced on a third lock at Grafton, to be followed by another near Duxford.

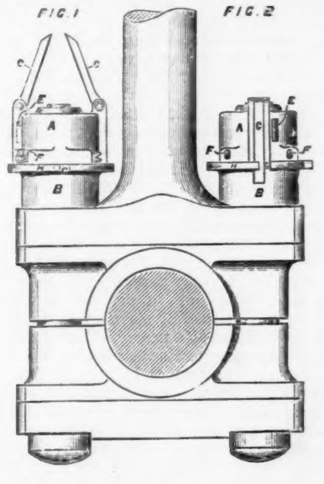
The improvements to the Upper Thames, together with the restoration of the Thames and Severn Canal, will once more restore to practical working one of the most important through routes of water communication in the country.

As a nation we at last appear to be realising to some extent that our inland waterways have been but too long neglected, and that, adapted to modern requirements, they have their sphere of utility in the carriage of heavy traffic at rates with which a railway cannot afford to compete.

DRYSDALE AND STODDART'S COMPENSATING NUTS.

We illustrate a novel arrangement brought out by Messrs. Drysdale and Co., Bon-Accord Engine Works, Glasgow, for automatically taking up the wear in crank pin or other bearings. It consists of a round nut B, having a collar H, and a separate brass cap A, inside of which is a coiled spring, one end E coming through the cap and the other end made suitable for going through a saw draught in the reduced end of the bolt inside A. Part of the nut B projects inside the cap, and has a groove all round it. Through the grooves are passed the split pins F, which thus keep the nut and cap together, while allowing them to revolve independently of one another. These nuts can be screwed on or off the bolts the same as ordinary nuts, the mode of operation in putting them on being as follows:—Hold the cap so that the end of the spring inside comes fair with the saw draught in the bolt, the pawls C being up clear, as in Fig. 1, then screw on the nut B. Meantime the cap A will not turn round, but will follow up with the nut. After the nut is up, the cap is given a turn in the opposite direction to that in which the nut was screwed, thus putting tension on the spring. The pawls C are now dropped into the notches G in the collar of the nut, as in Fig. 2, and this completes the operation. The compensating nuts will now take up, without further attention, the wear of the brasses until they are close together.

The advantages claimed for these nuts are:—(1) Saving the time spent in stripping worn brasses; (2) silent running of the parts fitted with these nuts; (3) the brasses will wear longer; (4) there is practically no initial pressure on the crank pin.



THE CRYSTAL PALACE EXHIBITION.—RANDOLPH'S STEAM COACH.

We illustrate this week on page 465 one of the most interesting exhibits at the Crystal Palace. It is a steam coach built for Mr. Randolph, one of the partners in the celebrated firm of Randolph and Elder, of Glasgow. The coach is in a very dilapidated condition, unfortunately. For this, however, the South Kensington authorities are not to blame. The truth is that the coach is not old enough to possess value as a relic. It was in a sense a white elephant, as will be seen presently. It is very difficult to obtain any information concerning its career—probably because it had none. We are enabled through the courtesy of General Festing and Mr. Last, to reproduce the following extract from the *Glasgow Herald*, of Wednesday, November 13th, 1872, which will give an excellent idea of its construction. Our drawings have been made in the Palace by our special artist.

"We had yesterday an opportunity of inspecting a new steam carriage which appears to reduce the chances of accident to the lowest point, and entirely to remove the objection of disturbance to the general traffic of the street. The carriage to which we refer has been introduced by Mr. Charles Randolph, of this city, whose eminence as an engineer is a guarantee for the soundness of the principles which it embodies. Mr. Randolph has for a considerable time given careful attention to the subject of steam as applied to street locomotion, and his plans having been matured towards the close of last year, a carriage has since been constructed, and is now ready for use—the machinery having been made by Messrs. Dübs and Co., of the Glasgow Locomotive Works, and the carriage portion by Messrs. James Henderson and Co., of North-street, Anderston.

"The carriage is 15ft. in length, and is externally a handsome specimen of the coachbuilder's handicraft. It consists of three divisions or compartments, which are harmoniously united—the driver's box in front, the boiler and engine-house in rear, with a compartment for passengers in the centre—and is carried on four wheels, two at each end. Taking these compartments in the order thus indicated, we have first the driver's box, which is roofed and closed in with side and front windows, and is set on a higher elevation than the rest of the carriage. It is comfortably cushioned, and will accommodate two passengers besides the driver. Below this box is a "boot" in which luggage may be placed, or fuel stored for long journeys. Behind the driver's box, and on a lower level, so as to be easily entered from the street, is the central compartment, which will comfortably accommodate six passengers. It is lofty enough in the roof to admit of a person of average height standing with his hat on, and is fitted with spring cushions, an umbrella or parcel rail, and hat belts in the roof, while passengers may communicate with the driver by means of a bell which is conspicuously shown. In the engine-house, which, as we have said, occupies the rear of the carriage, a seat is provided for the fireman, who takes his fuel from a coal bunk close at hand. The whole construction of the carriage is so designed as to secure order and neatness, together with the utmost possible economy of space in the working parts. When filled with passengers, and provided with water, &c., for a journey, its entire weight will be about 4½ tons.

"Passing from general details, we may now indicate the special engineering features of the carriage, in so far as these are capable of being explained to non-practical readers. Entering the driver's box, it will be seen that a lever is conveniently brought down on each side of the seat occupied by the driver from the roof. By drawing towards him the lever on the right hand, he applies brake power to both the sets of engines which drive the hind wheels, and may thus use it to stop the carriage on level ground, or regulate the restraining force of the drag, according to the steepness of the declivity down which the machine is travelling. With reference to the lever on the left hand, its purpose is to make the carriage run in either direction by acting upon the ordinary link motions, and its action is so adjusted that its relative movements are the same as those which it wished the carriage should perform—*i.e.*, pushing forward for the carriage to go forward, and pulling backward for backing. This harmony of action renders thought on the part of the driver unnecessary, and obviates chances of error; and it will be apparent to those who understand the operation, that the greater the distance the handle is made to pass through the greater will be the power of steam applied for propulsion. Rising through the centre of the compartment is a pillar surmounted by a steering wheel placed in a horizontal position. This steering apparatus is, of course, directly connected with the wheels, but by an ingenious piece of mechanism, which need not be described, it does not partake of the jolting motion imparted to the wheels by the stones and other impedimenta of the streets. The carriage, too, is protected from the unpleasantness usually experienced in travelling along rough roads, but this we shall refer to in its proper connection. We have thus noticed the principal mechanical peculiarities of the driver's box, but there are also minuter, although hardly less important, details to which we must advert. Thus, in front of the steering apparatus is placed a pointer, which unerringly indicates the position of the wheels relatively to the motion of the carriage. An important use of the pointer consists in the driver knowing before starting again the exact position of the wheels. A steam gauge is also provided, whereby the steersman may at a glance ascertain the pressure of steam in the boiler; a mercury gauge exhibiting the precise acclivity or declivity of the ground being passed over; and a mirror in front, showing the condition of the road or the traffic which may be coming on behind. The driver, again, is able to communicate with the stoker by pulling a bell, and the stoker may similarly arrest the attention of the steersman. For facility in steering, the two front wheels, which are 3ft. 4in. in diameter and 2½in. in breadth, are only 2ft. apart, while the hind wheels, which are 4ft. 6in. in diameter, and 4in. in breadth, are 5ft. 4in. apart, being the ordinary gauge of an omnibus. The latter are each provided with a spur wheel, bolted on the side next the carriage, which is driven by a pinion upon the crank shaft of each of the pair of engines. The carriage is set upon springs of improved construction. In the case of ordinary vehicles, progress through uneven streets results in more or less jolting, even where all the latest improvements have been adopted, but the springs of Mr. Randolph's carriage are so nicely adjusted, and the weight of the machine itself is so great, that the jerking motion of the wheels is not communicated in any appreciable degree to the body of the vehicle.

"It now only remains for us briefly to notice the engines and boiler. There are two pairs of vertical engines, one on each side of the carriage, with 3in. cylinders. The engines are quite apart from each other, so that, when a curve is being passed over, the engine and wheels on one side of the carriage accommodate themselves to the situation by acquiring increased velocity in proportion to the extent of the curve which is described. The carriage, we may add, can be readily turned in a street of ordinary width. As to the boiler, we notice that it is of the vertical type, and is fitted with Field's patent tubes, as also with a couple of safety valves, a water gauge, gauge cocks, and a pressure gauge. The area of the fire grate is two square feet, and the heating surface is about 80ft. The stoker is enabled to control the fire by means of a damper attached to the furnace, besides the ordinary method of working the furnace doors. The bursting strain of the boiler, assuming the material employed to be of only moderate quality, is 720 lb. on the square inch, but the metal used is of the very best description, and the boiler has been tested by the makers with 250 lb. of water pressure and 120 lb. of steam. It is not intended in practical working to exceed the 120 lb. With regard to the rate of travel, we may explain that when the pistons are running at the rate of 300ft. per minute, the carriage will go eight miles an hour. Of course this is by no means a maximum velocity; downhill, and even on level ground, it may be exceeded, but in a general way eight miles an hour is the rate aimed at. The water necessary for supplying the boiler is contained in a tank capable of holding about eight hours' supply, and is conveyed from the tank by means of two of Freidman's patent injectors. Besides serving this essential purpose, the water cistern, being interposed between the central compartment of the carriage and the boiler, tends to keep the former cool, and thus promotes the comfort of the passengers. The waste steam from the safety valves, together with the eduction from the engines, pass into a single pipe, and are carried into a chamber surrounding the funnel on the top of the boiler. This chamber is so large in proportion to the quantity of escaping steam that pulsation is entirely avoided, and the pressure is reduced to equability. The steam is discharged from the chamber into the funnel in a thin annular stream, which surrounds the effluent gases rising from the fire beneath, thus acting as a blast, and obviating the sudden screech and snort which would otherwise prove an annoyance. No steam is allowed to escape in the boiler house, and almost none is seen to be emitted from the funnel. We may add that the first trial of the carriage took place a few mornings since, when it was under the guidance of Mr. Charles R. Harvey, who has throughout attended to the details of construction. The carriage was taken from North-street, Anderston, out to Parkhead, the result of this first run being in all respects satisfactory. Mr. Randolph, we understand, anticipates that the mode in which he applies steam power to his carriage may be adapted to tramway cars, omnibuses, lorries, and even to ordinary carts."

After the coach had made a few trips, there is reason to believe that the authorities prohibited its use in the streets, and we hear nothing more of it until 1878, when it was sent to the Paris Exhibition. We believe that its owner wished to sell it, or at all events to get orders for similar carriages for use in France or Germany. Failing in this, the coach was brought back to England, and presented as a gift to the Patent Commissioners. These gentlemen did not want it, and for some years it was stored under protest by the Patent-office authorities, who had no proper accommodation for it in the Brompton boilers. They told Mr. Randolph's representatives, we understand, that it must be broken up if not removed, and the reply was, "Break it up." This was not done, and more room became available when the museum crossed the road. The revival of locomotion by power on common roads lends the coach an importance which it never before possessed. It is a very ingenious vehicle, and contains not a little that is worthy of imitation. Notwithstanding its size, it was very light, weighing, we are told, only 2½ tons empty, but its cost—£1800—was very high.

Our artist has, as far as possible, given detail drawings which explain themselves. The crank pins are set in discs, and the brake referred to in the description above consists of straps round these discs. The whole machine was very well made.

THE IRON AND STEEL INSTITUTE.

THE annual meeting of the Iron and Steel Institute was held on Thursday and to-day (Friday), May 7th and 8th, at the Institution of Civil Engineers; a fairly representative, although somewhat scanty, gathering of the members from all parts of the country being in attendance. Unfortunately the President, Sir David Dale, was unable to be present, as he has been obliged, under peremptory medical orders, to abstain from work of all kinds for a month, an abstention which must be extremely irksome to one of his well-known activity; but which, we sincerely hope, may bring him back to his accustomed strength and activity, at the end of his compulsory close time. In his absence the chair was taken by Sir Lowthian Bell, who, we are glad to see, has entirely recovered from his severe illness of last year.

From the report of the Council, it appears that the Institute continues to flourish, the number of members now on the list being 93 in excess of those of last year, while the funds show a surplus of income over expenditure of more than £1000. Considerable improvements have been made in the arrangement of the library, under the care of the secretary, Mr. Brough, and many works of special technical value have been added to the collection during the year. A powerful feature of interest in the report was afforded by the account of the arrangements for the autumn meeting of the Institute, which has been arranged to be held at Bilbao in the course of the first week of September next, an arrangement which, considering the long and tedious land journey and the want of accommodation on shore, could scarcely have been carried out without the assistance of the co-operative yachting system which has been so largely developed of late years by the Orient and other steam navigation companies. The idea has proved so popular with the members that it has been found necessary to detail one of the largest steamers in the Australian line of the Orient Company—the Ormuz—which will give facilities for visiting many interesting localities in Biscay and Guipuzcoa, besides the district immediately surrounding the meeting place. It was also announced that at the request of the Board of Trade Mr. Windsor Richards and Mr. E. P. Martin had been nominated by the Council as members of a committee which that Department has formed to investigate the question of the loss of strength in steel rails by time.

The Bessemer medal for the year has been awarded to Dr. Herman Wedding, of Berlin, an award which, judging by the applause with which the announcement was received, has been entirely approved by the members. In making the presentation, Sir Lowthian Bell dwelt upon Dr. Wedding's long connection with scientific metallurgy—a connection that may well be said to be hereditary—his family having been long and honourably associated with the development of the iron trade in Prussia; the first coke blast furnace on the Continent of Europe having been erected by his grandfather at Glenvitch, in Silesia, in 1796, which was followed by the larger works at Königshutte, built by Mr. Wedding and Mr. J. Baildon, a Scotch smelter, in 1798. Dr. Wedding is, in many respects, an old familiar friend in this country, as he was a principal representative of the German iron trade in the Exhibition of 1862, and has occupied a similar position at most of the large international exhibitions since that date down to the Chicago Exhibition of 1893, where his activity and kindness when acting as a judge in the metallurgical section will always be held in pleasant remembrance by those who were associated with him in the same work. These, however, are but small matters as compared with his literary and scientific activity, both as a teacher of metallurgy, Berlin School of Mines, and his monumental treatise on the metallurgy of iron, which originally begun as a translation of Dr. Percy's work, has in successive editions become the largest storehouse of scientific knowledge upon its subject in any language, and fully deserves the recognition made by the award of the Council. These qualifications were fully noticed by Sir Lowthian Bell in making the presentation, which was acknowledged by Dr. Wedding in a short but telling speech, in which he dwelt more particularly on his long connection with the English iron trade, including in that term both this country and America.

The first and most important communication in the list as announced, that by Mr. J. H. Darby on Dr. Mond's producer gas as applied to steel melting, was displaced from the original order, it not being quite ready for distribution, so that the proceedings began with the reading of the paper by Mr. B. J. Hall on the "Ford and Moncur Hot Blast Stove." This is the first detailed account of this apparatus that has been published, which is a somewhat remarkable omission, as it has been doing most excellent work for many years past, especially in West Coast hematite districts. The essential feature in its construction is the use of the regenerative brickwork in parallel walls 2¼in. thick, built dry and held in position by slag bricks of spindle shape section, with sharp edges in the vertical plane, spaced in zig-zig portion at small intervals. The combustion chamber is rectangular and central, traversing the full width of the stove, leaving a circular segmental space for the regenerative work on either side. These circular spaces are further divided by by a 14in. cross wall, giving four separate compartments, each one of which is provided with valves connecting it with the blast and chimney passages, so that it may be worked independently or in connection with one or more of the other three. This allows the heat of the blast to be maintained at a nearly constant temperature, one or more compartments being shut off when fully heated and held in reserve, to be brought into action as the temperature falls. In Cumberland the blast furnaces are usually worked with blast at 1350 deg. to 1400 deg. Fah., and the stoves at 1500 deg. A further valuable practice due to the arrangement of the separate valves is the power of cleaning out the bulk of the dust by suddenly changing the direction of the current from one compartment to another at the change of the stove, then the volume of air contained is driven through into the chimney, carrying the deposited material with it. This method of cleaning by discharge of the whole of the air under pressure in the stove through the limited area of one compartment has proved very effectual, and in some cases they have been at work continuously for five years without once having been laid off for cleaning.

The first stoves erected at Distington Ironworks have been in use for twelve years, without requiring any outlay for internal repairs.

The paper is accompanied by an interesting appendix, giving the statistics of the stove plant in use in British ironworks at the present time, which, though presented as incomplete, is probably only so in minor particulars. The relative proportions of the different forms of apparatus are seen in the following figures :—

Types of stoves.				
Cowper	318	and	3	building
Whitwell	120	,,	3	,,
Ford and Moncur	142	,,	13	,,
Massicks and Crooke...	64	,,	2	,,

From the details contained in the table, it appears that where Cowper stoves are used exclusively, 241 are provided for 128 furnaces, or an average of 1·88 per furnace, or in more recent cases 1·4 per furnace. With Whitwell's the figures are 91 stoves for 31 furnaces, or 2·9 per furnace, the same ratio obtaining with the Massicks and Crooke form—35 stoves for 12 furnaces. In eight cases where Ford and Moncur stoves are used exclusively, 48 serve 45 furnaces, an average of 1·08 per furnace. These figures are not in all cases quite comparable, as most of the examples of the latter class are modern and of large dimensions, but for these the proportion of three for two furnaces, or same as for Cowper stoves, is generally sufficient. The cleansing arrangement, however, gives a marked advantage to the Ford and Moncur form when the gas is dirty, and owing to the regular distribution of the gases over the chequer work it is more easily kept clean. The stove illustrated in the paper is estimated to contain 7320 square feet of heating surface in the combustion chamber and auxiliary regenerator, and 58,600 square feet in the four chequer filled compartments and passages, or 66,000 square feet in all. The height is 72ft. and the diameter 26ft., the whole being enclosed in an air-tight casing of mild steel or iron plates, a minimum space of ½in. being allowed for expansion between the casing and the brick lining. The cost of such a stove erected complete, with all mountings, but exclusive of foundations and connections, is about £1600.

In the discussion of this paper much old ground was traversed, in the matter of the history and development of the Cowper and Whitwell stoves, and some exception was taken to the author's statistics, but there was little of interest brought out. The users of the new pattern being largely confined to Cumberland and Lancashire, most of the information concerning its use came from those districts. One noticeable peculiarity not mentioned in the paper was announced by Mr. Crawford, of Moss Bay, namely, its very sparing use of gas, a point of great importance now that the power requirements for blowing are constantly increasing.

The second paper taken was that by Mr. Nursey on Mr. Dicks' "Method of Producing Metal Sections by Extrusion," which we print *in extenso* in another page. This gave rise to no discussion, other than a suggestion from Mr. Snelus that a similar method of production might be applied, at a future time, to the production of steel tubes from molten metal, following the Whitworth plan of liquid compression.

Mr. E. Metcalf Smith's paper on the "Treatment of New Zealand Magnetic Iron-sand," described the results of some experiments on the reduction of the well-known Taranaki sand. This mineral occurs as a beach deposit along a line of about thirteen miles of coast resulting from the waste of quartz and sand cliffs which are being perpetually re-arranged by the wash of the sea; a depth of 14ft. of the clean mineral having been found by digging on the shore. According to the incomplete analysis given, it contains 82 per cent. of magnetic oxide of iron, and 8 per cent. of titanic acid. For smelting it was compacted to a coherent mass by mixing it with about 30 per cent. of its weight of siliceous clay, which was then passed through a small blast furnace with a fluxing mixture of about equal parts of the same clays and limestone in the proportion of two of prepared ore to one of flux, which appears to bring the iron in the charge down to about 26 per cent. Forty-five tons of pig iron of the following composition were obtained in experimental trials in 1892 :—

	Pig iron.	Bar iron.
Iron...	94·09	98·94
Manganese	traces	traces
Titanium	1·00	0·21
Silicon	2·12	—
Sulphur	0·02	traces
Carbon	2·33	0·46
Loss and substance not determined...	0·44	0·39
	100·00	100·00

The pig iron is fairly granular, and a fragment flattens out when struck on the anvil. The bar iron is very fine grained and malleable, and is of excellent quality. The following method of treating the fluid metal will, the author thinks, commend itself. Having smelted the iron-sand, tap it into a ladle containing tarred iron-sand in the proportion of 4 cwt. to each ton of crude metal. The liquid metal will melt and absorb the iron-sand, and the tar will give sufficient carbon to retain the metallic iron in a fluid state. The metal so treated retains its greyness and fluidity, and if used for direct castings, there is a result of a gain in weight of 3 cwt. per ton, instead of a loss of 3 cwt. per ton, as is the case when re-melting pig iron for castings. In making wrought or bar iron, the tarred iron-sand compound can be added in the puddling furnace in the proportion of 50 per cent., and in making steel by the Siemens open-hearth furnace, 50 per cent. of tarred iron-sand compound may be used, yielding, together with what was placed in the ladle, a clear gain of 10 cwt. per ton. The cost of manufacture of pig iron, superior in quality to the best Scotch, is £2 7s. 3d. per ton, made up as follows :—

	£	s.	d.
Cost of fuel	1	4	0
Carriage, pugging, pressing, drying of compound iron-sand clays	0	10	3
Fluxes...	0	4	0
Labour	0	8	0
Sundries	0	1	0
	2	7	3

By the special treatment described, bar iron equal in quality to the B B H can be produced for £7 per ton. The manufactured wrought iron, when reduced with charcoal, stood the extraordinary tensile stress of fifty-two tons to the square inch.

Mr. Bernard Dawson having experienced difficulties in smelting New Zealand iron-sands in a blast furnace, asked for particulars as to dimensions of the furnace used by the author. The author, in reply, pointed out that by the use of the briquettes and the tarred sand, no difficulty was experienced in New Zealand in smelting the ore.

The last paper read on Thursday was a short note by Mr. E. A. Walford on the "Origin of Middle-Lias Iron Stone in North Oxfordshire," which he traced to the alteration of blue and green fossiliferous limestone by the infiltration of ferrous carbonate which has largely effaced the original fossils, and subsequently become changed to a rusty ferric hydrate by air and water acting through a long period. Owing to the late hour very little discussion followed, except that Mr. Snelus, while concurring with the mode of formation pointed out by the author, recognised another mode passing through the stages of calcite, ferrous, and finally ferric compounds. The meeting then adjourned till this (Friday) morning.

RAILWAY MATTERS.

Long street car rides for a 5 cent. fare are now given by the Nassau Electric Railway Co., of Brooklyn. The Brooklyn City R.R. carries passengers fifteen miles for a 5 cent. fare.

On the 13th ult. a train consisting of a locomotive and two gravel cars broke through a trestle near Bedford, Ind., on the Bedford Belt Railway. The conductor, fireman, and three others were instantly killed, and the engineer and another man injured beyond recovery. The trestle is about 75ft. high.

The North-Eastern Railway Company has announced its intention of making some reduction in their rates for the benefit of the agriculturists. The rates on town manure, farmyard and stable manure, and gas lime are to be generally reduced, and the rates for this traffic will in future be based on a very low scale. The rates under this scale are in many cases as much as 30 per cent. below the existing rates applicable over the greater portion of the railway.

The Lima (Peru) correspondent of the Panama *Star and Herald* says that the Senate has authorised the Government to make a contract for the construction of a railroad from Oroya to Chanchamayo, with a grant to the contractors of 70,000 acres of land. This road, when built, will be a most important one, opening communication between the coast and the great timber region. Propositions have been made by European capitalists for the construction of the road.

The Unopposed Bill Committee of the House of Commons passed a Bill last week sanctioning an extension of the authorised Baker-street and Waterloo Railway, in order to effect a communication with the terminal station of the Manchester, Sheffield, and Lincolnshire Railway Company's new line into London. The Bill also authorises the construction of this railway in three separate sections, each section having a distinct capital. An extension of time is also granted until March, 1901, within which to construct this railway.

The survey of the volcano Popocatepetl for the purpose of determining the best location for an aërial cable railway to the summit has just been completed. It has been determined to start the line from the ranch of Tlamacus, and it will be connected with the Interoceanic Railroad at the base, so that the business of shipping sulphur can be cheaply accomplished. This new railway will be a great attraction to tourists, who will now be able to make the ascent to the summit, 18,000ft. above the sea, and also descend to the crater, where the process of extracting sulphur is being carried out.

Japan has in operation lines aggregating 193·375 miles, of which 557·29 miles are owned by the Government. According to the latest statistics, the lines under construction make up a grand total of 719·61 miles. The *London and China Telegraph* states that a railway project of considerable importance is reported from Kyoto, by which Tsruga on the Japan Sea will be connected with Kyoto by a line along the western shore of Lake Biwa, that route being shorter than the existing Government road, which makes a detour along the eastern shore. The whole distance is 65 miles, and the estimated capital of the company, 3,200,000 yen.

The northernmost railway in the world, which extends to about latitude 64 deg., inside of the Arctic circle, is in Sweden, and serves for carrying iron ore from Gellivara south-east to the Gulf of Bothnia, at Lulea. Originally it was isolated, but in the summer of 1894, a Swedish main line, which extends nearly parallel with the west coast of the Gulf of Bothnia, was extended to a junction with it, so that now one may travel by rail from Stockholm into the Arctic zone. The main line is now to be extended around the head of the Gulf of Bothnia to the border of Finland at Haparanda, and the *Railroad Gazette* says a Finnish railroad on the east side of the gulf is also to be extended to Tornea, opposite Haparanda, when it will be possible to go by rail from Stockholm to St. Petersburg, going completely around the gulf.

The construction of the electric tramway subway through Tremont-street, Boston, Mass., has necessitated many changes in the water and gas mains previously laid in the street. On Monday, March 30th, Supt. H. C. Richardson succeeded in shifting as one piece 300ft. of 30in. cast iron water main to a line 18in. from its original position. A trench 6ft. deep and 8ft. wide was first necessary. The pipe was then cut at both ends and cross beams and jackscrews placed at 15ft. intervals, and the mains swung to these with heavy chains. When all was ready for the shift the jackscrews were turned in unison until the main had been elevated from 1ft. to 3ft., when it was shifted along timbers set on rolls to its new position and re-connected. Beginning work shortly after 10.0 a.m. Monday with sixty men, the whole operation was completed at 2.0 a.m. on Tuesday.

Comparative figures of the coal consumed per car-mile run on French tramways, employing different methods of propulsion, are contained in an article on electric lines by E. Cadiat in the *Portefeuille Economique des Machines*. As regards storage battery traction, on the lines from St. Denis to the Madeleine and from the Opera to Neuilly, the car mileage aggregated, in 1893, 502,060, or 1376 car-miles per day. The steam engines at St. Denis furnished for this service a total of 6500-horse-power hours, or 4·72-horse-power hours per car-mile. M. Badois, who reported these figures, gives 2·75 lb. of coal as the consumption per horse-power hour, and arrives at 12·98 lb. of coal per car-mile. At Marseilles, during the first two weeks of operation of the trolley system, 150,348 lb. of coal were consumed to run 19,970 car-miles, and during the second two weeks 150,975 lb. for 18,983 car-miles. The average is 7·73 lb., which, however, includes the coal used in connection with the lighting of the cars and the power station.

Mr. C. L. St. John, British Consul at New Orleans, in his report to the Foreign-office, says:—"The question of electric street cars is so important that it would not be out of place to enter on the subject. I believe no town anywhere has made more progress, and is more perfect in this respect, than New Orleans. A year or two ago the mule car system was in force, by which much time was lost, as only five miles per hour could be made; now that the transit is by electric car a speed of twelve miles an hour is obtained. In New Orleans, with an average saving to each passenger of twelve minutes, there is an economy of 10,000,000 hours a year, equivalent to 1,250,000 days' labour of eight hours. If time is money, and one day's labour is worth 4s., which it certainly is at New Orleans, the electric cars are saving the city £250,000 a year in time. In 1880 New Orleans boasted of 140 miles of tramways, 373 cars, 671 employés, and of carrying 23,716,327 passengers during the year. To-day she has 180 miles of lines carrying 47,250,000 passengers, at a uniform rate of 5 c.—2½d.—some of the distances being four to five miles. There is a project before the town council for 79 additional miles, bringing the total up to 260 miles. A quick transit not only saves time but also reduces rent, as less expensive districts can be reached by the working classes. It is only a question of time when such a system will be adopted in London and other European capitals, where at the present moment the streets are so encumbered by carriages as to convey the impression that there is no room for electric tramways; whereas it must be borne in mind that the introduction of such a system would relieve traffic by very much reducing the number of vehicles drawn by horses. At New Orleans, where in one street, the principal thoroughfare, there are no less than five lines, and the safety of the walking public is in no way protected by the police, there are few accidents. In London, where police protection is so admirably carried out, there would be far less danger than at present from innumerable vehicles driving in all directions and when least expected."

NOTES AND MEMORANDA.

In a recent paper before the Paris Academy of Sciences on "The Principal Results of the Last Ascent to a Great Height of the Balloon Aerophile—March 22nd, 1895," by MM. G. Hermite and G. Besançon, it is mentioned that at a height of eight and a-half miles the minimum temperature recorded was 63 deg. C., or a fall of 1 deg. per ·597ft.

The number of miles of streets containing water-pipes constantly charged in each water company's district within the Metropolis is as follows:—Chelsea, 96; East London, 185; Grand Junction, 135¼; Kent, 192; Lambeth, 236¾; New River, 364; Southwark and Vauxhall, 160; West Middlesex, 176¼; total, 1545¼ miles. Throughout this extent of streets hydrants for fire purposes can be fixed.

The history of the remarkable spring at the dropping well at Knaresborough, in Yorkshire, is noticed by B. A. Burrell at some length in a recent Chemical Society paper, from which it appears that its petrifying qualities were known in 1534. A complete analysis has now been made. The total solids amount to 162·435 grains per gallon, of which 114·37 grains are calcium sulphate, 25·48 calcium carbonate, and 17 magnesium sulphate. Traces of manganese and strontium were found.

In making tests of rods by the magnetometer method, it is usual to assume that as far as the self-demagnetising forces are concerned, the cylinder is equivalent to a very long ellipsoid. That this assumption, the *Electrical Review* says, is not quite true is well known, and the question has been gone into by several observers. The latest research on the question is by Mr. C. R. Mann. He finds that up to a certain value of the intensity of magnetisation, at about the point where the linear relation between I and H ceases in the reversal curve, the cylinder is very nearly represented by an ellipsoid, but after that the ellipsoid takes up a much greater magnetisation for the same magnetising force than does the cylinder. For a length ratio of 20 to 30 the deviation from the corresponding ellipsoids is a maximum.

Retort carbon is proposed as a material for the manufacture of resistances on the principle covered by a patent in Austria of Sirius Fabrik. A metre length of carbon of one square millimetre cross section would give a resistance of about 75 ohms at 0 deg. C., with a temperature coefficient of ·00052, its specific resistance being nearly 80 times greater than that of manganese copper. An adjustable resistance for arc lamps consists essentially of a quantity of the best round lamp carbons of the customary length arranged between two slate plates in such a manner as to permit of expansion, and with the necessary connections. The whole is covered with a perforated metal screen. The *Electrical Engineer* considers that there should be a place for apparatus of this class in alternating current work, since, owing to the short length required and the avoidance of the coil form, self-induction is obviated.

Concerning defective belt tighteners a writer in the Chicago paper *Milling* says:—"For a vertical belt the hinge frame is preferable and works admirably, by hinging it on trunnions at the bottom of the frame, and setting at such an angle up to the belt as will give just enough weight to hold the belt to its work. The advantage of this plan is that it gives the belt increased weight just when it is needed, and lightens up when running light. I am much in favour of tighteners on belts that have heavy power to transmit, as it is easier on both belt and bearings. By long experience I find the belt—especially rubber—retains its elasticity, and holds out much longer with the tightener properly used, than when the belt is kept strained up to its working tension all the time. Another advantage of the tightener is, that it makes possible the use of endless belts in many places, where without it they could not be conveniently used, and I think all will admit that they—endless belts—are one of the few 'comforts' of the miller. The tightener pulley should be as large as the room it has to work in will admit; not, however, to make it heavy."

At a recent meeting of the Cambridge Philosophical Society, a paper was read on "Some Scratched Stones from the Permo-Carboniferous Rocks of South-East Australia, and the bearing of the Evidence on the Question of Recurring Ice Ages," by Professor Hughes. Professor Hughes exhibited some specimens and photographs given to him by Professor David, of the University of Sydney, pointing out that the glaciation of South Australia as generally understood had been entirely disproved; that there had been no glaciers in the district in question, but that the traces of glaciation were due to ice floating from the south over a subsiding area, with, as he inferred, a compensating elevation elsewhere. He gave a *résumé* of the new evidence which he had collected in favour of the view that the recurrence of local glacial conditions was always connected with movements of elevation and depression, and appealed to physicists to explain the overthrusts and contortions of the surface of the earth, not solely by shrinkage of the nucleus nor by deformation of the whole mass, but by some conditions affecting regions limited in extent and depth, with perhaps a certain amount of periodicity determined by some more general cosmical causes

In a recent Chemical Society paper on "The Temperature of Certain Flames," by W. N. Hartley, F.R.S., the author mentions that he found no practicable means of measuring their temperature, owing to the disproportionate size of the measuring instrument—a thermo-electric couple, for instance—compared with the effective volume of the flame. He measured the temperature of flames by means of gold-leaf and with fine wires of platinum 1/3000in. diameter, such as were drawn by Wollaston and used by Faraday, also with pure platinum wire 1/1000in. thick. He furnishes evidence of the high temperature of a candle flame, not only from the melting of gold and of platinum in the flame, but by an examination of the spectrum to be seen in the mantle. Experiments made with platinum wires heated in a bats-wing gas flame are described, which proved that the carbon does not lower the melting point of the platinum, at any rate in any appreciable degree. A small carbon monoxide flame melts platinum wire 1/1000in. in thickness, and a cyanogen flame was shown to be intensely hot, for it melted such wire with extreme ease. The author believes that his experiments have dissipated the doubt that was cast on Professor Smithells' statement of the high temperature of the mantle of the Bunsen flame, and confirm his own estimate of the high temperature of the Bessemer flame.

A new method for utilising the power of a water-fall is attracting some attention in Canada, and, it is stated, a company has been formed to install an experimental plant of 175-horse power. Those who are to experiment will not get far if they have no more to go upon than the following from the *Mining and Scientific Press*:—"The essential principle involved is the compression of air by the force of the falling water, and the compressed air used to drive motors at the falls or be transmitted to a distance for the same purpose. From a tank or a standpipe, in which the water stands at the same level as above the dam, the water is permitted to pour down a pipe, around whose base are a number of holes, admitting air from tubes running up to the surface of the water. The air is sucked in and compressed by the water, and the two are automatically separated by gravitation, the air passing into a storage or supply chamber. The incredible statement is made that from 70 to 80 per cent. of the latent energy in the falling water can be rendered available in this manner. This is no more than a turbine yields, but the latter cannot transmit its energy to a distance without the interpolation of dynamos and motors, in which some loss of power occurs. It is said a plant operating on this principle is to be installed at the Dominion Cotton Mills in Magog, near Montreal."

MISCELLANEA.

The Exhibition of Horseless Carriages at the Imperial Institute will be opened to the public to-morrow.

The Japanese appreciate the value of naval power, and the necessity for ample dry dock accommodation if such power is not to be seriously hampered in time of war. Their new dry dock at the naval port of Kure is to be 464ft. long, 69ft. wide, and 42ft. deep—dimensions which would admit the docking of a 15,000-ton battleship.

Advices from Lisbon state that the Technical Commission appointed by the Portuguese Government has definitely reported to the Minister of Marine in favour of the tender of the Thames Ironworks and Shipbuilding Company, Blackwall, to build one fast cruiser, two gunboats, and one sea-going tug. Among the unsuccessful competing firms were two Italian and one American.

Concerning the stamping of patent and other forms at Inland Revenue offices in the provinces, Mr. Jackson, who has been in correspondence with Sir H. Reader Lack, the Controller of the Patent-office, has received a letter informing him that the Board of Inland Revenue have authorised their officers at Leeds to stamp in future any patent, design, and trade-mark forms which may be presented to them by the public for that purpose.

The Egyptian Government has determined to commence a geological survey. The work will be begun this year, and will take about three years for its completion, the estimated cost being £25,000. To carry out the proposed plans, Capt. H. G. Lyons, R.E., who is at present engaged under the Public Works Department of the Egyptian Government in superintending the excavation of the ruined temples of Philæ, will be employed.

Chicago has a complete telephone and signal system, consisting of 887 public and 370 private boxes, operating on 81 circuits, connected with the 37 precinct stations of this department, in which they are located. The system includes public sentry boxes placed at street intersections, equipped with a signal box to transmit the number of the station; a telephone for patrolmen to report and receive orders over; a chemical register at the station which records the calls, and the necessary switches for operating the telephone and testing for electrical disturbances.

At the last meeting of the Council of the Royal Agricultural Society, Mr. Frankish, from the Implement Committee, reported that the total number of implement stands at the Leicester meeting would be 445, and that, exclusive of open ground space, a total of 13,930ft. had been allotted in the Implement Department. At the trials of potato planters, held at Leicester on April 21st last, the judges had awarded the prizes as follows:—First prize of £20 to Messrs. Ransomes, Sims, and Jefferies, of Ipswich, for their double-row potato planter; and the second prize of £10 to the same firm for their three-row potato planter.

According to the United States press reports, the Japanese Government has made arrangements with the firm of Sir W. G. Armstrong and Co., Newcastle, England, for the erection of a steel foundry in Japan. The terms are as follows:—(1) The material shall for the present be imported from England; (2) of the workmen to be employed, 20 per cent. shall be brought from England and 80 per cent. shall be Japanese; (3) when a new arm is invented in England, it shall be manufactured at the works in Japan; (4) for a stated number of years the Japanese Government shall give a fixed subsidy to the company; (5) on the expiration of the period during which the company receives a subsidy the works shall be sold to the Japanese Government.

At the eighth annual general meeting of the Tarapaca Waterworks Company held on Monday at Winchester House, Mr. R. Harvey, who presided, said the net profit for the period under review, amounting to £52,020, was upwards of £3000 in excess of that of the preceding year, and was equal to 13 per cent. on their capital. The Board had, however, decided to pay a dividend of only 7½ per cent. By doing this they were enabled to carry forward the substantial sum of £20,000, after placing £10,000 to the reserve fund for the redemption of debentures. When the company was formed Iquique had only 20,000 inhabitants, whereas the population to-day was 33,000, so that the question of providing for a growing demand was one that could not be neglected.

It is stated that the parties to the proposed transfer in the Durham coal trade are the Earl of Durham and Messrs. James Joicey and Co. The output of Lord Durham's collieries, which are fourteen in number, is 12,000 tons per day. The purchase money is put down at from £800,000 to £1,000,000 sterling, and it is understood that the transfer will become an actual fact on June 1st. Messrs. Joicey have at present under their control about thirteen collieries, employing 4000 men, and the number employed in Lord Durham's pits is over 8000, so that when the transfer is effected Messrs. Joicey, of which firm the leading partner is Sir James Joicey, M.P., will have control over nearly thirty collieries and 12,000 men. The Lambton steamers, which carry most of the coal won from Lord Durham's pits at Sunderland, are twenty in number.

Some interesting facts concerning the competition of the Continent and America in the iron trade were given at a conference, held under the auspices of the British Iron Trade Association, at the Westminster Palace Hotel, London, on Wednesday, Sir Alfred Hickman, M.P., in the chair. Previous to the conference the annual meeting of the British Iron Trade Association was held, at which the report of the board, presented by Mr. J. Stephen Jeans, the secretary, set forth that the trade of 1895 had not recovered the ground lost since 1892, but that it was interesting and encouraging to note that, if the export trade of the rest of the year had been as good as that of December last, the value of exports would have been nearly 2,000,000 tons more than reported. The principal features of the export trade of 1895 were:—(1) The large increase in the shipment of plates and sheets, which reached the unprecedented total of 707,000 tons; (2) a slight improvement in the export of tin-plates; and (3) an increase of 44,000 tons in the export of rails. Our imports of iron and steel had shown an increase in 1895 over the preceding year under all heads except tires and axles.

For many years shipowners have declined to carry petroleum as cargo unless it has been guaranteed by the shippers as complying with the conditions imposed by the Petroleum Acts—namely, that it would not give off an inflammable vapour at a temperature of less than 73 deg. Fah. The inquiry proceeding by a Select Committee of the House of Commons has, however, suggested the necessity of some declaration making it clear that, when petroleum is about to be shipped as part of a general cargo, responsibility for compliance with this condition of the Act of Parliament rests solely with the shipper. The committee of the London Direct Short Sea Traders' Association, under the presidency of Mr. R. Cattarns, have therefore formulated the following petroleum clause, which will henceforth form part of their authorised bill of lading for oversea purposes, and also be inserted in the way bills used in the coasting trade:—"The shipowners refuse to carry petroleum which gives off an inflammable vapour at a temperature of less than 73 deg. of Fahrenheit's thermometer. Shippers will be held to guarantee the petroleum they ship will not give off an inflammable vapour under any circumstances at a temperature of less than 73 deg. of Fahrenheit's thermometer, and the consignees of the goods will be held responsible for all the consequences and legal penalties attaching under the Petroleum Act of Great Britain or elsewhere in the event of their shipping petroleum of a nature such as that above specified. Clause 12 of the authorised form of Continental Bill of Lading shall apply to this shipment."

THE PRODUCTION OF METALLIC BARS OF ANY SECTION BY EXTRUSION AT HIGH TEMPERATURES.*

By Perry F. Nursey.

So comprehensive are the developments of inventive genius in the present day, and so rapid and far-seeing are the strides made by invention, that they not unfrequently overtake, or rather overreach, the means at disposal for giving practicable form to otherwise practical ideas. Thus it sometimes happens that the introduction of an invention based upon common sense lines is temporarily retarded, or the invention itself permanently lost to the world, and industrial progress in a given direction thereby checked, by reason of there being no adequate means or suitable materials at hand for bringing it to a successful issue.

A case in point is afforded by the carrying out in practice of the ingenious metallurgical process which I now have the privilege of bringing before the Institute. The invention, which is that of Mr. Alexander Dick, deals with the production of all kinds of metallic sections, from a simple round wire to complex designs which it would be impossible to roll, by forcing metal heated to plasticity through a die under hydraulic pressure. The principle is simple enough, being nothing more than that employed in the manufacture of bricks, drain pipes, and similar articles. It is, however, the application of that principle to the purpose under notice that constitutes the ingenuity and originality of the invention, and which marks it as a substantial advance in metallurgical practice.

I do not forget that the principle of extrusion has been applied in the production of continuous lengths of leaden pipes and wire, and also of leaden rod for the manufacture of projectiles for small-arms, and for other purposes. In those cases, however, the lead is pressed at a comparatively low temperature, whilst in the present instance the metal is operated upon at a very high temperature, namely, that of plasticity, or about 1000 deg. Fah., and which varies considerably with different metals and alloys. It was this necessary condition of high temperature that led to the difficulties encountered by Mr. Dick in putting his invention in practical shape, and which difficulties present features of interest to steel makers.

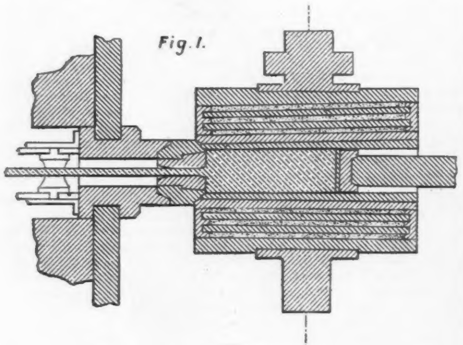


Fig. 1.

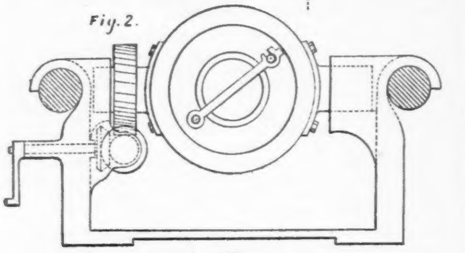

Fig. 2.

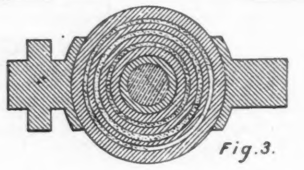

Fig. 3.

The process of manufacture consists in placing the heated metal in a cylindrical chamber, at one end of which is a die. Upon pressure being applied at the opposite end, the plastic metal is forced through the die, issuing therefrom as rods or bars of the required section and of a length governed by the quantity of metal placed in the receiver. This pressure chamber has not only to withstand the high temperature of the contained metal, but has likewise, whilst under the influence of that temperature, to meet the severe strain brought upon the interior by the resistance of the metal to the pressure of the hydraulic ram in forcing it out through the contracted area of the die. Hence the first and most important point to be settled was the design of the cylinder and the material of which it should be constructed. Other difficult problems presented themselves for solution as the work of construction progressed, but they were of a less anxious and perplexing character than that of the pressure cylinder, which is the main feature of the invention.

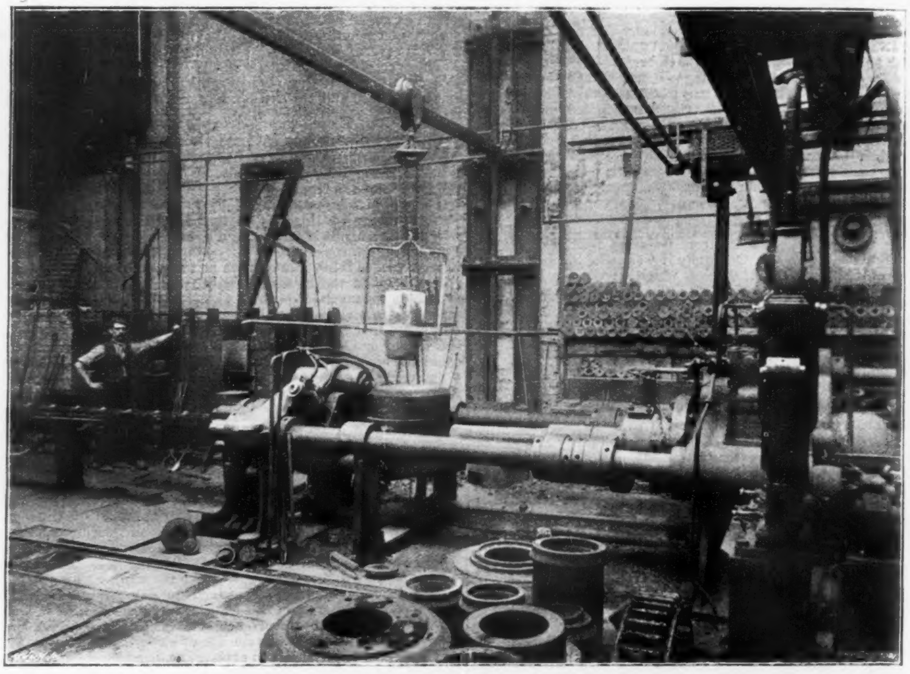
At starting several cylinders were made, some of cast and some of wrought steel, in order to ascertain which material was best suited for the purpose. The chamber was 24in. long and 6in. diameter internally, the walls varying in thickness from 3in. to 6in. Surrounding the cylinder was an annular chamber heated by a coke fire, the object of which was to maintain the plasticity of the metal during the operation of pressing. In practice, however, it was found that the strains set up by the unequal expansion and contraction of the walls of the cylinder, added to the internal working pressure, soon developed cracks, thereby rendering the cylinder useless.

A series of experiments was therefore carried out by Mr. Dick, with the object of finding a steel capable of standing the temperature and pressure to which the container was subject in working. To this end he obtained cylinders of various steels from several leading steel makers, which he tested under working conditions both of temperature and pressure. In the result, however, he found that not one of the cylinders would stand more than three tons per square inch at the working temperature, Delta metal being the material operated with. In all cases the cylinders bulged and developed longitudinal cracks, through which the metal was forced. Thus for a time the progress of a promising invention was retarded, and the accomplishment of an important object rendered extremely doubtful.

Nothing daunted by failure, Mr. Dick set to work to devise other means whereby he hoped to accomplish his end. In due course, and after the expenditure of a considerable amount of both time and money, he succeeded in producing the machine which I am about to describe, and which admirably fulfils its intended purpose. The difficulty respecting the pressure chamber, or container, was eventually overcome by dividing up the container into sections composed of concentric steel tubes alternating with annular spaces packed with a dense non-conducting material. This arrangement is based upon the principle that whilst steel, when heated to a high temperature, loses its integral strength, as proved by Mr. Dick's experiments, yet at lower temperatures it will retain its full power to resist pressure; so that a cylindrical chamber formed of several comparatively thin walls, and protected from extreme heat, will resist pressure better than a chamber having a thick solid wall heated to a higher temperature. A chamber surrounded by comparatively thin walls heated to a comparatively high temperature is not so injuriously affected by variations of temperature as a similarly heated chamber having a solid wall of greater substance.

By this compound system of construction, the liner, which is exposed to the extreme heat of the metal, may be made with a comparatively thin wall, and will not be liable to be fractured by unequal heating and cooling, and consequent expansion and contraction. Further, in order that it may be capable of successfully resisting pressure, it is reinforced by means of the surrounding steel tubes, which, although of themselves thin, are insulated and supported by a dense packing of non-conducting material, and are therefore kept at a comparatively low temperature and in a condition to offer the greatest resistance, which condition is further mechanically influenced by a stout steel outer casing.

Another problem which took some time to solve was the selection of an efficient non-conducting material. The main conditions here were, that the particles of the material employed should be capable of being densely consolidated, should not injuriously affect either the liner or the outer cylinders, nor melt nor become decomposed at a high temperature. After experimenting with a variety of substances, Mr. Dick found that the best results were obtained from crushed granite mixed with a small proportion of borax. This compound satisfactorily fulfilled all the necessary conditions, and was therefore adopted as a non-conductor.



DICK'S APPARATUS FOR MAKING BAR

The apparatus as now constructed and in daily operation is illustrated in perspective below. It is 16ft. in length, 6ft. wide, and 5ft. high over all. It consists mainly of the compressing cylinder or container and the hydraulic ram. A longitudinal section of the container is shown at Fig. 1, and a transverse section at Fig. 2. The container, which is 2ft. long and 2ft. diameter externally, has an inner liner of cast steel. The internal diameter of the liner varies in different containers from 5in. to 8in., according as to whether it is wanted for pressing a small or a large charge, the container being changed as required. The liner is enclosed within a series of cylinders of ordinary mild steel spaced about ⅜in apart, the annular spaces being filled in with non-conducting material. The container is mounted on trunnions and fitted with worm-gearing for bringing it to a vertical position for being charged with metal and restoring it to the horizontal for the operation of pressing.

Great care has to be exercised in making the die plates, the material of which is tungsten steel. They are formed with either one or several openings, each opening being of the section required to be given to the article to be produced. The edges of the openings in the dies are bevelled, so as to give free access to the metal under pressure, and to more perfectly condense it. The die plate is mounted in a holder, in which it is easily fixed, or from which it is readily removed, as different sections are required to be pressed. As it is necessary to heat the die and its holder previously to each pressing operation, the die is fitted into a shouldered recess in the holder, which is coned to seat into a hollow metal block. This block is firmly held in position during the operation of pressing by a pair of gripping jaws actuated by hydraulic power. The die-holder and the gripping jaws are carried in a strong crosshead. The die-holder and its adjuncts, together with a number of dies, as well as a container, and some of the steel cylinders used in its construction, are seen in the perspective view of the machine.

The metal is forced out of the container and through the die by a hydraulic ram 18in. in diameter, and working under a pressure of two tons per square inch. The ram has a prolongation or extension, of reduced diameter, which forms the plunger of the container, entering it at the opposite end to the die. A different plunger is used with each container, the diameter varying to suit the internal diameter of the container. On starting to work each day, the container is first heated up by gas with a Bunsen burner, which quickly brings the liner to the temperature necessary to prevent the first charge of metal getting a chill. The container does not require re-heating, as the liner remains red-hot after each run.

The working of this ingenious system of production will be best described from my own observations during a recent visit to the Delta Metal Works, Pomeroy-street, New Cross, London, where it has been in regular commercial operation for some time. Upon that occasion the machine was running on an order for Delta metal rods 12ft. long by 1in. diameter. Of course much greater lengths and much heavier sections are turned out as required. The great variety of sections produced, some of very intricate character, is shown by the specimens on the table. The specimens are samples of work ranging from light sections, such as wire weighing about $\frac{1}{100}$ lb. per foot run, to heavy rounds, hexagons, and squares weighing 40 lb. and over per foot run. The die in use on the occasion of my inspection had four openings, thus producing four lengths, or an aggregate of 48ft. of rod at the same time.

A charge having just been put through, the opening at the front end of the container—that next the die—was closed by a removable plate or stopper, as shown at Fig. 3, and the container was turned into a vertical position. A charge of 1½ cwt. of molten metal was then poured from a ladle into the container, and was allowed to stand for about six minutes, so as to acquire a plastic condition. The diameter of the plunger and that of a loose block which is placed between it and the charge—for a purpose which I will shortly explain—being less than the diameter of the steel liner, the plastic metal when under pressure would be forced backwards between the block and the liner were it not restrained. In order to prevent this back-flow taking place, a dished steel check disc, which is less plastic and more rigid than the heated metal at the working temperature, is first placed on the top of the charge, and when the pressure is brought on the disc is expanded, and completely fills the bore of the liner, thus effectually preventing the back-flow of the metal.

Upon this check disc was then placed the loose steel block just referred to, which, having been previously heated, prevents the cold end of the plunger chilling the charge of metal. The plunger being of smaller diameter than the liner, there is no fear of the latter becoming chilled by the former. To preclude the possibility of such an occurrence, the back of the loose block is recessed to receive a corresponding projection on the front end of the plunger, which is thus kept horizontal in its forward travel, and prevented from coming in contact with the liner.

The loose block having been inserted, the container was brought into a horizontal position, the stop plate removed, and the container run up to the die block, which, with the die, had been previously heated. The hydraulic pumps were then started, and in four minutes the charge was expelled and had become converted into four 1in. rods, each measuring over 12ft. in length. The clips were then released, and the ram continued its forward travel, pushing out the remaining metal or stump, together with the die and its holder, as well as the check disc and the loose block, leaving the container perfectly clear for a fresh charge. The rods were at once cut off from the stump or fag end of the charge to the exact length required and removed. The die and holder were then replaced by others, the container turned over into a vertical position, the stopper fixed in place, a fresh charge of metal teemed in, and as soon as it had become plastic the operation of pressing was again proceeded with. I may mention that the rate of travel of the ram can be varied to suit the size of the charge or the special nature of the output.

With regard to the physical characteristics of the bars thus produced, it is obvious that, owing to the great pressure put upon the metal, its quality must necessarily be greatly improved, in the same way that Whitworth steel is improved by compression. In the first place, it is found to be perfectly homogeneous. The actual increase of strength in extruded bars over that of hot rolled bars of the same metal varies with the nature and composition of the metal or alloy. Taking ordinary yellow metal, the increase in tensile strength is 24 per cent., with a proportionate increase in elongation. Some tests made at Woolwich Arsenal with Delta metal bars produced by extrusion show a tensile strength of 48 tons per square inch, with 32·5 per cent. elongation on 2in., against 38 tons per square inch tensile strength, and 20 per cent. elongation of rolled bars of the same metal. The samples exhibited have not been touched since they left the dies, and it will be seen that the surfaces are perfectly smooth, and that the various specimens require no further finish.

I have stated that at the time of my visit the mode of procedure was to charge the container with molten metal. The objection to this method of working is the delay occasioned at the press in waiting for the molten charge to set or become plastic, besides which there is the time occupied in various detail operations attending the charging of the container with molten metal. The result is that the average rate of working is only twenty-five charges per day of ten hours. This method of working has since been improved upon by Mr. Dick, and the container is now charged with billets after they have been heated to the point of plasticity in the furnace seen on the left in the view. With this method of working the output is doubled, easily reaching fifty charges and more per day, the labour cost per ton on the finished work is very small, being only the wages of two men and a boy per machine.

A larger press is also in course of construction which will have a 20in. ram, and will be capable of turning out heavier work than any yet produced. Besides being in operation at the works already mentioned, the system is being worked under licence in the Midlands, and it has also been adopted in the Delta Metal Works at Düsseldorf.

It will thus be seen that we have, if not a new industry, at any rate a new industrial process, and one, moreover, which is of far-reaching importance. Having accomplished so much, it is not outside the bounds of possibility that, given an improved

---

description of steel or other metal for the dies, other metals, such as iron and steel, which are less ductile and less expensive than those to which the system is at present applicable, may be used for the production of a still wider range of articles by extrusion. As a matter of fact, Mr. Dick is at the present time engaged upon experiments with the view of producing sections in iron and steel similar to those exhibited. Should he prove successful, I shall hope to have the pleasure of placing the results before the Institute.

LETTERS TO THE EDITOR.

(We do not hold ourselves responsible for the opinions of our correspondents.)

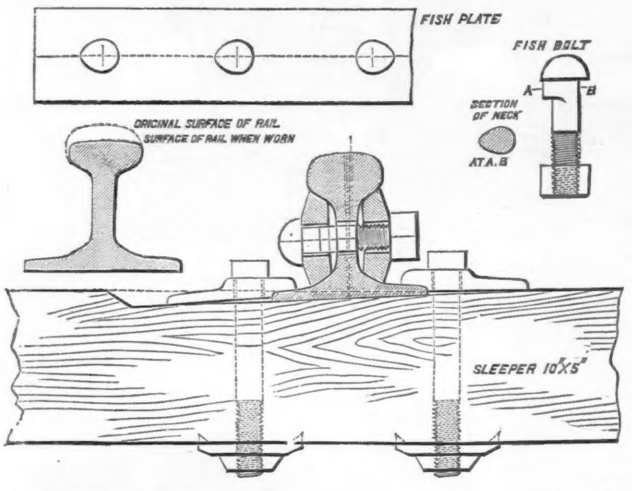
PERMANENT WAY.

SIR,—To the many communications which have been appearing of late in THE ENGINEER perhaps the addition of the following may not be found uninteresting. In the year 1870 the construction of a short branch, called the Taff Bargoed Railway, was committed to the late Mr. Edward Wilson and myself by the Great Western and the Rhymney Railway Companies, as joint owners of the line. At that time iron was very dear, and it was thought desirable by the committee to economise as much as possible in the use of that material. At that time the double-headed rail with cast iron chair was the prevailing form, although the bull-head was already coming into favour. To carry out the wishes of the committee, we decided to recommend the use of the Vignoles rail, whereof I enclose a full sized section, showing also the method adopted of placing it upon the sleeper. The rails were of Bessemer steel, but at that time the steel produced by the manufacturers was not considered so trustworthy as it is now found to be; in fact, it was thought liable to break off short in very unaccountable ways, particularly at places where the grain might have been interfered with by bolt holes or otherwise. It was, therefore, determined to have no holes or notches in the bottom flange of the rail, but to fix it on the sleeper by means of clips as shown on the drawing. The bolts, ⅞in. in diameter, were made to pass through the sleepers close to the edge of the rail, so that the clip has the greatest possible leverage on the rail to prevent canting.

The bolt heads were made square to enable them to be screwed by a key from the upper side of the sleeper, and the nut on the under side was made 3½in. square and perfectly flat so as to have a good bearing upon the sleeper, with the corners turned up sharp so as to go into the wood and prevent turning.

The sleepers were of Baltic redwood, creosoted, measuring 10in. by 5in.

The foot of the rail was 5in. wide, so that the bearing surface upon each sleeper was 10in. by 5in. = 50 square inches. The seat of the rail was slightly bevelled by adzing the sleeper so that the inside edge of the rail lay about ⅜in. below the level of the top surface of the sleeper, while the other edge lay upon the surface. By this means a slight cant inwards was given to the rail. This cant was on both rails alike and independent of the super-elevation usually given to the outside rail on a curve. The joints were protected by fish-plates of the most ordinary form and size, fastened by bolts 1in. in diameter of the form shown on the drawing. It will be seen that when first laid the under side of the clip is about ½in. clear of the upper surface of the wood of the sleeper. In the course of using the rail sinks into the sleeper, and the clip is made to follow it by screwing down the fang bolt that holds it, and when the sinking has gone so far as to bring the clip down to the wood it is removed and the seat adzed down so as to restore the original clearance.



Upon the branch railway where this arrangement is used the traffic, mostly coal and ore, is worked by tank locomotive engines weighing with coal and water 56 tons, and about forty trains per day run over each line of rails at a speed of from ten to forty miles per hour, though possibly a forty-mile speed may not often be attained. In practice it has been found necessary to re-seat the clip after eight or ten years' use of the way, after which it has hardly been found necessary to re-seat again during the life of the sleeper. The average life of the sleepers in the main way may be taken to be about fifteen years, though some are still in work after twenty-one years.

On straight roads, one fang bolt in each sleeper on each side of the rail is used; but in order to prevent spreading, a second bolt is introduced on the outside flange of the outside rail in all curves under 15 chains radius, although, in truth, very little tendency to spread has been noticed, possibly on account of the rail very soon embedding itself in the sleeper. And it is not found, in taking up an old road, that the fang bolts have in any way widened the hole in the sleeper; but a slight indent is sometimes found on the flange of the rail, and a corresponding indentation on the side of the bolt, say $\frac{1}{16}$in. deep. The weight of the rail is 80 lb. per yard, of the fish-plates 22 lb. per pair, of the fish bolts about 1¼ lb. each, and of the fang bolts with clips 4⅜ lb. each. On account of the strength of the bottom flange of the rail, or, rather, because of the inequality between the bottom flange and the head, it is found difficult to bend these rails cold, and care has always been taken to get a due proportion of rails bent to various curvatures while hot from the rolls, at the same time one-half of each lot of bent rails is cut a little shorter—say, an inch more or less, according to circumstances—to account for the difference between the lengths of the inside and the outside rails on curves. The average length of the rails is 30ft., and eleven sleepers are used in that length; the sleepers on each side of each joint being placed 2ft. apart centre to centre, and the intermediate sleepers 2ft. 9½in.

The road thus made has been found quite strong enough for the work it has to bear, though it is possible that if greater speeds and heavier locomotives were required for the traffic it might be thought necessary to add to the weight of the rail, and perhaps to the size or number of the sleepers.

Upon the road here described the trains are found to run very smoothly, and possibly all the better for the absence of hard cast iron chairs. Given the same weight of rail, of course the way is cheaper than a chair road by the cost of chairs with keys and cushions, which saving may amount to 3s. 6d. per yard. Also the way is found to be cheaper to maintain by about £25 per mile of single way per annum. I give a section of the rail when worn, showing by a dotted line the original form of the top. It is found that when the rail is thus worn, and removed from the main way—though fit to last for many years in station and standage sidings—the rail has lost about 12 lb. per yard of its original weight; yet when worn to that extent, though still in work, I have no recollection of any cases of breakage or other symptoms of weakness, unless that a little more packing may be required under the sleepers. Viewed as a girder the great strength of the bottom flange will probably account for this. Upon the whole, this form of permanent way proved so satisfactory on the branch where it was first used that it has been adopted as the standard system on the whole Rhymney Railway, upon which none of the original double-head rails now remain.

In laying the way the road bed was carefully made, the formation well drained, and the carefully selected ballast was clean and hard, contributing no doubt to the success of the way; but in truth no form of road can give satisfaction unless due attention be given to these points.

I have always here used wooden sleepers, and for them I have a preference on account of the easy running of the trains on them. Also, as long as good creosoted sleepers can be bought for 3s. 6d. to 4s. each, I think they will in the long run be found to be cheaper than those of steel at, say, 7s. 6d. each, while the outlay of capital in the first laying is to the extent of the difference reduced, which is often an important point in the early history of a railway. Thus, supposing the average life of the wooden sleeper to be fifteen years and of steel thirty, which is very doubtful, the difference in first cost added to compound interest on the same for fifteen years will give an amount sufficient to restore the road at the end of fifteen years. Beyond this, however, I have nothing to say against the use of steel sleepers, which no doubt are invaluable where timber may be scarce, or in many situations, as in India, where wood—except teak, perhaps—is quickly destroyed by the white ant and sundry grubs.

Cardiff, May 1st. CORN. LUNDIE, Engineer.

SIR,—Mr. J. Whitestone, in his letter in THE ENGINEER of the 17th, still harps on his pet theory of the rigid and uniform road, but he does not explain the reason why this kind of road proved such a terrible failure on the Manchester and Leeds Railway. He only refers to it as the "lathe bed."

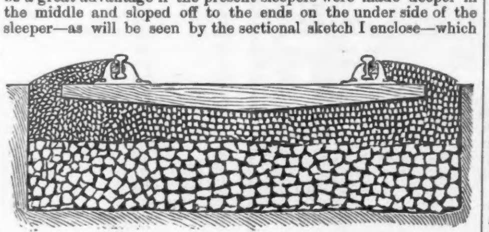
Mr. Jessie Hartley made parallel walls of granite quite uniform, straight, even, and rigid. The rails were bolted direct to the granite. It was a daily occurrence to have springs and tires broken owing to the excellent rigidity of the road.

The main point with Mr. J. Whitestone seems to be, firstly, to have a perfectly uniform line; secondly, to have it rigid. Now, I fail to see how a road could be more uniform than when the rock was dressed to a surface and more rigid than when the rails were spiked direct to the rock. This road, and also Mr. Hartley's parallel walls, seem to fulfil all that Mr. J. Whitestone requires, yet both these roads have proved—as all rigid roads must prove—a miserable failure.

He talks a good deal about the sleepers not being rigid enough, and then goes on to assume that the ballast has not sufficient stability, and recommends that stone ballast should be used instead; and says, in his opinion, steel sleepers should be used. I have used these steel sleepers myself in the Argentine Republic, and have seen the practical results with them. Mr. J. Whitestone seems to have had exceptionally good luck in his steel sleeper trials. I wish I could say the same. Steel sleepers will answer all very well where earth only is used, but where stone or any hard ballast is used they will not answer, as the difficulty of packing up these steel sleepers is very great, owing to their being hollow, and if they are not uniformly packed they are apt to buckle and break off the jaw which holds the key, and if only one jaw is broken the whole sleeper is useless until it is taken to the permanent way shop to have a new jaw put on. Not so with the wooden sleeper, which can have a new chair put on on the spot. I have tried these sleepers with broken brick, as stone is so expensive and brick is so cheap in the Argentine, and have found that the great amount of vibration caused by them works out the keys; this is not the case where earth only is used.

With regard to the springing of the sleepers, this is very slight as compared to the depression of the sleepers in the ballast. I should recommend that the sleepers should not be increased in thickness, but increased in width, so as to give more bearing surface to withstand the sudden pressure brought to bear on the sleepers under the rails.

Whilst on the subject of sleepers, I would propose that it would be a great advantage if the present sleepers were made deeper in the middle and sloped off to the ends on the under side of the sleeper—as will be seen by the sectional sketch I enclose—which would give it less bending tendency and would retard a good deal of lateral movement, and would act like an invert would to a culvert.



The hard wood sleepers that they use in the Argentine Republic, without any creosote or tar, and which is as hard as boxwood, and some harder, is used for the points and crossings, and by some railways entirely. With sleepers made with this kind of wood there is very little deflection, and a plain spike holds very firmly in this wood and does not get loose by time. I have seen a good deal of trouble experienced in taking out spikes to replace a broken chair. With sleepers made of this hard wood, as I suggest, and 12in. of good stone bottom ballast, and 7in. of stone top ballast, brought up over the ends of the sleepers to cover the keys, which keeps them from working out and protects the ends of the sleepers from the sun, and prevents a good deal of lateral play, with a 50 lb. chair for four spikes and a 90 lb. bull-headed steel 30ft. rail, properly packed and boxed, I feel sure we should have a road where there would be little need of complaint.

Stone ballast is the best; it has given the best results, and is largely used by the Great Western Railway. But there are some kinds of stone utterly unfit for railway ballast—for instance, a stone of a soft crumbling nature, which powders much, is very bad, as, in the first place, it binds too much and forms into too compact a mass, and then it is very bad for drainage, and in wet weather becomes very soft and absorbs a large quantity of water. Broken trap rock, however durable in itself, would pack to such an extent as to form into the condition of a solid ledge, which the rails would soon batter out. Limestone rock is quite durable, but it is of so binding a character as to pack too readily when used as ballast. Another class of stone which is unsuitable for ballast is slate rock; it is the poorest kind of stone, being rapidly decomposed in wet weather. A very suitable rock for ballast is gneiss rock; it is not hard, and breaks easily, thereby making it cheaper than hard rock, as rock for top ballast should never be larger than two cubic inches. On the Eastern Counties Railway they use broken sandstone, which, although soft, is preferred as affording an easy road.

A casual observer, passing by sleepers packed with a ballast which does not drain properly after rain, would not see much amiss with the road, but should a train pass by whilst he is there, he will see that each sleeper will go up and down with a hammering noise as the wheels pass over them, squirting out liquid muddy water, which after a time washes away the ballast from under the sleeper; the rail brings the chair and sleeper up to the level again after the wheels have passed. When the road gets into this state, if not discovered, it often remains like this for some time, and obliges one to open up the road until it is dry. Nothing is more fatal to a good road than a ballast which will not drain the road properly. A good ballast to a road is like a good foundation to a house, and no matter however good our superstructure is, we shall never obtain a good foundation with ballast which does not drain properly, and which has not sufficient elasticity. To my mind there is not sufficient attention paid to this serious question by the head engineers of railways, and the ship is often spoiled for a halfpenny worth of tar.

I think there can be little doubt that single driving wheel express engines try the road much more than four-wheel coupled engines, as the weight in the latter is more equally distributed than in the former, which have on some lines as much as 18 tons on the driving wheels only; and as there is more demand for increased speed—and these engines seem to be favourites for this—there is likelihood of this trouble increasing, as more speed means more power, and in the single wheel it is no good to increase the power without increasing the adhesion, which means more weight on the drivers.

Mr. Rose in his letter suggests what he calls an altered form of permanent way, but which is a mixture of the old longitudinal road of the G.W.R., which they have condemned and are doing away with, and the present sleeper road. Mr. Rose says that the rail is to be a Vignoles rail, and is to be fastened to the longitudinal by coach screws, which are not so firm as the old bridge rail of the G.W.R., which was held down to the timber by a fang bolt, which did not hold it at the edge as the coach screw would, but passed through a hole in the rail. He then says that there are to be ten sleepers in a 30ft. length, which will bring the sleepers 3ft. centre to centre, and give a clearance of 2ft. 2in. between the sleepers—that is to say, with 10in. sleepers. Additional sleepers are then to be driven in, which, with a sleeper of 10in. wide, will reduce the clearance of 2ft. 2in. to 8in., which would make it impossible for a navvy to beat up the road properly, as there would not be room enough horizontally for his beater to work. The lateral pressure brought to bear on the rail, especially on curves, breaks the jaws off the chairs, which breakage is very much on the increase on lines which key on the inside. The system of inside keying is too rigid for the class of cast iron chair we frequently have to use now, which is often made of mixed scrap, and is a very poor sample of cast iron. Where the road is keyed on the outside, a yielding substance receives the blow. This is why Mr. Barlow's wrought iron key did not answer, being too rigid. I wish we had cast steel chairs; then the large amount of broken chairs would be considerably reduced, and we should have made then one good step in the right direction.

The material of a permanent way does not go through the severe tests that material does for locomotives. And why should it not? How are we to tell what kind of material we are using unless? I have seen a 5in. bull-headed steel rail break clean through, not more in any place than $\frac{3}{16}$in. out of square. Then, again, look at the amount of fish bolts that break off in screwing up, all due to inferior material. Grover's washers for fish joints is a capital invention. If they were used more universally, we should run less risk from nuts working loose. I saw an experiment tried on a West of England line with Grover's washers, with bolts which had loose nuts on them. They were put to a joint on the main line, and heavy and fast express trains passed over the joint, and the nuts never worked loose. The joint was carefully watched during the trial.

Mr. Samuel and Mr. Adams invented a special chair for the rail joint, and I had fish-plates with a flange at right angles to the web of the rail, with holes in it intended to spike down on top of an extra large sleeper; but they have all proved a failure on account of the want of elasticity. The best kind of joint is the suspended joint, with Grover's washers and fish-plates, which nearly meet under the rail, and, where the sleeper is put as close as possible, each side of the joint, without interfering with the driving home of the keys. The Barlow saddle-back wrought iron rail, and the iron longitudinal system tried on the G.W.R., have proved a failure because of their rigidity.

I could bring forward a great many instances of failures of rigid roads, as I have tried a great many patent metal contrivances for permanent way, but have already taken up too much valuable space. F. J. P.

SIR,—Although "there is not the least likelihood that railway companies will make any change whatever in the methods of construction"—as stated in your leading article of the 1st inst.—I take it that this implies, not an absolute bar to all future progress, but only that the type of track consisting of bull-headed rails in chairs supported by transverse sleepers is now firmly established.

From the time when the correspondence in your columns commenced with my letter, published in THE ENGINEER of October 11th last, I have consistently maintained that this type is the best, not only for the heavy lines of this country, but for railways both heavy and light in all parts of the world; and further, that modern English practice, excepting the matter of sleepers and ballast, leaves little to be desired.

I suppose that a sense of proportion is especially necessary in engineering; but when it is remembered that, whilst the weight and stiffness of rails have been greatly increased within the last thirty years, we are still using sleepers of identically the same pattern as was common before the beginning of the period, some want of due proportion may be inferred. It is true that some railways have adopted a 14in. by 7in. sleeper; but other railways, with faster traffic, retain the 10in. by 5in. section with about one quarter the stiffness, and it is difficult to believe that both are right.

Then, as to the material itself, the elasticity of sleepers of the same size, and the same kind of wood, varies more than 50 per cent., as shown by direct experiment; and as the rails and sleepers have to work together, it seems hard on the former to have such unreliable partners. One of your correspondents has asked what we should think of cast iron rails now. Some time hence a similar question will be asked concerning wooden sleepers.

I suggest that the whole of the parts and materials comprised in a railway track ought to have some rational correlation to each other, both in quality and design, and that this is not the case at present. Moreover, the tendency is still to aggravate the disproportion by further increasing the stiffness of the rail without reference to the sleepers, which ought to be improved, *pari passu*, with the rails.

The early fathers of railway engineering used wood for sleepers, as well as bridges, because they had no knowledge of steel as it is known now, with its almost infinite adaptability to different requirements, and its low cost. The arguments I have advanced in your columns in favour of steel sleepers, regarding both efficiency and economy, have not been refuted, and steel sleepers have not yet received a fair trial in this country. Those used have been made of uniform section throughout, thus imitating the wood sleeper in one of its essential disadvantages; they have been laid in the most unsuitable ballast; and last, but not least, the means of attachment of the bull-headed rails to the steel sleepers have been far from perfect.

The admitted excellence of English track is only secured by an extravagant outlay on maintenance, and a constant vigilance, the least relaxation of which may, as we know, lead to disaster. It is to improvements in sleepers and ballast that attention should now be directed, and I hope that the discussion in your columns may result in more consideration being granted to the substructure of the track, with advantage to both the railway companies and their clients.

JAMES WHITESTONE.

113, Queen Victoria-street, E.C., May 5th.

THE ORIGIN OF THE BESSEMER PROCESS: HOW FACTS ARE MANIPULATED.

SIR,—It will be within the recollection of your readers that in my reply to the statement made by Mr. J. D. Weeks to the American Institute of Mining Engineers—in which he claims for a Mr. Wm. Kelly the originality of the Bessemer process—that I pointed out the fact that one of his witnesses, Mr. John E. Fry, gave us very minute details of the preliminary stages of Kelly's process, even to describing the kind of trolley on which the ladle of metal was conveyed to the apparatus, and how the metal was "dumped" into the open furnace, across the top of which pieces of sheet iron were laid to prevent the sparks flying too freely. I then went on to say, "And here the evidence stops short, for it is clearly not worth their while to pursue the subject any further, it would be dangerous to do so—it would, in fact, 'let the cat out of the bag.' These discreet witnesses have given all the very interesting details as to the 'dumping' in of the molten iron, even to the kind of 'little hauling car' which conveyed the metal to the apparatus; but it would have been infinitely more to the purpose if they had told us something about the way in which this metal was taken out, in what state of partial or complete solidity was it obtained, and whether it was soft malleable iron or hard and brittle 'plate metal.' They have told us nothing of the use of ingot moulds, in which the malleable iron must be made into ingots; they have told us nothing of the treatment of the metal after it was blown. Was it taken to the puddling furnace to be there converted into wrought iron, or was it rolled into bars or sheets from ingots formed while in a fluid state? Without all these essential facts, all their testimony and affidavits are worse than waste paper, as they directly prove nothing; but the absence of these facts affords very strong circumstantial evidence that Kelly never had produced homogeneous malleable iron, and had never made an ingot by his process."

Now it appears that Mr. Fry was not guilty of this suppression of facts, for in a two hours' conversation with Mr. Weeks, Mr. Fry states that he gave him vivid personal recollections antagonistic to his views, and the drawing he supplied proved that as late as the year 1858—two years after Bessemer's patent—"Mr. Kelly's experiments and ideas had not progressed beyond the operations of the finery fire."

The letter accompanying these remarks shows that Mr. Fry was not guilty of this suppression of important facts, which went to show that up to 1858—two years after my patent—Kelly's experiments had not progressed beyond the operations of the "finery fire." Mr. Fry also gave Mr. Weeks an article published in the year 1894, in the *Johnstown Daily Democrat*, written by Mr. Fry, and which he says, "gave what I believe to be the very first public announcement of Mr. Kelly's absolute failure to accomplish anything that could give ground to his claim of being the inventor of the pneumatic process of converting cast iron into its malleable products."

It is, then, not Mr. Fry who was guilty of this wholesale suppression of the truth, of which he says Mr. Weeks had full knowledge, and which he had derived from sources chosen by himself.

The honourable and disinterested love of truth and fair play which has prompted Mr. Fry to send me the following account of his long interview with Mr. Weeks, shows how worthily Mr. Fry has risen from the ranks to the honourable position of manager of the great Cambrian Steel Works.

HENRY BESSEMER.

5417, Penn Avenue, Pittsburg, Pa., U.S.A.,
April 20th, 1896.

Sir Henry Bessemer, London, England.

Esteemed Sir,—Your letter to the technical press of England, in reply to Joseph D. Weeks' address to the Am. Inst. Mining Engineers in session at this city in February last, has been read by me as published in the London ENGINEER of 20th ult. I have no desire to take part in the controversy which naturally follows a resurrection of this long buried question of priority of invention of the Bessemer process, but only share the desire of all fair-minded persons that facts, rather than personal prejudices and interests, may be made matters of history.

In your letter referred to above, you re-quote a quotation by Mr. Weeks, which he credits to an interview he had with me a few days prior to the delivery of his address to the Institute. Your reference to the quotation indicates that it ended abruptly because I, one of Mr. Weeks' witnesses, had something to suppress as to the outcome of the experiment, which would not be favourable to the views of Mr. Weeks as to the late William Kelly's claims to the invention in discussion. It is to advise you that the suppression was by Mr. Weeks, and not by me, that I now recite to you the facts of the interview referred to, and others germane to the discussion.

While Mr. Weeks was preparing his address he sought data by application to Mr. John Fritz, who was General Superintendent of the Cambria Works, at Johnstown, Pa., at the time Mr. Kelly went there to conduct his experiments. Mr. Fritz had no recollection of the events relative thereto, beyond having detailed me to assist Mr. Kelly in every way by assembling such materials as he required and to collaborate with him in his experimental work. Mr. Fritz therefore referred Mr. Weeks to me for data of Mr. Kelly's experiments. At Mr. Weeks' request I called at his publication office in this city, and the interview lasted two hours. During this time I gave him my quite clear recollection of what Mr. Kelly tried to do, what he did, and what he failed to accomplish which he hoped to do. Also I gave him a drawing, made by one of our shop hands at the time, of Mr. Kelly's apparatus of year 1858, which drawing Mr. Weeks designs having engraved for future publication, if it can be made to fit his side of the discussion, which I believe it will not. Moreover, I gave him a copy of a publication issued in Johnstown, Pa., in the autumn of 1894, in which was printed an article written at that time by me under caption of "The Bessemer Industry, Johnstown's Contribution to it."

My interview with Mr. Weeks gave him vivid personal recollections antagonistic to his views. The drawing proved that as late as the year 1858 Mr. Kelly's experiments and ideas had not progressed beyond the operations of the "finery fire," and the printed article gave what I believe to be the very first public announcement of Mr. Kelly's absolute failure to accomplish anything that would give ground to his claim of being the inventor of the pneumatic process of converting cast iron into its malleable products, or in substantiation of the rather vague claim allowed him in his first patent, issued subsequent to the issue of yours in this country.

Now, with this presumably trustworthy testimony at his disposal, Mr Weeks suppressed all except the insignificant extract he quoted relative to Kelly's first apparatus at the Cambria Works, and which you very properly characterised as incomplete reference to the first Kelly experiments there.

On October 24th, 1894, I mailed to you a copy of the Johnstown publication above referred to containing my article which must have miscarried in the post or you would have known that my views were diametrically opposed to those of Mr. Weeks, for in it I made as plain as circumstances would warrant that Mr. Kelly was copying your methods as fully as his limited sources of information enabled him to do, and that he was doing only that. I herewith enclose the folio of the Johnstown publication referred to containing my article, and it should convince you that I am not "one of Mr. Weeks' discreet witnesses" your letter to the press assumes me to be in the sense that I wilfully suppressed the fact of Mr. Kelly's absolute failure in his experimentation at Cambria Works.

In justice to myself I beg to inform you upon what grounds I presume to be considered a competent commentator in reference to the matter in question. I worked with Mr. Kelly, first and last, at the Cambria experiments. I am the chief living witness of his work, and the person to whom he freely confided his hopes of success and fears of failure. Later, beginning in 1871, I worked and studied assiduously for the development of the process, then practically in its infancy in this country. The Cambria Works made such progress in those days as astonished the world. In 1877 A. L. Holley, R. W. Hunt, of the Troy, N.Y., Works, and R. W. Jones, of the—Carnegie—Edgar Thomson Works, united their efforts to induce me to limit the output of the Cambria Works to the product of that time, on the ground that "further quantitative progress would congest the market for steel and ruin the business." Needless to say the proposition was declined, nor that they all experienced a change of view of the market later on. I was manager of the Cambria Steel Works at this time and during the years prior to 1882, when they were producing more Bessemer steel than any plant of similar converter capacity in the world. I have been a leading exponent of the process here in its encroachment upon the field of the open-hearth in the manufacture of special steels, and especially in sustaining it against the assertion of many notable authorities that "its irregularity of physical behaviour unfitted it for structural work." The steel in the superstructure of the Brooklyn Bridge—East River, N.Y.—made at Cambria was a sufficient answer to such. I have been in close touch with the process up to to-day in its most advanced development, and these experiences, with a keen recollection of events, should qualify me as a fairly trustworthy witness. All my friends know me as such and as a frank one.

Mr. Weeks took advantage of me in his misuse of the short quotation referred to. This was misleading to you, as to others, hence your intimation of my holding opinions prejudicial to the facts and consistent with Mr. Weeks' argument adulatory of Mr. Kelly. Naturally I feel that your reference to me as a biassed witness is an unmerited reproach. If almost a lifetime of service to employers faithfully performed, does not entitle me to a reputation for honesty and integrity of expression, then I have lived and laboured in vain.

Respectful consideration for the memory of those who have passed away demands as considerate reference to their achievements as words at command will give expression. It is beautiful and dutiful to only speak kindly of the dead. In the accompanying article I have kept these considerations in view.

The question as to whom the credit of the invention of the pneumatic process is due has, in my opinion as in yours, been settled in your favour beyond controversy. It seems ghoulish work to resurrect it now, after its forty years of sepulture, in any effort to advance undeserving interest. In my humble opinion, Mr. Weeks, as the President of the Am. Inst. Mining Engineers, made an impolitic choice of subject for his address, especially considering the material at his command represented in this city by manufacturing establishments in sight and hearing of his distinguished audience.

I know that it is one of the careless ways of a selfish world that credit is not only not given when due, but is too frequently withheld, and misconferred. A consciousness of duty well done to our fellow men must be the compensation in such instances. But only pure selfishness prompts the theft of others' achievement. Needless to add that pure selfishness is not a rarity, and few live to maturity who do not experience its adverse influences.—Respectfully yours, JOHN E. FRY.

HORSELESS CARRIAGES.

SIR,—As to my mind the purpose of mechanically-propelled vehicles is more or less to supersede the use of horses on common roads, it seems to me absurd that one locomotive vehicle is to be prohibited from drawing another.

It is almost a necessity in every country establishment to have half a dozen different carriages for the various requirements of every-day life, but it would be absurd to have a different pair of horses set apart for each, though this is apparently what will be required of persons employing mechanical instead of animal traction, if the Locomotives on Highways Bill now before Parliament is passed in an unamended form.

The locomotives must necessarily be expensive, and half a dozen will be quite beyond the means of the average private individual, in which case it will be necessary for him to keep up the usual stable of horses, in addition to whatever type of "autocar" he might choose to select.

My idea would be to keep one, or at most two, light locomotives capable of being attached to the present form of carriage. The most simple way of doing so would, to my mind, be to remove the forewheels and lock of an ordinary four-wheeled carriage and drop the pivot socket on to a hook in rear of the locomotive, in the same way that the trail of a field-gun is attached to its limber. In this way the whole length of carriage and locomotive would certainly not exceed that of a carriage and its pair of horses.

It would, I think, be much more reasonable to limit the length of the locomotive and its charge—or locomotive alone — to, say, 20ft. than to make it a hard-and-fast rule that no two vehicles are to be attached together, which prohibition would inevitably lead to much inconvenience. There may be difficulties in my suggestion which I have not foreseen; still, I feel certain that the clause referred to ought to be amended in some way or other, as otherwise the benefits of your enterprise in assisting the promotion of the Bill will be very much impaired.

May 3rd. A COUNTRY GENTLEMAN.

ELECTRICAL COLONISATION.

SIR,—I am indebted to "Rural" for bringing the proposal of Earl Russell and Mr. B. H. Thwaite, C.E., under notice. I find that the article referred to by "Rural" is in volume xx., 189-23, of the *National Review*, under the title of "Electricity in Country Houses." After very carefully perusing the article, and I may add with much interest, I fail to discover how the proposal contained therein affects the novelty of my scheme of electrical colonisation; in fact, although the object aimed at in both proposals is analogous, yet the proposed schemes are of an opposite character.

The proposal of Earl Russell and Mr. Thwaite is explained by the following extracts from the above article:—"The Lauffen-Frankfort demonstration proves that, by co-operation, residents in the country within an area comprised in a circle of from ten to fifteen miles may have in each house the modern resources of electricity at their service. It has been shown that electrical energy can be transmitted over a distance of 110 miles with a loss of only some 28 per cent. For the longest distance in a fifteen miles area, there would be only about one-seventh of the loss. Our proposal is that the owners of country houses should combine for the purpose of establishing at some fixed place—say near a railway station—a station at which to generate the force. At the station a steam engine, or a fuel gas engine, would drive two alternating dynamo machines. The pressure of the current would be reduced at each house to the measure appropriate to the character of the work to be done."

My electrical colonisation proposal is to group, say, a dozen residences adjacent to a central tower; the latter to contain three tanks or reservoirs, which may be designated the storage, distribution, and discharge tanks; the storage tank to be elevated a considerable height above the top of the residences, and may be charged from public domestic supply main, or from natural head, or the water may be pumped into it. The head of water from this tank is available for working water motors driving dynamos for the generation of electricity for lighting, heating, and motive power purposes in the residences, the motor dynamos to be fixed above the top of the discharge tank, the exhaust water flowing into same. The discharge tank to be elevated a few feet above the level of the ground floor, for supplying the lower portion of the residences with water for domestic purposes.

The distribution tank to be at an elevation about level with the top of the residences; this tank can be charged with water from the discharge tank with an electrically driven centrifugal pump, and is available for supplying the upper portion of the residences with water. The storage tank is available for extinguishing fires in the residences. The residences are to be specially designed for electrical equipment; not only is it intended for the lighting and cooking to be effected electrically, but fire grates and chimneys will be substituted with radiators, and the main staircase would be superseded with a simple screwed electric ram lift; a light line shaft, motor driven, to be provided for operating the washing and cleaning appliances for reducing physical exertion.

In suburban districts of most cities and towns the public supply main has a pressure of from 15 lb. to 40 lb. per square inch, and this source of energy is mostly wasted, excepting in the case of high buildings and elevated districts. Now with my scheme the storage tank can be charged direct through the meter, and the head of water is then available for generating electricity at an efficiency of at least 70 per cent., and the water is still available for domestic use. The storage tank dispenses with the need of storage batteries, and is available for giving a large quantity of power as required at intervals, the charging going on continuously. This system requires the minimum of attention, is noiseless in working, and has no waste products. Of course in districts where supply mains do not exist, a pumping plant could be adopted to charge the storage tank, and even then the arrangement would be comparatively economical and convenient.

From a public supply main, with an average meter charge of 8d. per 1000 gallons, electricity could be generated for less than 2d. per unit, and the water still be available for domestic purposes. My proposal is for one ownership to possess the colony, and to let the residences upon defined terms; the tenants would pay rent and electricity charges in lieu of rent, coal, gas, and water rates in ordinary residences. This system would facilitate the use of horseless carriages electrically propelled, which could be charged at periods when the demand for electricity is low for domestic purposes.

Now I should like to ask "Rural" where does the idea of colonisation come in the proposal he refers to? To colonise is to create, plant, or establish, and that is the essential feature of my scheme of electrical colonisation, whereas the proposal he refers to is one of provision only, having for its object the providing of electricity to country houses, and the scheme if worked out would resolve itself into a public supply scheme as established in many cities and towns, and many would be the difficulties to surmount in obtaining provisional orders for the distribution cables, and in getting the majority of property owners to share the responsibility of the undertaking. My proposal removes all these difficulties, and narrows the scheme to simply a matter of tenancy under defined conditions of a fixed rent and minimum charge for electricity, with meter registration for maximum quantity of current used.

The statement of "Rural" in questioning the novelty of my proposal of electrical colonisation cannot be substantiated from the source to which he has referred.

THOMAS MEACOCK.

Birmingham, May 5th.

ROLLED STEEL v. CAST IRON CHAIRS FOR RAILWAYS.

SIR,—It does not often fall to the lot of a correspondent to evoke such unanimous expression of opinion regarding the merit of a question as to give birth to a leaderette, for which I feel highly flattered, and so are the platelayers.

This emboldens me to again address you. You, Sir, hold that "It is mainly a question of expense." I have made inquiries which enable me to assert, positively, that the first cost of the new patent rolled steel chair for main line will effect a saving of 3d. per chair, which on a mile of railway means 8000 chairs and represents £100. It is not too much to expect that the life of the steel chair will be more than double that of the cast iron one. Those in authority who have gone into the question will be able to say whether my assertions are well founded. Many other advantages are apparent to your readers in favour of the steel chair, which I need not further refer to.

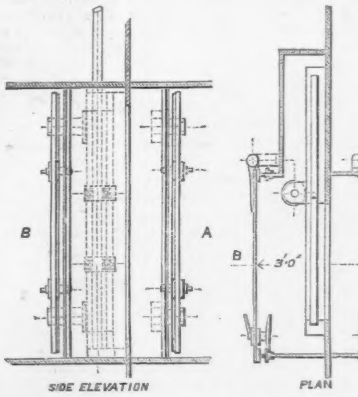
FOR THE PLATELAYERS.

Langside, Glasgow, May 4th.

WATER-TIGHT DOORS IN THE NAVY.

SIR,—As an outcome of the recent discussion on water-tight doors by the Institution of Naval Architects, and as water-tight doors often do not answer the purpose for which they are designed the accompanying sketch will illustrate what I would propose to fit below the water-line to more surely effect the keeping afloat a ship after one compartment has filled from collision, or otherwise.

Supposing the compartment on the right-hand side of sketch were full of water, door A would act, the pressure of water tending to keep the door shut and tight; if the compartment on the left, and supposing it to be the fore compartment of a ship, door B would act in the same way. It might be objected that the proposal involves the absorption of too much of the ship's space, but considering the number of lives at stake, it is worth the sacrifice. All the doors might be left open when there was comparatively little danger, but at night, when manœvering, or in fog, the hinged doors might be closed without fastening, being hung slightly inclined from the vertical so as to keep closed, but still allowing free passage for the ship's company, then in case of collision there would be plenty of time to close the main horizontal sliding doors.



Devonport. CHAS. W. ROWE.

CIRCULATION IN WATER-TUBE BOILERS.

SIR,—As I notice that the correspondence on the "Circulation in Water-tube Boilers" still continues, will you allow me to point out that the form of the ends or orifices of the water-tubes has a material influence on the circulation. To this fact attention has, I believe, not yet been drawn in the recent letters which have appeared. With the Yarrow boiler it has been the invariable practice to bell-mouth the upper and lower ends of the tubes. This is no doubt desirable in this type of boiler for purposes of strength; but experiments have shown conclusively that this bell-mouthing has a very marked effect in increasing the circulation, as all who are conversant with the laws governing the flow of water through pipes would expect.

F. W. CROHN.

14, Burney-street, Greenwich, May 4th.

LIQUEFACTION OF GASES.

SIR,—"Zero" kindly offers to give "Cryos" any information he can. Perhaps he will kindly tell us (1) how soon after starting the apparatus the gases begin to liquefy. (2) How much of the gas that is compressed, say per stroke, is liquefied during the time occupied by the same stroke. (3) At what temperature is the gas when it returns from the apparatus to the compressing cylinder say, the temperature on leaving the apparatus, and the temperature just before re-entering the compressing cylinder.

TO CORRESPONDENTS.

Registered Telegraphic Address, "ENGINEER NEWSPAPER, LONDON."

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* THE ENGINEER, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

A. A. W. (Norwood).—*It would be illegal to run a steam omnibus as you suggest between Anerley Station and the Crystal Palace. Inside the grounds the Palace Company may do as it pleases, but not outside.*

STUDENT.—*The stresses remain of the same size when the tie beam carries a floor, but the beam will be subject also to stresses as a beam between each of the supports and the vertical ties and queen posts. You will find your questions answered in any of the elementary books on roof trusses and girders, as, for instance, in Adams' handy book on stresses. See Molesworth's Pocket-book.*

DR. ANGUS SMITH'S COATING FOR PIPES.—*According to Mr. B. H. Thwaite, Dr. Angus Smith's method of protecting iron is most successful if effected as follows:—The ingredients consist of coal tar and pitch oil in the proportions of one part tar to three of oil. The mixture being heated to the boiling temperature of the oil, the castings are then immersed in the mixture, and allowed to remain in it until the same temperature is diffused throughout the mass. The castings are then gently withdrawn, the naphtha and other volatile oils evaporating and drawing off the castings, so that whilst still very hot, a firm, hard coating of pitch is left, which firmly adheres to the casting. Care should be taken to heat the mixture to a proper degree, viz., 350 deg. to 450 deg. Fah. If it is too hot the pitch will be overheated, and afterwards scale off. The castings should be newly from the sand, clean, and not rusty, or if rusty must be well scraped, and completely cleared of any rust coating. For description of the method see "Pipe Founding," by J. W. Macfarlane. London: E. and F. N. Spon.*

MACHINERY FOR MAKING UMBRELLA PARTS, HORN, IVORY, AND METAL BUTTONS, AND STEEL PENS.

(*To the Editor of The Engineer.*)

SIR,—We shall esteem it a favour if any of your readers can give us the names of manufacturers of machinery for the manufacture of (1) umbrella parts; (2) horn, ivory, and metal buttons; (2) steel pens.

London, April 30th. J. H. H.

BOOKS ON RAILWAY SIGNALS.

(*To the Editor of The Engineer.*)

SIR,—With reference to the letter from "J. V. P.," appearing in your issue of the 24th ult., I beg leave to say that I have now in the press a work on "Railway Signalling." The book deals with every branch of signalling, contains nearly 500 illustrations, and will, I think, be considered complete. It will be issued during the present summer.

L. and Y. Ry., Manchester, May 5th. H. RAYNAR WILSON.

METAL PLATES COVERED WITH LINOLEUM OR THE LIKE, AND FURNITURE WITHOUT WOOD.

(*To the Editor of The Engineer.*)

SIR,—I understand that plates or sheets can now be obtained suitable for panels or other such purposes covered with linoleum, Lincrusta Walton, or other such material; and also that some furniture suitable for use on board ship is now made without wood. Can any reader give me the names of the manufacturers of either of these and oblige? C. D. G. S.

May, 1896.

BAGULEY'S LOCOMOTIVE ENGINE.

(*To the Editor of The Engineer.*)

SIR,—Referring to my letter in last week's issue, the locomotive is described as a compound. Such is not the case, it having two inside cylinders 22in. diameter by 30in. stroke, not a 22in. and a 30in. cylinder.

ERNEST E. BAGULEY.

Castle Engine Works, Stafford, May 5th.

SUBSCRIPTIONS.

he ENGINEER *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

Half-yearly (including double number)	*£0 14s. 6d.*
Yearly (including two double numbers)	*£1 9s. 0d.*

If credit occur, an extra charge of two shillings and sixpence per annum will be made. THE ENGINEER *is registered for transmission abroad.*

A complete set of THE ENGINEER *can be had on application.*

In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates, will receive THE ENGINEER *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

THIN PAPER COPIES—	
Half-yearly	*£0 18s. 0d.*
Yearly	*£1 16s. 0d.*
THICK PAPER COPIES—	
Half-yearly	*£1 0s. 3d.*
Yearly	*£2 0s. 6d.*

READING CASES.—*The Publisher has in stock reading cases which will hold thirteen copies of* THE ENGINEER. *Price 2s. 6d. each.*

ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.

Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.

Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of THE ENGINEER.

MEETINGS NEXT WEEK.

THE INSTITUTION OF ELECTRICAL ENGINEERS.—Thursday, May 14th, at 8 p.m. Paper: "The Influence of the Shape of the applied Potential Difference Wave on the Iron Losses in Transformers," by Stanley Beeton, C. Perry Taylor, and J. M. Barr, students.

THE INSTITUTION OF CIVIL ENGINEERS. — Tuesday, May 12th, at 8 p.m. Papers to be discussed: "American and English Methods of Manufacturing Steel Plates," by Mr. Jeremiah Head, M. Inst. C.E. "Four American Rolling Mills," by Mr. Samuel T. Wellman.

ROYAL INSTITUTION OF GREAT BRITAIN.—Tuesday, May 12th, at 3 p.m. Lectures: "Ripples in Air and on Water," by C. V. Boys, F.R.S A.R.S.M., M.R.I. Thursday, May 14th.—"The Art of Working Metals in Japan," by W. Gowland, F.C.S., F.S.A. Friday, May 15th. Discourse: "Cable Laying on the Amazon River," by Alexander Siemens, M. Inst. C.E., M.R.I. Saturday, May 16th, at 3 p.m.—Lecture: "Three Emotional Composers," by F. Corder, Curator, Royal Academy of Music.

DEATHS.

On the 29th April, at Montague Mansions, Great Russell-street, London' PETER JOHN MARGARY, M.I.C.E., aged seventy-five.

"THE ENGINEER"
ROAD CARRIAGE COMPETITION.

FOR the protection of intending competitors at our trials of Horseless Carriages, we have made application to the Board of Trade for its certificate under the Patents, &c., Act, 1883. Our request has been granted, and the following certificate and extracts from the Statute speak for themselves:—

PATENTS, DESIGNS, AND TRADE MARKS ACT, 1883.

Upon the application of Mr. Sydney White, Publisher of THE ENGINEER, 33, Norfolk-street, Strand, W.C., made to the Board of Trade on the 22nd day of April, 1896, the Board of Trade do hereby certify that the Exhibition proposed to be held in the year 1896 at the Crystal Palace, Sydenham, in connection with THE ENGINEER Road Carriage Competition, is an Industrial Exhibition.

Signed by order of the Board of Trade this 29th day of April, 1896.

FRANCIS J. S. HOPWOOD,
Assistant Secretary Board of Trade.

The following are the sections of the Act referred to:—

PART II.—PATENTS: *Exhibition at industrial or international exhibition not to prejudice patent rights.*

Section 39.—The exhibition of an invention at an industrial or international exhibition, certified as such by the Board of Trade, or the publication of any description of the invention during the period of the holding of the exhibition, or the use of the invention for the purpose of the exhibition in the place where the exhibition is held, or the use of the invention during the period of the holding of the exhibition by any person elsewhere, without the privity or consent of the inventor, shall not prejudice the right of the inventor or his legal personal representative to apply for and obtain provisional protection and a patent in respect of the invention or the validity of any patent granted on the application, provided that both the following conditions are complied with, viz.:—

(*a*) The exhibitor must, before exhibiting the invention, give the Comptroller the prescribed notice of his intention to do so; and

(*b*) The application for a patent must be made before or within six months from the date of the opening of the exhibition.

PART III.—DESIGNS: *Exhibition at industrial or international exhibition not to prevent or invalidate registration.*

Section 57.—The exhibition at an industrial or international exhibition, certified as such by the Board of Trade, or the exhibition elsewhere during the period of the holding of the exhibition, without the privity or consent of the proprietor of a design, or of any article to which a design is applied, or the publication during the holding of any such exhibition, of a description of a design, shall not prevent the design from being registered, or invalidate the registration thereof, provided that both the following conditions are complied with, viz.:—

(*a*) The exhibitor must, before exhibiting the design or article, or publishing a description of the design, give the Comptroller the prescribed notice of his intention to do so; and

(*b*) The application for registration must be made before or within six months from the date of the opening of the exhibition.

THE ENGINEER.

MAY 8, 1896.

THE FIRE-BOXES OF LOCOMOTIVE ENGINES.

THE adoption of the Belpaire fire-box by Mr. Harry Pollitt in the engine we illustrated on the 20th of March and some thirty similar locomotives, has excited some attention and drawn forth some comment. The Belpaire box is extensively used on the Continent, and very little anywhere else. The M. S. and L. engine does not furnish the first instance of its use in Great Britain; but it has found scant favour in this country. The title is, however, used in a somewhat loose way. Any flat-topped external fire-box is called by the name; but the original Belpaire box was used with a special fire grate, and had its origin in the necessity for burning small, or slack, coal. Belgian locomotives have the largest grates in the world. Grates 10ft. long and 7ft. wide are not unknown, and grates 8ft. by 6ft. are almost common. The difficulty of supporting the enormous crown plate is apparent, although the precise figures are seldom stated, or the magnitude of the strains realised. The total load on a fire-box crown, with an area of 70 square feet and a pressure of 150 lb., is 675 tons. The crown of the fire-box of an English locomotive will have to carry only about one-third of this amount. To support the crown of the Belgian fire-box with bridge stays is out of the question, and even if it could be done, the top of the outer fire-box bent to a cylindrical curve being about 8ft. in diameter, would rise to a point higher than the tops of the coaches in the train. To meet the conditions nothing remained but to make the tops of the inner and outer fire-boxes flat, and to tie them together. The locomotive boilers in torpedo boats are always made in this way in order to save at least two tons in crownbars, and to keep the top of the boiler low.

Locomotive superintendents know by bitter experience that the boiler is *the* weak part in their rolling stock. The engines do not wear out; the wear and tear of tires is comparatively trifling; frames seldom break; when the permanent way is reasonably good the outlay on the renewal of springs is small. But from the moment the boiler is first used to the moment when it is relegated to the scrap heap it costs money for repairs and renewals. It is a never failing source of worry and expense, and the worst part of it all is the internal fire-box. If that gives way in no other place, then the mere friction of the fuel against the side plates cuts the heads off the screwed stays and wears the metal thin. All the rest of a locomotive may remain excellent for twenty years. That must be a good boiler, or one very lightly worked, that does not need careful overhauling and considerable repairs after being in use three years and making some 55,000 or 60,000 miles. We have, of course, all met with exceptional boilers, but that must not be taken to represent the rank and file of a great railway system. It is in no way remarkable that engineers should examine every method of construction and criticise its weak points with care. Now, one of the worst points about the ordinary fire-box is the tendency to break side stays. The inside box being of copper, and hotter than the outside box of steel a less expansive metal, rises and falls with each change of temperature, and bends the side stays up and down, so at last they break. To combat this tendency to break, attempts have been made to give a certain amount of elasticity. In some cases the stay bolt has a hole drilled through it to reduce its sectional area. The inner end of the hole is plugged. If the stay breaks water will rush out through the hole and tell the tale, so that drilling is useful in two ways. Another plan consists in turning down the middle of the length of the stay. This sometimes causes trouble in putting the stay into its place. On one English line will be found a very ingenious machine which reduces the middle of the stay for a couple of inches of its length, but not to such an extent as quite to obliterate the thread. The stay can, therefore, be put in place without trouble, while there is sufficient reduction of area provided greatly to prolong its life. When we come to the method of carrying the crown of the box, we find that in this country almost invariably bridge stays are used. These stays ought to go across the box, because when they are bedded on the top edge of the tube plate they tend to force it down and make the tube holes oval. We have seen a copper plate distorted in this way to a surprising extent. It is the old story of the flow of solids. When the bridges are put on longitudinally, as they often are for structural convenience in fitting longitudinal stays, the regulator gear, &c., sling stays are used to support and help the bridge stays, and save the tube plate. These sling stays require to be fitted with very great care, and we confess that we do not regard them with any favour. The external box being curved to a circular arc, cannot rise and fall in the least, and no matter how tightly the slings are screwed or keyed up when the boiler is cold, they must be slack when it is hot, because of the rise of the fire-box. We have heard engineers admit this, and yet use the slings, as they said, as a measure of precaution, less a bridge should break. On the other hand, it must be admitted that a bridge stay is not free from serious objections. No matter how carefully bedding at the ends is effected, there is a tendency to squeeze down and injure the side plate. Besides, the whole load and stress are thrown on the foundation ring and its rivets, and we would willingly spare the ring a burthen of 200 tons or so if we could. The weight of a set of bridge stays is by no means insignificant, but as it serves in many cases to help in distributing the load on the wheels, this is of small importance. We need only mention, in passing, that the presence of bridge stays does not facilitate the cleaning of the fire-box crown. But they are not, perhaps, worse in this respect than other methods of staying.

In the Belpaire box there are no bridge stays, the flat tops of the two boxes being secured to each other by screwed stays ⅞in. or ¾in. in diameter, just the same in all respects as the side stays, save that they are four or five times as long. The objection brought to bear against this method of construction is that the rise of the internal fire-box slacks the stays, or, more strictly, tends to slack them, and that the crown plate is in consequence bent down and distorted. We hold that this objection is quite untenable. The flat crown plate of the outside fire-box is much larger than the inside plate, and is therefore more flexible. Obviously both plates are so flexible that, under pressure, the stays are fully loaded. The rise due to the greater expansion of the inner box is in great measure compensated for by greater depth of the outer box, and this is especially true of the Belpaire boxes, which are very shallow, although the steam space remains about the same, no matter what the depth of the box. It may be urged, of course, that the sling stays expand down as much in proportion as the outer sides rise. Taken altogether, however, we believe that in practice it will be found that the flat top of the outer box rises a little when the engine is under steam, and that the inner box does not drop, or undergo any distortion. The danger of distortion is, of course, that it may bring about the cracking of the crown plate, especially near the sides. The risk is, of course, transferred to the outer plate, but we believe that it exists much more in theory than in fact. We have not heard that the crown plates of Belpaire boxes are more liable to crack than are the side plates of normal fire-boxes.

Having said so much in favour of the Belpaire box, we may go on to add that we have no intention of urging that it is better than the usual English box with bridge crown stays. Either makes a fairly good job; which will be found the better depends on many circumstances, and above all on the size of the grate. The bigger the grate the stronger are the arguments in favour of the Belpaire box. The test of merit is very narrow. The first cost seems to be about the same, or perhaps a little in favour of Belpaire. For the rest, failure will take place, if at all, by the breaking of the stays and the cracking of either the inside or outside crown plate or both. We see no reason to think that either method of construction is distinctly and prominently better than the other in this respect. Probably some of our readers can supply information on this point derived from experience with both methods of construction used under similar or nearly similar conditions.

EDUCATION AND INVENTION.

WE commend to the attention of our readers the final paragraphs in the admirable address of the newly-elected President of the Institution of Mechanical Engineers. No man is in a better position to say what technical education can and can not do for this nation than is Mr. Windsor Richards. Those who see in education a panacea for all commercial ills, never stop to ask themselves whether there is any other side to the glowing picture they delight in drawing. Is it not possible to have just too much education and yet not enough? Not long since a correspondent advanced in our pages a sufficiently remarkable proposition. Writing about Dr. Hampson's process for the production of liquid gases, he said that apparatus of the kind could not be invented by men of strict scientific training. These were not "Zero's" precise words, but his longer statement only developes a little the same idea. At first sight the proposition appears to involve a paradox, but only at first sight; and although we cannot go so far as "Zero," we have little difficulty in admitting that there is a large substratum of truth in his assertion. The Hampson or Linde process is apparently thermodynamically wrong. No one rigidly trained in the thermodynamics of the text-books would think in the particular way necessary for the evolution of the Hampson apparatus. That is "Zero's" argument, and it would not be easy, even were we disposed to make the effort—which we are not—to refute it.

It is a noteworthy fact that the most important inventions have sprung from the brains of men who possessed very little precise scientific education; and it is almost equally true that such an education has never done much to develope, or aid the development, of any invention. It is, of course, an old story, that professors never invent anything worth having. It is not quite true. We may, however, leave the professors alone; they have work enough to do without inventing. There are multitudes of well-trained scientists and engineers who are not professors, and we may confine our attention to these, and ask how it is that accurate training seems to rob a man of all power of inventing; and how it is that the best things in the world have been produced by men comparatively ignorant. To explain the phenomenon, we must first settle what invention really is; what the word means; what its use involves. Now, we hold that nearly every invention is, in a sense, a discovery. In courts of law, hundreds of thousands of pounds have been expended in deciding what does and does not constitute an invention, what does and does not constitute a discovery. An invention can be patented, a discovery cannot, although the apparatus by which the discovery is made useful in the arts can be patented. Let it be conceded, for the sake of argument for the moment, that the difference between an invention and a discovery is one of degree and not of essence, and we shall be able at once to understand why a rigid and excellent scientific training may stifle invention. Such a training may be, and in mechanics at all events always is, fatal to discovery. It teaches that there is nothing left to discover. Everything is known that can be known for example, about heat, and the steam engine, and so on. If a carefully trained student proposes to himself to accomplish a certain thing in a particular way, his training may tell him that the thing he proposes to do cannot possibly be done, because the doing of it would break one of nature's laws. The result is, of course, that he sits still and does nothing. He bows to the inevitable. Another man, possessing far less knowledge, does not know enough about the subject to prevent him from trying a particular experiment. He tries it and succeeds. Then the learned man finds that he knew too much and yet not enough. The invention is a success; and yet its success involves no infraction of nature's laws. The ignorant man tried an experiment because he was ignorant; the learned man did not because he held that it would be useless to try it. It cannot be disputed that under the circumstances learning did more harm than good. Many illustrations of our meaning will suggest themselves to our readers. For example, let us take the modern bicycle. Any one carefully trained in the principles of equilibrium, and attaching due weight to the proposition that if a line joining the centre of gravity of a body with the earth falls outside the base of the body that body must upset, would say that it was quite ridiculous to suppose that a machine supported on two wheels only in the same plane could possess sufficient stability. We have heard it argued that the old high bicycle could not be mounted without the aid of a bystander, because its instability at slow speed was too great. Again, anyone who was carefully trained in mechanics would reject as preposterous the notion that a wheel could be made with thin wire spokes which would carry a heavy man. Furthermore, there is not a portion of the framing of a bicycle that is not, in the eyes of any one carefully educated in the strength of materials, utterly wrong. If any one of our readers will take the trouble to work out the stresses in a bicycle weighing 28 lb., and carrying at ten miles an hour a man weighing 12 stone, he will see that from first to last the whole machine is so completely impossible that nothing of the kind exists outside the land of dreams. Let us suppose that a law was passed under which no one was permitted to use a bicycle that was not pronounced to be quite safe by the Boardof Trade; and let the surveyors of the Board deal with the cycle precisely on the same lines as they deal with marine boilers, and see then what the Board of Trade machines would be like. Is it too much to say that, twenty years ago, any and every thoroughly trained engineer would have pronounced the modern "light roadster" a mechanical impossibility. Such men would know too much to attempt to produce anything of the kind. Let us take the injector again. To all intents and purposes its action was discovered, not invented; and it was discovered by a man who was in search of what was apparently thermodynamically impossible. The announcement that Giffard was forcing water into a boiler by means of a jet of steam drawn from the same boiler was received by every trained mind with shouts of derision; and months, if not years, elapsed before a theory of the action was formulated or accepted. Again, no trained electrician believed that it was possible to send a number of messages over the same wire at the same time. Edison, the telegraph clerk, did not know it was impossible; he tried and succeeded, and now as many as six messages can be sent at the same time without interference.

There are, however, certain inventions which are not in their nature discoveries at all, they are inventions by courtesy. They involve little more than the combination in a more or less novel form of old and often well-worn thoughts and things. It does not appear to us that any amount of training could hamper useful progress along this line. On the contrary, it may prove of the utmost service. It may prevent the commission of very serious mistakes, and much waste of time and money; and this brings us back to the starting point, and the proposition that a high scientific training is often and in many ways fatal to the exercise or development of inventive genius. Our readers who have followed us so far will see that the reason why lies in a nutshell; it can be stated in very few words. It is simply that knowledge is too often assumed to have reached finality when it has done nothing of the kind, and the belief is fostered and inculcated by those who write books and treatises and teach, in various ways. We are not now speaking of professors only, but of teachers at large, whether in the college or the workshop. Each man is prone to say, "There, read that, or listen to this. There is nothing more to be written or said; I have exhausted the subject, covered the whole ground." A noticeable example is supplied by a very simple device, the "hurdy-gurdy," or Pelton wheel. We have only to take down from our shelves any book on hydraulics published more than ten years ago to learn that an impulse wheel driven by the impinging of a jet of water on its vanes must be extravagantly wasteful of water, yet recent investigations have shown not only that the Pelton wheel is very economical, but that it ought to be so in the nature of things. The man of high science produces the turbine, a very admirable invention; but the Californian miner with practically no training and plenty of water under pressure, proceeding on quite different lines, turns out a machine very much cheaper and simpler, particularly in the matter of installation, and one not less economical in the use of water.

Lastly, we would point out that it is not the possession of knowledge that stops progress; the mischief is done by the assumption that the knowledge is final. In other words, the training becomes too dogmatic—too monkish, if we may use the word. The young man finds it very difficult to believe or to understand that his teacher in the college, or his head in the office, does not know all that is to be known; and it is only human nature that he should subsequently take to himself the belief that he himself knows all about everything, and that if he thinks nothing can be achieved in a certain direction nothing can be achieved. Yet it cannot, we think, be disputed that most of our leading scientific men know a great deal too much to invent anything; and so the world gets its steam, gas, and oil engines; its railways; its high speed ships; its power looms; its spinning jennies; its horseless carriages; its telegraphs, not from the man of science, not from the teacher, but from the hard worker; who is continually trying new things, because he has never learnt that there is a law or a limit beyond which he cannot go. No doubt much time and labour and money are wasted; but in the long run the world owes more to the man who does not believe in the impossible than it does to the man who sees it everywhere.

◆◆◆

THE GERMAN GOVERNMENT AND ENGLISH STEEL FOR SHIPBUILDING.

IT is a complete reversal of the condition of affairs to which attention in this country has lately been so continuously directed to find German steelmasters complaining of competition from England; and it shows that there is a bright side to the foreign competition shield as well as the duller face, to which alone we have been accustomed to gaze for so long a time past. The Association of German Iron and Steel Manufacturers has sent a petition to the German Minister of Public Works, in which that official is urgently requested to reduce the freight rates on shipbuilding material. They say that under existing conditions they are no longer able to compete with the English, and they declare it to have become an absolute fact that most of the vessels built on German soil are produced from English material. This is due to cheaper transporting facilities from England to the German seaports, where most of the shipyards are located, and to the great and consequently cheap production of Great Britain, which still builds 70 per cent. of all the ships in the world. As much as 133,834 tons of iron and steel for ship construction were imported from Great Britain during the period from 1890 to 1895. The German manufacturers announce their intention of establishing a "central bureau" to be entirely devoted to this line of the trade, which is to watch the British prices and to place orders from shipyards with German works that are able to fill such orders in the shortest time possible. We assume this means a ring of shipbuilders who will only accept German tenders. The memorial also contains a table showing some of the lowest offers of German and English work f.o.b. dock at Hamburg so far during 1896. The German average price for the different kinds of iron and steel used in shipbuilding was 117·67 marks, while the English bids averaged only 96·28 marks. For boiler plate, for instance, the lowest German offer was 174·05 marks, while two English works offered them for 119·23 and 138·90 marks respectively. British competition is felt still more severely along the Baltic coast, which is twice as far from the Westphalian iron district as Hamburg. Here it is where the question of railroad rates plays a specially important part. The Vulcan shipyard at Stettin called in 1895 for bids for the supply of material for a fast ocean steamer, and these were the lowest average prices asked:—German works, 136·77 marks; English works, 113·90 marks. In addition to this, the English works conceded 2½ per cent. cash discount, while the Germans would grant only 1½ per cent. The German manufacturers declare their willingness to reduce their price to the lowest figure possible, but say that a little pressure ought to be brought to bear by the German Government on the shipyard owners to induce them gently, but effectively, to use none but German material in the construction of vessels. They believe that they would be able to drive the English from this market if a law could be passed providing that only vessels constructed of German material shall be used in the Imperial service, and if the lowest freight tariff which now applies to coal only would also be granted to material destined for the construction of vessels. As yet, so far as we are aware, the memorial has not produced any practical effect, and we trust it will be a long time before the German Government passes such a law as that petitioned for.

LITERATURE.

Pumps and Pump Motors. By P. R. BJÖRLING. 2 vols. London: E. and F. N. Spon. 1895.

THIS is a large book. The first volume contains 280 quarto pages of text and eighty pages of tables, besides an index; the other volume contains 1006 figures of illustration upon 261 large plates. There is, therefore, a great quantity of matter in this work. It is well classified into divisions. Thus the first part, containing 107 pages, deals with the general forms of pumps, and is illustrated by 388 diagrams. The second part, of forty-six pages and 266 illustrations, is descriptive of the detailed construction of valves; while the third is similarly devoted to buckets, pistons, and plungers, illustrated by 122 diagrams. Air vessels and pump leathers are next dealt with at shorter length, and with the help of forty-three drawings; and next, fifty-nine pages contain descriptions of pump motors, with seventy-one illustrations. This part seems less bulky, in comparison with the others, than the importance of its subject demands. The chapter on steam, gas, and oil pumping engines occupies thirty-four pages, and that on electric driving of pumps thirteen pages. The other parts are entitled, "Charging and Testing Pumps," "Rules and Formulas," and "Tables." In the latter there are thirty-five tables, most of them of an extended arithmetical character.

A comprehensive and thoroughgoing work of sound character upon pumps and their driving engines was greatly needed, this branch of mechanical engineering, perhaps the oldest established in practice, and certainly one of the most important, having been neglected in technical literature to a surprising extent. To a slightly less degree the same is the case as regards hydraulic motors. The appearance of Mr. Björling's large work must, therefore, have been welcomed with sanguine expectations. But it may be at once confessed that its quality is by no means commensurate with its magnitude; so much so that it still leaves the field open for a sounder work, which may be, perhaps, half the size of this and yet contain much more practically useful matter. The descriptions of the constructions shown in the plates are very needlessly prolix and wordy. Often the text corresponding with a drawing is half taken up in statements of the reference numbers of plate and diagram, and the rest in mention by letter name of parts which are seen at the first glance at the drawing by the merest tyro in the knowledge of machinery. This cataloguing of ordinary elementary parts is repeated *ad* *nauseam* through hundreds of examples, and is in the bulk of the cases unrelieved by any criticism, favourable or the reverse, of the specialities peculiar to the design. Too often, beyond the mere letter A B C cataloguing of parts, the only remark made is such as "a very useful little pump," "another very neat type of pump," "a badly, although neat-looking, designed double-acting piston pump." The last quotation is a sample of the sort of grammar found throughout the book; it sometimes gets down to a very hopeless level. It is good to direct attention to details of construction, but to succeed in doing this with any ordinary reader it must be done in an interesting and enlightening fashion. "A is the working barrel, fitted with a piston packed with hemp and tallow, and secured to the piston-rod C by means of double nuts." This sample of description rises above the average, because it indicates the kind of packing used, and also the method of fastening the rod; but after similar statements have been already made regarding fifty other pumps, it cannot be regarded as attractive.

With regard to these details, there are scattered throughout the book very many intelligent and highly useful hints—in fact, it is in suggestions as to small detail points of construction that the greatest merit of the book lies. But to get hold of these, one has to wade through a woeful amount of mere word padding that makes one dizzy by its unusual degree of uninstructiveness.

Again, in a work having this aim, it is an unexceptionally good feature to have abundance and large variety of illustration of practical design, both in general arrangement and in detail. But no useful purpose is served by multiplying illustrations of unimportant and ineffective minute differences of detail, and of fantastic designs which, if they ever saw the light outside the Patent-office, must certainly have suffered immediate extinction as abortions. No doubt the wild excentricity of ignorant and untrained genius—to give it its most generous possible title—has revelled in a freer fashion in the design of pumps than in most other mechanical regions; but the kindest thing to do with the products of these errant imaginations is to let them sleep the slumber that is natural to irregular conceptions. We welcome, however, quite unreservedly the 267 illustrations of pump valves, because this subject of valves is of overwhelming importance in pumping efficiency, and because the diversity of design found in actual construction shows how little and imperfectly the subject is understood in the drawing office. These 267 drawings necessarily contain many proposals that are eminently ridiculous; but in this one direction under present circumstances the observation of all the varieties that have been conceived can hardly be otherwise than instructive to him who is prepared to learn.

As for the style of printing adopted for these drawings, we cannot honestly praise it. Many of the same drawings appear in Mr. Björling's small book on "Pump Construction," published by the same firm, printed in a much clearer and more intelligible manner. We here find special parts of the sections printed in continuous blocks of jet black. These masses of black surface are displeasing, and even painful, to the eye of a trained draughtsman; and as the sections of different parts so treated run into each other without any distinction to show change from one to another metal, or from one to a separate part—without even a dividing line between the parts—the result is distinctly and technically bad drawing.

There remain the more theoretical portions of the work to criticise, those portions dealing with principles, dynamic and other. Here, again, it ought to be mentioned that there lurk in odd corners throughout the pages useful reminders of subsidiary actions that are apt to be overlooked, and which, nevertheless, are important as affecting efficiency. But as regards the main dynamic principles that govern the working of pumps, the teaching of this book is of an order that is more justly characterised as low than as modest; it might also be termed comic if it were not the reverse of amusing and were not evidently intended to be taken seriously. The art of putting rider before horse, and of leaving the horse riderless, and of driving both rider and horse in aimless mazy circles, is cultivated to an extreme extent. The author seems so impressed with the discovery that it is the pressure of the external air that drives the water up and along the suction pipe into the pump barrel, that in one passage he goes the length of saying that the whole work of pumping is done by the atmosphere. He is also under the impression that if all joints in a suction pipe and barrel were perfectly air-tight the water would follow the piston, bucket, or plunger up to a height of 34ft. above the well level. He thus shows himself magnificently indifferent to frictional resistances as dependent on length and size of pipe and on the velocity of flow; to inertia resistances as dependent upon acceleration of velocity, and to evaporation at low pressure. Indeed, towards the end of the volume he explains the action of an air vessel upon the suction to be that the suction pipe delivers into the air vessel the whole of the water required for one delivery stroke of the pump during the delivery stroke; during the suction stroke it runs from the air vessel into the pump barrel, the water in the suction pipe presumably standing stationary meanwhile in an obliging manner to let the other pass. The problem of proportioning a suction air vessel so as to obtain half the pump-full flowing into it during the delivery stroke and flowing again out of it into the barrel during the suction stroke, so as to maintain a constant average velocity throughout both strokes in the suction main is not even suggested anywhere. As it involves calculations of accelerations of momentum and some other things, it may have been beyond the power of the author to solve it; but a suggestion of the existence of such an evidently useful problem might have stimulated the intelligent pump maker to solve it for himself, either by calculation or by experiment. In explaining "pressure" or delivery air vessels, it is said the object is "to prevent concussion," and "to economise the power of the motive force by keeping the liquid in constant motion, thereby decreasing the speed of the liquid when the pump pipes are smaller than the pump barrel." The first part of this statement is unexceptionable, but its effect is quite spoilt by the succeeding explanation. Certainly the maximum, as compared with the average velocity, is decreased by the action of the air vessel, and for frictional reasons it is a good thing to diminish the variation from the average velocity. But this has no relation of any kind to the ratio between pipe and barrel section. Of course the bad effects of variation of velocity in the delivery main are aggravated by relatively small sections of this main; but the air vessel does not diminish the average velocity in any case, and it reduces the ratio of maximum to average just as much if the main be large or small. Most of the remarks in Chapter XXXIV. on the placing of air vessels are well founded; but what can one think of the recommendation to fashion the volume of the air vessel in high and narrow shape, "because there will be a greater thickness or layer of air, hence it will be more elastic." A better reason also given, namely, that the absorption of air on the less surface of water has more force; but when this is followed by the direction to make the "throat of the air vessel long and narrow to prevent the water in the vessel from being disturbed by the action of the pump," one can only read on in astonished perplexity. Why not cut off the air vessel altogether if it is desired that the action of the pump should not disturb the water in it? That would be the surest way to effect this object. It would be difficult to surpass in point of vagueness and wrongness of principle the calculations anent the opening and holding open of valves given on pages 120 and 121. Firstly, it is said here that the difference of water pressure needed below and above a valve in order to lift it is reduced by the amount of buoyancy possessed by the valve when floating in water. This buoyancy is the weight of displaced water, and it is produced by that part of the difference of pressures above and below which is due to the weight of water between the two levels. Although no pump pressure is required for this, it is still evident that the difference of pressure exists in the water. The weight of the valve, in other words, is not altered by its immersion in water. Again, it is assumed that this difference of water pressure needed to open the valve is maintained after it has opened and the flow through it established; and from this assumption extravagant calculations are made of percentages of pump power spent in holding the valves open. These are wholly misleading. The valves may be, and mostly are, held open by the dynamic action of the water flow—that is, by the extra pressures due to curvature of the streams along the under face of the valve and the vacuum on the upper face due to the flow of the streams past its edges. Neither of these + and − pressures affect in the least the work done in the pump, as they are exerted perpendicularly to the direction of flow at the points where they are developed. The loss in horse-power due to the obstruction offered by valves, &c., is wholly caused by friction against the sides, by viscosity between the partial currents, and by eddy-making.

These are samples of the crudities which disfigure a book which, with their elimination, and with energetic condensation, might be converted into the best English treatise on the subject. The arithmetic would need to be revised throughout, both as to rationality and as to accuracy. For example, on page 268, the "duty" per indicated horse-power of a pump "using 5 lb. coal per horse-power per hour" is found thus:—

$$\frac{5 \times 1,980,000}{112} = 88,214{\cdot}28.$$

Now, as the "5 lb. per horse-power per hour" is an approximate figure, subject to a variation or error of, say, not less than 5 per cent., the final figures 14·28 in this calculation are irrational, absurd, and misleading, as declaring a degree of accuracy which does not really exist in the result. The beauty of this minute calculation is further appreciated when it is observed that with correct arithmetic the result is 88,400, or nearly 200 more than stated, in consequence of mistakes in multiplication. In passing it may be noted that the factor $\frac{1,980,000}{112}$ may be conveniently used in the form $18,000 \times (1 - {\cdot}02 + {\cdot}002)$.

Another example of similarly amusing arithmetic is taken at random from page 270, thus:—

"Total pressure = 78·54in. area of pump
× 500 lb. pressure per square inch
= 39,270 + 50 per cent. for friction,
= 58,905 lb. pressure."

The comparison of the 50 per cent. allowance for friction with the nice adjustment of the calculation of pressure to "5 lb." ought to be amusing even to the writer of this book. Similar entertainment may be had from the statement on page 278 of the horse-power of horses, namely:—

23,412 foot-pounds per min. for 8 hours; or
27,056 „ „ „ „ „ 4½ „ ; or
32,943 „ „ „ „ „ 3 „

These figures are not given as deduced from any special tests, but as standards. The final 12, 56, 43 foot-pounds are delightful. They are standards for all the world over; not for English or French or Russian horses; not for those fed on oats or on any other fodder in greater or less quantity; they are standards for *all* horses.

SHORT NOTICES.

The Factory and Workshop Acts Explained and Simplified. By E. M. Roe, her Majesty's Inspector of Factories. London: Simpkin, Marshall, Hamilton, Kemt and Co. Manchester and Birmingham: Cornish.—Major Roe has written a useful little book with the hope of assisting all to whom the Factory and Workshop Acts apply to find with ease their obligations and privileges. The book first of all explains the "definitions" given in the Acts. Then follow particulars as to the duties of employers, owners, workpeople, and parents; sanitary provisions; the safety of machinery by fencing, and precautions against fire; the periods of employment with meal hours, overtime, and night work, with special exceptions and restrictions; special rules in dangerous trades; arbitration; and references to penalties incurred on infringement of the Acts; together with the powers of various public officers. It has a complete index.

A Directory of the Chief Industries of India, with which is Incorporated a List of Tea Companies and Gardens, Indigo and Coffee Estates, with their Factory Marks, and a Directory of Tea, Coffee, Cinchona, and Cardamon Estates in Ceylon. With two maps. Calcutta: Thacker, Spink, and Co. London: W. Thacker and Co. 1896. Price 6s.—The title to this book sufficiently indicates its nature. The maps show the tea districts and the coal and iron centres respectively, and they are probably as clear as their size will permit.

COLONEL J. T. NORTH.

COLONEL NORTH died on Tuesday suddenly whilst he was presiding at his office in Gracechurch-street over a meeting of a company in which he was concerned, when he was taken ill and died almost immediately of failure of the action of the heart.

Born in the early forties, a solid, sturdy Yorkshireman, shrewd, honest, and quick, with no book-learning or accidental advantages of fortune, patronage, or friends, but with indomitable courage and energy, North was at an early age, whilst yet an apprentice in Messrs. Fowler's workshops at Leeds, selected from his fellows to go out to Peru to superintend the erection and working of certain machinery. He at once set to work to make the most of his knowledge and the best of his time and wits in a strange land, of which to the end of his days he never learned the language. The stories he was wont to tell of his early struggles showed of what stuff he was made. He spied out the nakedness, not of the land, but of the natives, and he set to work to clothe them to his profit. One of his earliest enterprises was the condensing of sea-water for domestic purposes at a place on the coast north of Valparaiso, where rain never falls. Patching up an old iron steamer that had been wrecked on a reef, he converted her into a floating water-tank, and made a good profit by her. Other enterprises succeeded quite as well, notably the working of large guano deposits, and eventually the Leeds apprentice, who had landed in Peru with a salary of £1 a week, went back to England the possessor of great wealth. It is said that just before the war between Chile and Peru he satisfied himself that the Peruvians would be defeated and that they would lose the province of Tarapaca—that singular region on which the beds of nitrate of soda are all that are left to tell of the existence of the great salt fjords and lakes which have been lifted up by volcanic action and desiccated by the sun, never to be melted by any rain, for the whole stretch of coast nearly 300 miles long. Some of these *oficinas* he acquired by purchase, and when the conquering Chilians came to seize upon the lands they found the British flag flying over many square miles of nitrate beds, of which the owner was J. T. North. On his return to this country after an absence of about twenty years, Colonel North—he was honorary colonel of the Tower Hamlets Volunteer Engineers—soon became a familiar figure in the City, built himself a very fine house at Eltham, in Kent, started a racing stable on a large scale, and became a prominent member of all the associations connected with sport. In 1889, the *Times* says, he paid a visit to Chile to strengthen his companies by agreements with the Chilian Government.

Colonel North married a daughter of the late Mr. John Woodhead, a leading Conservative in Leeds—and a representative of that party both in the Corporation and on the Board of Guardians. He leaves one daughter and two sons.

HORSELESS CARRIAGE NOTE.

IT has just been pointed out by a correspondent, writing to a Glasgow daily paper, that the Locomotives on Highways Bill which has now passed the second reading in the House of Lords to legalise the running of horseless carriages, while satisfactory in every way as concerning its provisions for England, is far otherwise in regard to Scotland and Ireland. To many it will come as a surprise to be told that these countries are being treated differently from England in this highly important connection, and the question will naturally arise why one set of uniform regulations should not be made to apply to the whole of the United Kingdom. So far as England is concerned the Bill provides that vehicles propelled by mechanical power, under two tons weight unladen, not drawing any other vehicle, and so constructed that no smoke or visible vapour is emitted, shall be treated as if they were carriages drawn by horses, and shall be subject only to the general regulations of traffic on highways, while the Local Government Board is given power to subsequently make such regulations as it may see fit with respect to the use of horseless carriages. This virtually gives to manufacturers and users in England an entirely free hand in the meantime, while any regulations which may subsequently be made by the Local Government Board will apply to the whole of England equally. As regards Scotland and Ireland, under Clause *C* of the Bill it is enacted that so much of Section 6 of the "Locomotives Amendment (Scotland) Act, 1878," and Section 6 of the "Public Health (Ireland) Amendment Act, 1879," as gives power to regulate the use of locomotives shall apply to horseless carriages. The sections referred to give power to the road authorities in Scotland, and to the urban sanitary authorities in Ireland, to make bye-laws regulating the use of locomotives to sixteen hours out of the twenty-four on such highways as they may fix, situated within their respective areas, and to make general bye-laws for regulating the use of locomotives upon any highway. It is significant as a foreshadow of what may be the result of this mixed legislation to be reminded that in Scotland it was under this Section 6 that the only conviction for running these carriages was obtained. The result of the passing of this measure in its present form will be that so far as Scotland and Ireland are concerned the law will stand exactly as it did before, since every petty local authority will still have power to pass such bye-laws as they may see fit for the regulation of horseless carriages, and restriction of the hours during which they may be run. When it is remembered that these vehicles are capable of covering 200 miles in a day, it can readily be estimated that they may pass through the territory of many local authorities in that time, each having, perhaps, a different set of bye-laws. This cannot but lead to endless confusion and trouble, and tend seriously to hinder in Scotland and Ireland the introduction of this new form of locomotion with its promised advantages.

THE IMPERIAL INSTITUTE EXHIBITION OF HORSELESS CARRIAGES.

THE largest number of motor carriages yet brought together in this country was exhibited at the Imperial Institute on Friday last, when a preliminary inauguration of the exhibition organised by the Motor Car Club took place, the occasion being a private view largely attended by members of the House of Lords and others interested in the Light Locomotives Bill introduced into the Upper House by Lord Harris.

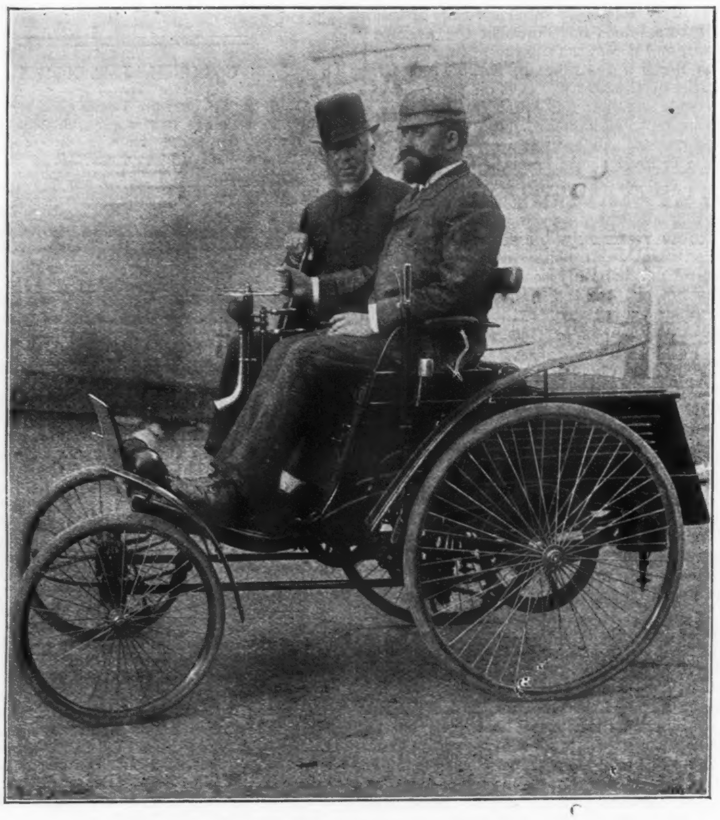

Fig. 1—ARNOLD'S MOTOR CARRIAGE, WITH BENZ MOTOR

In the evening a banquet was given in celebration of the event, and this was most influentially attended, and was made the more interesting by a subsequent display in the Imperial Institute grounds of the travelling and manœuvring powers of a number of the motor carriages and cycles forming part of the exhibition, the grounds being very prettily illuminated for the purpose.

Amongst those present were the Duke of Abercorn, the Marquess of Breadalbane, the Earl of Clanwilliam, Earl of Clarendon, Earl Denbigh, Earl of Dunmore, Earl Galloway, Earl of Kintore, Earl Poulett, Earl of Romney, Earl Waldegrave, Viscount Galway, Earl Russell, Viscount Knutsford, and Lords Ampthill, Derwent, Abinger, Digby, Exmouth, Harris, Fingall, Hillingdon, Howard de Walden, Hyde, North, Roberts, Thring, and Llandaff, most of whom were accompanied by their ladies.

Ample evidence was afforded in proof of the widespread interest now felt in the construction and use of horseless carriages for various purposes, and considerable surprise was displayed at the speed and complete control which the vehicles as now made place at the disposal of the users, and at the satisfactory signs of development towards thoroughly practical vehicles for various purposes. Several of those shown in operation have been briefly described and illustrated in our pages[1], but several new forms were present. The three kinds of motors, namely, steam, benzoline oil motor, and electrical motor, were represented. Vehicles by MM. Panhard and Levassor, by MM. Peugeot Frères, by Mr. Lutzmann, by Messrs. Arnold and Sons, of East Peckham, Tonbridge, Kent, by the Daimler Motor Company, London, by MM. De Dion and Bouton, and by M. Bollée were shown, all of which were operated by benzoline motors. An electric carriage of the Universal Electric Carriage Company, seating four persons, and operated by secondary batteries and a Serpollet steam carriage, were also shown in motion.

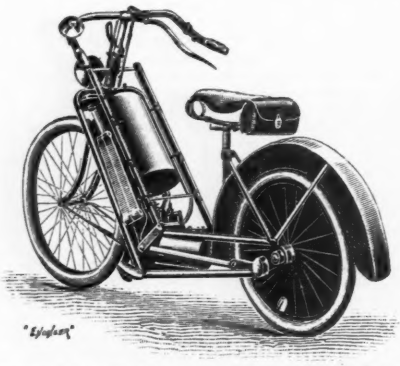

Fig. 6—THE DUNCAN AND SUPERBIE MOTOR BICYCLE

One of the Arnold carriages is illustrated by the accompanying engraving—Fig. 1—and by the sketch plan of the arrangement of its machinery—Fig. 2. These are vehicles for carrying two persons, and they are fitted with benzoline motors made by the Benz Company, of Mannheim. These motors are horizontal, and the ignition is effected by electrical means. Power is taken from the motion shaft by means of leather belts driving a second motion shaft, the belts running on pulleys of different sizes for two different speeds. The second motion shaft communicates motion to the driving wheels by means of a driving chain. The general arrangement is clearly shown by Fig. 2, which does not, however, show the position of the jacket water cooling tanks on either side of the inside of the rear of the vehicle, or of the oil supply reservoir, which carries enough benzoline for about seventy miles run on good roads. One of the vehicles of this build, called a Motor Sociable, to carry two persons, is fitted with a motor of about 1½-horse power, and with cycle wheels having india-rubber tires and ball bearings. Its weight is said to be under 6 cwt., and its price £130. A much larger vehicle by this maker, known as a Motor Victoria, fitted with a large leather hood and with a motor of 3-horse power, costs £230, and is a nice looking vehicle. Several carriages of this make competed in the Paris Bordeaux trial last year, under the name M. Roger, the Paris agent for the Benz manufactures. The steering wheels are carried upon a cross axle with short pivoted ends of the Ackermann type, the main part of the axle having a fore-and-aft pivot, so that the axle is free to accommodate itself to the differential rise and fall of the four wheels. The vehicle illustrated was shown in operation by Mr. Hewetson.

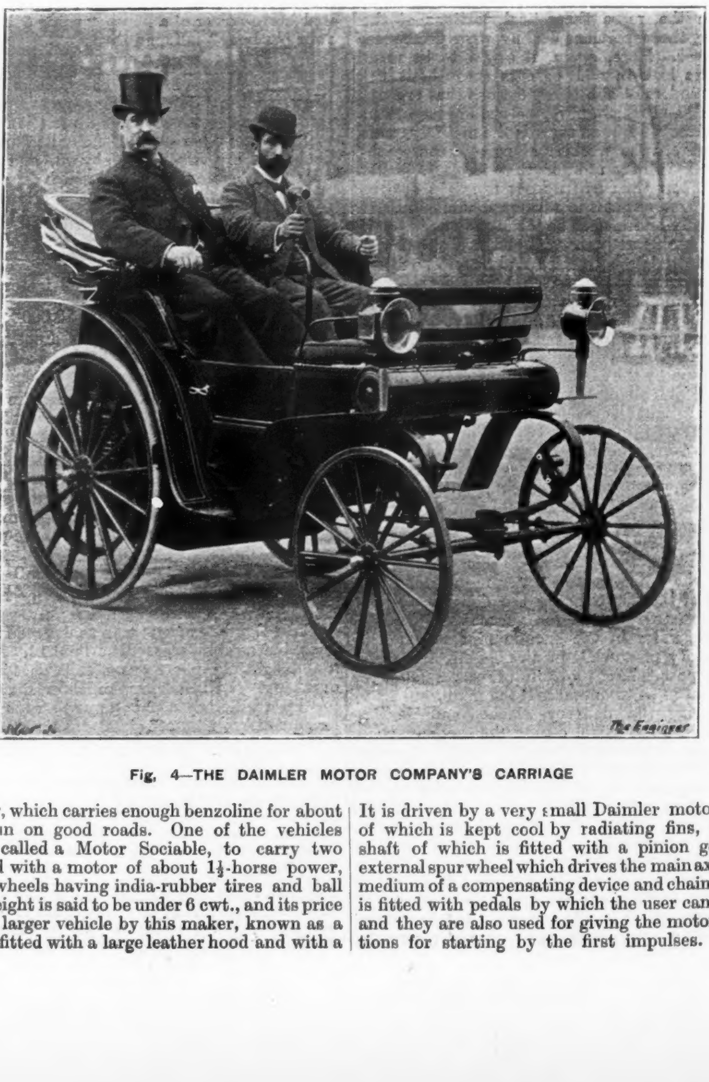

Fig. 4—THE DAIMLER MOTOR COMPANY'S CARRIAGE

The Lutzmann carriage is a high-mounted vehicle of the Victoria type, driven by a horizontal benzoline motor; it was shown in operation, moving in a stately slow-speed manner, by Mr. Koosen, of Southsea. The carriages built by MM. Panhard and Levassor and Peugeot Frères were illustrated by us, as above mentioned; and that owned by the Hon, Mr. Eveline Ellis is shown by the accompanying engraving—Fig. 3. It is propelled by a Daimler motor, operating a fore-and-aft shaft, which by bevel and compensating gear drives the second-motion shaft, provided with spur gear for three different speeds, the motion being communicated to the driving wheels by chain gear. This vehicle is exhibited by the Daimler Motor Company, and was shown in operation by Mr. Ellis.

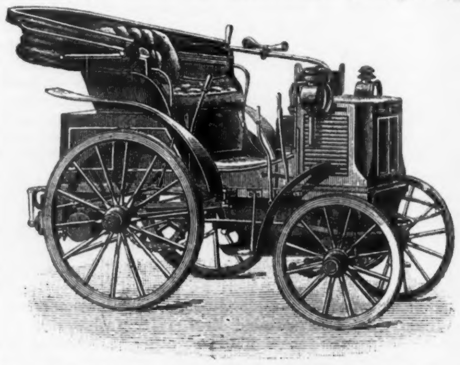

Fig. 3 — PANHARD AND LEVASSOR MOTOR CARRIAGE — DAIMLER MOTOR

Another type of vehicle, namely, the most recent form of Daimler motor carriage, is shown by the engraving —Fig. 4—above, and was illustrated in plan and section in THE ENGINEER of December 20th last.

The illustrations show the arrangement of the vehicle for four persons, with a vertical Daimler motor driving a second-motion shaft by means of belts and pulleys, the belts being tightened or loosened by means of jockey pulleys. The second-motion shaft is fitted with pinions which gear into spur gear rings attached to the road wheel spokes. This vehicle was shown in motion by Mr. Simms, and like that of Mr. Ellis, it attracted attention because of the ease with which it ran and mounted the ramp erected in the grounds, and the facility with which it was steered amongst other vehicles, and round various objects, in a somewhat confined space of the grounds at disposal.

The tricycle shown by Fig. 5, shown in use by the Comte De Dion, is that made by MM. De Dion et Bouton. It is driven by a very small Daimler motor, the cylinder of which is kept cool by radiating fins, and the crank shaft of which is fitted with a pinion gearing into an external spur wheel which drives the main axle, through the medium of a compensating device and chain. This tricycle is fitted with pedals by which the user can assist up hill, and they are also used for giving the motor a few revolutions for starting by the first impulses. This vehicle worked extremely well, and an oil motor bicycle was also shown in operation.

---

[1] See THE ENGINEER, July 20th and 27th, 1894, June 21st, 1895, July 12th, 1895, January 3rd 1896.

The bicycle by MM. Duncan et Superbie is shown by Fig. 6, and is a very nicely finished machine. It is worked by a pair of benzoline motor cylinders, the return stroke of the pistons in which is effected by powerful india-rubber bands stretched on the outgoing stroke. To this vehicle as well as others we have mentioned we must refer in more detail in another impression.

The most remarkable of the smaller vehicles was the tricycle of M. Bollée, previously well known in connection with the steam carriages he has made. This is a tandem tricycle with a low seat between the two wheels in front for the passenger, and a seat to the rear for the operator, who sits nearly over the rear single driving wheel. A small horizontal benzoline motor, designed we believe by M. Bollée, is on one side of the tricycle frame, and drives the rear wheel by means of an endless cotton and rubber belt running over a pulley about 20in. in diameter. Attached to the rear wheel, the latter is so mounted that by a lever in the operator's left hand it can be pushed forward or pulled rearwards, thus slackening or tightening the driving belt. The driving pulley on the rear wheel also acts as the brake pulley, and when the hand lever is pushed forward and the strap loosened the pulley is simultaneously brought into contact with the brake block with more or less pressure as required, the driving-wheel is thus at the same time deprived of driving power and stopped by the brake.

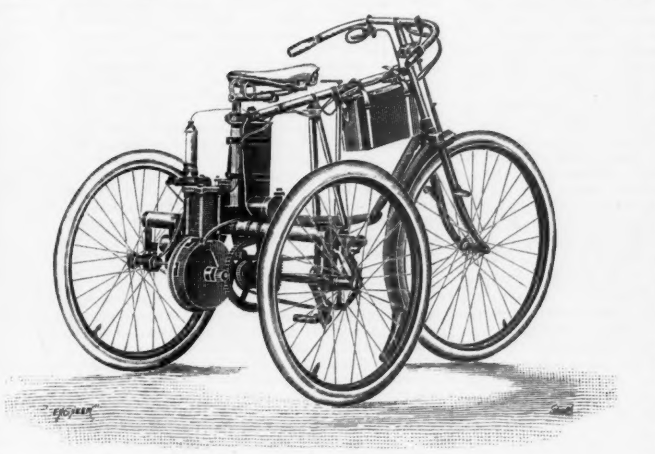

Fig. 5—THE DION AND BOUTON MOTOR TRICYCLE

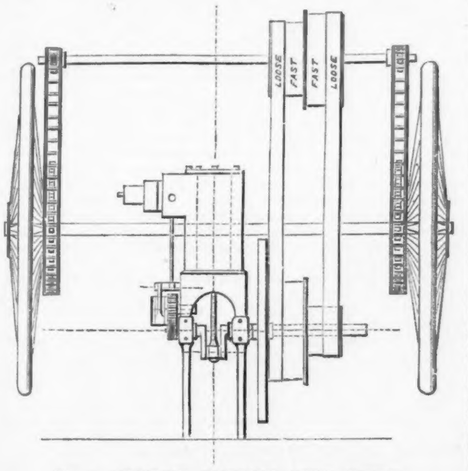

Fig. 2—ARNOLD'S CARRIAGE-BENZ MOTOR

At present we are unable to illustrate or give many particulars of this tricycle, but the very high speed it attained, not only on the straight but round sharp curves, and when dodging at this speed amongst other vehicles, drew the attention of everyone present to it as not only being remarkable in itself, but as having a very daring and skilled rider. It is only about four months since Monsieur Bollée commenced making this tricycle, yet he has already orders for fifty or sixty of them. For the present the one exhibited has been taken to Coventry with a view to its manufacture here, the rights having been bought by the Daimler Motor Company.

To the electric carriage shown in operation by Mr. W. C. Bersey, of the Universal Electric Carriage Company, we must refer in another impression when we have illustrations.

The Serpollet carriage was not of recent construction, and although of interest, does not represent the Serpollet carriage as illustrated by us last year. It is a powerful, but heavy, vehicle as compared with anything that would be looked for as a carriage. Indeed, the steam carriage, though there is little doubt that it will in the future play a most important part among horseless vehicles, cannot be yet said to be at all represented at Kensington. At present the oil or benzoline motor holds the field, and no doubt some of the objections at present urged against it as causing considerable vibration, particularly when the carriage is standing, and as being less easily variable in its speed or power than is desirable, and as having to be kept running when the vehicle is standing, will in some measure be removed; but to the satisfactory steam engine none of these objections apply, and when English engineers, seeing that light horseless carriages are really in demand, give their attention to the subject, there is little doubt that we shall see steam in this, as in every other requirement for motive power, playing a most prominent part.

THE CARDIFF EXHIBITION.

On Saturday this was formally opened by the Mayor of Cardiff—Lord Windsor—and is unquestionably one of the greatest successes of the principality. The attractions are of the most varied character, from a reproduction of old Cardiff to a model of Shakspere's house at Stratford, and from switchback and cycle-race courses to a large gathering of works of art.

For the mechanical and engineering world there is a great deal deserving of very close attention, and it is anticipated that large excursions of practical minds will journey to the Welsh gathering from all parts of South and North Wales, and from the opposite coasts of Somersetshire, Devonshire, and Gloucestershire, since a collection of models of interest to the electric, maritime, and engineering industries of the country has not, in Wales certainly, ever been brought together.

The machinery section is one of the most interesting in the Exhibition. There are over 200 exhibitors, and much of the success of this part is due to Mr. Riches. The electric light plant is in the centre of the building, and comprises four pairs of compound engines, a pair of vertical engines, a large horizontal main engine, and two pairs of smaller engines for the standbys, and supplemental work. These not only form an interesting exhibit, but do the electric work of the Exhibition. Then there are dynamos and exciters in close proximity. There is a countershaft between the dynamos and engines. The machinery supplies the power for the 200 arc and 600 incandescent lights. The engines are supplied with steam from two batteries and two boilers, each of Babcock and Wilcox's multitubular type—1000-horse power, if required. In addition to these four boilers there is a small battery of boilers erected by Messrs. Hornsby, of Grantham, of a somewhat similar type. The steam pipes, after serving the electrical plant, supply a pair of Braithwaite's high-speed engines about 400 revolutions per minute, and calculated to give off 200-horse power. The steam is then carried into the running section, and to the model coal mine, which will be noticed again, with other features of the Exhibition, which is to continue until October.

Another of the most prominent features of the Cardiff Exhibition is the maritime section. The leading shipbuilders, shipowners, and dock contractors of the country have sent exhibits, and as 8400 square feet are allowed, it follows that the display is both large and unique. Sir Wm. Armstrong, Mitchell, and Co., have sent models of steamers, battleships, ironclads, steam launches, and gun carriages. The American Transatlantic Line is represented by a model of the steamship St. Paul; the Barry Dock and Railway Co. by a model of its dock and harbour; Bucknall Bros., of London, by models of their steamers, with a track chart; the Clyde Navigation Co., of Glasgow, exhibits large models of submarine excavators, dock works, ferry boats, swing bridges, and a collection of photographs; Donald Currie and Co. are represented by models of the Dunottar Castle and Arundel Castle, and photographs of African scenery; the Darlington Forge Co. by models of marine engines; Doxford and Son, of Sunderland, by models showing the midship section of a turret vessel, specimens of ship plates, models of cruisers, torpedo boats, and destroyers; Mr. John Dure, of Barry Dock, has a model of hydraulic dock apparatus; the Eltringham Co., of South Shields, exhibit photographs of marine boilers; the Fairfield Shipbuilding Co., Govan, Glasgow, exhibits a collection of models of a number of fine steamers; Kemp, of Whitstable, shows a model of a racing cutter; and a very effective model is that of Southampton Docks and harbour by the London and South-Western Co., also of the company's steamers, Columbia, and Alma.

The Great Western Railway is credited with having sent the largest and finest collection of exhibits ever sent to any exhibition in the country. First, as announced last week, there is the well-known engine the Lord of the Isles. This ended its career when the broad gauge system was abolished, but has been to several notable exhibitions, principally Chicago, where it excited a good deal of interest.

Then there is the middle portion of the New South Wales corridor sleeping carriage, now in course of construction for South Wales. Next samples of rolling stock, sections of different rails on permanent ways, steel stampings; a model of a locomotive with a glass boiler, showing all internal arrangements, and another section exhibiting the complete working of the automatic continuous brake.

The Great Western Railway exhibits include a portrait of Sir Daniel Gooch, whose apprenticeship was passed at Tredegar, a section of the Severn Tunnel, an ingenious machine, and a model of the Emperor. The last contribution lent by Mr. Robinson. The London and North-Western, by its chief mechanical engineer, exhibits a working model of the compound locomotive Dreadnought, which is adroitly acted by a penny in the slot—the money thus collected going to the Railway Servants' Orphan Fund. In addition there is a set of photographs of the various classes of engines used on the North-Western, and a representative selection of rolling stock. The North-Eastern Railway Company, by its chief mechanical engineer, is represented by the present express of the company, Mr. Worsdell's own engine. Then there are two or three models of the Great Northern 8ft. express passenger engine. The Taff Vale Railway, as may be assumed from the fact that Mr. Riches, locomotive superintendent, is one of the most active members of the committee, is well and variously represented, rolling stock figuring largely, and the ingenious machine Mr. Riches designed for reaching the entombed miners at Tynewydd. There is also an instrument for recording the speed of trains. The London and South-Western Railway Company is represented by a pair of coaches from the Wadebridge and Bodmin Railway; the Lancashire and Yorkshire by models of the rolling stock of 1825, and that of the present day. The Great Eastern, Great Northern, and Caledonian Railways are also represented by railway exhibits, &c., the Great Eastern by a model of the oil-burning engines introduced by Mr. Holden.

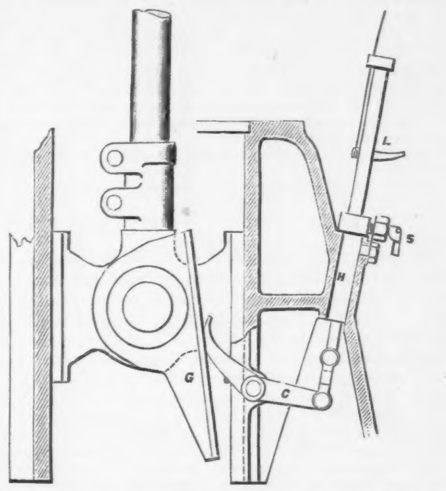
The London and India Dock Committee exhibit a plan of the Victoria and Albert Dock, with models of vessels, wool warehouses, East India Docks, tipping lift, &c. Lloyd's Registry of British and Foreign Shipping is exceedingly well represented by thirty models from the primitive wooden vessels of old days up to the latest ocean steamers. The Mersey Dock and Harbour Board is represented by models of landing pontoons, vessels, &c. Morel Bros., Cardiff, exhibit models of the steamers Llandaff and Penarth; models of marine engines, evaporators, &c., are shown by the North-Eastern Marine Engineering Co., Wallsend; and Messrs. Siemens Bros. and Co., of London, have on view a fine model of the Faraday, which is specially used in laying telegraph cables.

We purpose doing fuller justice to the vast accumulation of exhibits later on, and single out occasionally for special note those of marked interest.

Too much credit cannot be given to the executive for their successful labours in bringing such an attractive exhibition to the notice of Wales, and that, too, in combination with such an ever-increasing flow of amusement and innocent pleasure as will maintain public interest to the full for the next four or five months.

INDICATOR GEAR FOR HIGH-SPEED ENGINES.

For engines running at a high speed it is essential, if trustworthy diagrams are to be obtained, that the connection between reducing gear and indicators should be as direct and short as possible. We have pleasure in publishing an illustration and description of a new indicator gear which is being applied by Messrs. Davey, Paxman, and Co. to the Peache high-speed engine. It will be seen that the reducing motion is obtained by fixing an inclined guide on the engine crosshead and providing a double-ended lever working on a fixed pivot. One end of this lever is made circular in profile, and is kept in contact with the inclined guide; the other end is connected by link to a plunger working in a tube, the tube being fixed in a suitable position. At the upper end of the tube a spiral spring is attached, and exerts a constant upward pull on the plunger so as to keep the lever in contact with the inclined guiding surface. Through the upper part of the plunger is fixed a cross-piece, one end of which carries the indicator cord, and the other end is formed as a thumb-piece. In practice it is intended that the gear shall only be in action when required, and for the purpose of throwing it out of action a spring catch is provided. If by means of the thumb-piece the plunger is pressed down until the spring catch drops into a recess in the plunger, the lever is then held completely out of contact with the inclined guide, and remains so until the gear is again required, when by releasing the spring catch it is at once thrown into action again. In the engraving *g* is the inclined guide, C the lever, *p* the plunger, L the cross-piece, *s* the spring catch.



TRACTION ENGINES ON ROADS.

The Select Committee of the House of Commons, which is appointed to investigate the laws relating to the above, sat again on Thursday, the 30th ult., and were engaged in taking evidence from witnesses from Scotland. The Lord Provost of Aberdeen—Mr. Daniel Mearns—was the first to be called, and in the course of his examination said that this city had 110 miles of streets and roads paved with granite setts, an acreage of 6694, and a population of 135,000. He computed the cost of repairing the damage done to roads by traction engine traffic to the Corporation at £1000 per annum. This was chiefly due to the cross bars on the tires. He thought that local authorities should retain the power to make their own bye-laws, impose licence duties, license drivers, and inspect engines before granting licences. The witness saw no objection to the statutory limit of speed being increased to three miles per hour in towns and villages, and suggested that the weights hauled should be limited as follows:—For seven-ton engines, two trucks weighing six tons loaded; and ten-ton engines, three such trucks.

Mr. William Dyack, surveyor to the city of Aberdeen, attributed the whole of the damage done to the surfaces of the roads by traction engines to the cross-barred wheels, and suggested that the local authorities should have the power to authorise the use of any approved form of wheel. Statutory loads, in the opinion of witness, should be governed by the power of engine, but the length of trains hauled should be limited to three trucks, while both drivers and engines should be licensed, the latter after being inspected. Mr. Dyack saw no objection to the statutory limit of speed being increased to three or four miles an hour in towns.

The Aberdeen County Council was represented by Mr.

J. O. MacQueen, who is also chairman of the Aberdeen District Committee, a body having charge of 280 miles of roads. This witness informed the Committee that, owing to the large increase in traction engine traffic, the expenditure on the upkeep of the roads had risen from £3500 three years ago to £5400 per annum, while in the county the cost of maintaining the roads in 1892 was £21,900; and in 1895, £23,900. There were over sixty engines in use in this district weighing up to fourteen tons. Speaking of the "extraordinary traffic" clause, he considers this unworkable as at present constructed, and suggested the registration and licensing of engines by local authorities on the following scale:—Engines under six tons, 1s. per annum; over six and under seven tons, £7; over seven and under eight tons, £8; over eight and under nine tons, £9; and over nine and under ten tons, £10; with an increase of £2 per ton for engines above this weight.

Mr. Wight, manager of the Association of Traction Engine Owners of Aberdeenshire, Banffshire, Kincardineshire, and Morayshire, explained that the cross bars of the driving wheels of engines only did damage to the granite setts when these were laid upon a concrete foundation, and he considered this was due to a want of elasticity in the bed of the road. He said his association had no objection to a universal licence duty of £15 per engine, and would not object to the restriction of hours for travelling so long as the hours were universal. He thought that agricultural engines should also be licensed, and suggested a fee of half that mentioned above.

The Committee met again on Monday last and heard evidence from Sir Arthur Grant, a landowner in Aberdeenshire, who employs traction engines chiefly for hauling goods and thrashing machinery. He said that there were 230 engines and 328 wagons employed in Aberdeenshire, and the capital involved was between £130,000 and £135,000. The reason for this large amount of road haulage was the want of railway accommodation. The witness saw no objection to the payment of a universal licence fee of £25 upon engines engaged exclusively in haulage work, but considers a £10 fee sufficient for those which are engaged partly in agricultural work. He thought that the engines should be limited in weight to ten tons, and that the statutory limit of speed outside of towns and villages might be raised to six miles per hour.

Mr. W. Smith, Chairman of the Road Committee of the County of Forfarshire, gave particulars of the bye-laws made in his district for recovering from owners for damages done to the roads by their engines, and stated that instead of imposing a licence duty or a tonnage rate they would prefer to have the power of recovery from engine owners for all such damage as could be proved. Mr. Dunlop, magistrate for the City of Edinburgh, and member of the Corporation, was the last witness taken. He said they had found no damage done to their paved streets by traction engine traffic, which was restricted to the hours between 6 p.m. and 10 a.m. He would not recommend the giving-up of the powers to make bye-laws to a central authority.

The Committee again adjourned till yesterday—Thursday.

THE ROYAL SOCIETY CONVERSAZIONE.

AT the Royal Society conversazione, on Wednesday, there were, as usual, displayed various novelties that have lately enriched the domain of experimental or practical science, and, as might be expected, Röntgen's discovery was duly to the front, and at the exhibits of Mr. A. A. C. Swinton and of Mr. Herbert Jackson, the now usual exposure of the arrangement and shape of one's hand bones, of the contents of a closed wooden box of drawing instruments, and of one's own and other people's purses, and of the transparency of the diamond, aluminium, &c., and of the opacity of glass, &c., could be investigated with undiminished enthusiasm under a gratification according to temperament. Whilst Mr. Sydney Rowland exhibited a series of prints illustrating the application of this principle in surgery that were very striking, a further exposition of these rays was shown by Professor Sylvanus Thomson. An upper aluminium plate was electrotyped by them and transmitted the effect to a sheet of lead below with a pattern cut out and covered with aluminium; the corners of the lead plate were bent down, and supported it over a sheet of glass, and by means of electrical dust the portions electrified were rendered evident; and as the glass became electrified where the aluminium window permitted transmission, the shape of that window was reproduced on the glass, and so were the marks of the supporting corners of the lead plate where they were in contact with the glass. Ordinary photography was represented by printing machines and photographs of spectra, &c.; whilst colour photography had two exponents, Professor Meldola with Lippmann's interferential method, and Mr. F. E. Ives with his stereoscopic photo-chromoscope, in which the excellence of the pictures and the simplicity of the apparatus are most striking. Photography leads us to the exhibit of Professor Hartley, F.R.S., which consisted of an impressive series of photographed spectra illustrating investigations of the Bessemer flame, as seen at the North-Eastern Steel Company's works at Middlesbrough-on-Tees, in which the presence of the rare element gallium was recognised by a single line in its spectrum, and separated from both the metal and the ore of the district. One of the most striking photographs consisted of thirteen superimposed spectra taken at intervals during the "blow" and also during the "over-blow." The spectra slightly overlapped the series, showed the increase of temperature during the combustion of the carbon and the persistency of the gallium, which could be detected in ten of the spectra; that is in the spectra of the blow, but not in those of the over-blow. Another exhibit owing its existence to photography, by Professor Worthington, F.R.S., and Mr. R. S. Cole, showing instantaneous photographs of splashes, was of much interest. The photographs had been taken each with an electric spark giving an exposure of less than three-millionths of a second, which could be so timed as to pick out any desired stage of the splash within limits of error not exceeding about two-thousandths of a second. In this way the progress of a great variety of splashes, light liquids in light liquids, heavy liquids in heavy liquids, solids in liquids, &c., had been followed, and the various stages recorded were to be seen. It was remarkable how the character of the material altered the movements incident to the splash, resulting in the formation of little basins, the sides of which became distributed in spray or driplets, or the rising up of a column that toppled over at the top and dispersed, or the formation of a bubble, and others.

Professor Ewing, F.R.S., showed a new apparatus for measuring the magnetic permeability of iron or steel. The samples are used in the form of short rods, and a rod to be tested is compared with a standard rod, the magnetic qualities of which have been determined beforehand. The two rods lie parallel with magnetising coils wound on both their ends, being joined by two short yokes, so that the whole forms a single magnetic circuit. When the induction in both rods is the same, the yokes are at the same magnetic potential, and in that case a magnetic detector placed between them is not deflected; therefore, in making a test, the number of turns in the magnetising coil of the rod to be tested is varied until this is the case, and the magnetising forces required to produce the same induction in both rods is ascertained. The magnetic detector which shows when two rods have the same induction consists of a compass needle placed in a gap in an iron bar joining the two yokes. Taking into consideration its similarity to the Wheatstone bridge, the author proposes to call the instrument a permeability bridge. It can be worked with great ease. The by no means least fascinating exhibits were modifications of an experiment of M. Charles Margot by Professor Roberts-Austen, C.B., F.R.S. A wire of aluminium suspended horizontally between inductors was raised 400 degrees above its melting point by a current of 30 ampères, but a film of oxide on its surface prevented the wire from breaking. It thus formed an electrified liquid cylinder, and by means of a magnet could be contorted into all sorts of curves, and could be made to tie itself into a knot, ultimately breaking on account of local thickening. In another arrangement the aluminium wire was held vertically, and the lower attachment was made to revolve. The contortions of the bright hot cylinder of molten aluminium reminded the observer of the struggles of a worm on a fish-hook. Messrs. Read, Campbell and Co. showed a device for aërating water in a bottle. It consists of a pear-shaped receptacle about 1⅛in. long, ⅝in. diameter at the thickest part, punched out of sheet steel; it is charged with compressed gas, and the little orifice is either closed with an air-shrunk plug at the narrow end, round which the steel is compressed, or by compressing the steel itself, for which a special stopper is supplied. The "drop," as the pear-shaped receptacle is called, is placed narrow end up in the cap of the stopper, which is hinged. The cap is turned over and the arrangement for clamping it brought over the top; on this is attached a cam, which at the top of the stopper works on a button, to which is attached a steel needle; this is forced into the base of the "drop," punctures it, and the gas escapes and aërates the water in the bottle. They seem to be very safe; when heated to a high temperature the ebonite plug gives and the gas escapes without great force, as the drop burst with but little violence, and if crushed, the same harmless behaviour characterises these little bombs, at least, according to Professor C. V. Boys, who himself exhibits geometric wall brackets and geometric steady blocks, the rigidity and stability of which are obtained by having a skilful arrangement of V grooves, indentations, and angled corners, so that the brackets not alone make firm supports for physical apparatus, but the latter can always be maintained in a definite position, and when removed for use can be replaced in the same position, whilst the supports can be piled up to any height, but being geometrically clamped, carry physical apparatus with perfect steadiness.

Retaining its gases, Professor Clowes has applied his hydrogen testing flame and cylinder to a portable apparatus supported in a tripod, the idea of Mr. Boverton Redwood, so that gas from electric culverts can be tested. It is a neat portable apparatus, and gives good indications. Then the Gas Cylinder Committee, lately nominated at the request of the Home Office, had an exhibit showing the unsuitable character of hard or unannealed steel for gas cylinders, the pliant and resistant characters of good soft annealed cylinder and the violent destructive character of the explosion of mixed gases under pressure which no practicable cylinder can withstand. Professor Liversidge, F.R.S., showed flat etched surfaces of gold nuggets and ingots, demonstrated the internal structure in all cases crystalline, and gave an insight into the mode of formation of these masses.

Mr. Carl Jeiss exhibited new portable binocular field glasses and stereo telescopes, which by arrangements of prisms and astronomical oculars the rays passing from the object glass to the eye piece undergo four reflections at surfaces of the prisms, and emerge from the last prism with undiminished intensity. By these arrangements much enhanced effects are claimed to be attained. We have not space to dilate on the interesting display of ancient astrolobes and other instruments exhibited by Mr. Lewis Evans, nor to more than mention Mr. Henry Balfour's exhibit showing the composite character of the archers' bows of many nations, notably those of the far East, China, Japan, &c. Beautiful sections show the skilful arrangements of horn, wood, and sinew adopted, which to a certain extent had also been adopted by Germany. Altogether there were exhibits suggesting many matters of interest to supply topics of erudite conversation and friendly discussion during the evening.

THE BRISTOL ASSOCIATION OF ENGINEERS.—At the invitation of Mr. John Price, the contractor for H.M. docks at Portsmouth, the annual excursion of the above Association was made to that place on Thursday, the 30th ult. The party was taken over the dry docks that are being made, and which are the largest of the kind in the world. The docks are of massive construction, and are faced throughout with white Cornish granite. The dams at the entrance are of exceptional size, and although special difficulties arose in connection with them, they have been perfectly overcome. It is expected that one of the docks will be completed in a few months, although something like two years out of the five years allowed for their completion are yet unexpired. The members were permitted to view the works by the kind permission of Major Exham, R.E., whose resident staff did all in their power to make the visit a success. The party was conducted by Mr. Price and his assistants, including Mr. Reeves and Mr. Manton, the agent-in-charge. The details and history of the undertaking were explained by the Admiralty engineer, Mr. Colson. The jetty, in course of construction by Mr. Lovatt, was explained by his representative, Mr. Prowse. By the special permission of Admiral Rice, superintendent of the dockyard, the party was enabled to inspect a man-of-war, torpedo catcher, the chief shops, and the pumping station. The visitors were subsequently sumptuously entertained at lunch by Mr. Price. Mr. Price, in proposing the health of the Bristol Association of Engineers, dwelt on the importance of the development of the Bristol Docks estate. Mr. Ryan, as president of the Association, thanking Mr. Price in reply, alluded to his honourable connection with the Barry Dock and the Manchester Ship Canal. He concluded by proposing the health of Admiral Rice, and of Major Exham and his staff, coupling with the toast the name of Mr. Colson, the engineer-in-charge. Mr. Price's health was proposed by Mr. McCurrich and Mr. Colson, and the proceedings terminated by Mr. Prowse proposing the health of Mr. McCurrich, the engineer of the Bristol Docks.

THE INSTITUTION OF MECHANICAL ENGINEERS.

ADDRESS BY THE PRESIDENT—MR. E. WINDSOR RICHARDS.

IN glancing over the many able addresses of former presidents of this and cognate Institutions, I observe that the opening remarks often refer to the difficulty experienced in finding subjects to discourse upon. I too must commence in the same manner; for I confess I have found it a most difficult task to decide upon themes which could be either interesting or instructive to so learned a body of engineers and metallurgists as that forming the Institution of Mechanical Engineers. Our Institution does not confine its attention solely to the construction of machinery, as our papers and discussions show. We are equally interested, scientifically, practically, and commercially, not only in the designing of every description of installation, but also in the manufacture itself of iron and steel, so that probably I need not use words of apology for departing somewhat from the path generally followed by presidents when addressing the Institution.

Much has been persistently said and written for some time past about the decadence of our metallurgical and engineering industries; it has been alleged that the machinery we employ is neither so economical nor so efficient as that of late years adopted in competing countries; that our commerce has declined for want of energy and enterprise on our part; and that we are being rapidly outstripped in the race for the supremacy which we have so long enjoyed. As all the members are deeply concerned in this matter, and are pre-eminently those who should remove these reproaches if they are found to be merited, I thought I would lay before you some examples of actual practice, for enabling us to judge to what extent the charges made against us can be justified. This subject having been decided upon, it was my intention at the outset to describe the principal features of the machinery and plant in use at home and abroad for the manufacture of iron and steel, from pig iron to the finished products of rails, plates, billets, girders, and wire rods. But it soon became evident that with the limited time at my disposal it would be impossible to do justice even to the first portion, namely, the manufacture of pig iron; so that on this occasion I must confine my observations almost exclusively to blast furnace engineering. The principal object, then, of this address is to direct the attention of metallurgical engineers to blast furnace practice as it stands to-day, with regard to production, efficiency of appliances, and economy of results obtained; and, where possible, to give cost of labour per ton produced; and so to ascertain the relative positions and prospects in this department of engineering metallurgy, at home and in America, Germany, Luxemburg, France, and Belgium.

You are aware that in the summer of last year a delegation, organised through the British Iron Trade Association, visited Belgium and Germany, with the view of ascertaining how it was that those countries were able not only to compete with us in neutral markets, but also to send their products into our own country. The report of the delegation has been printed and published, and gives a large amount of interesting information, showing that the subjects inquired into have received most careful thought and attention. The inquiry must have entailed great labour, much time and consideration, and considerable tact. The members of the delegation are certainly entitled to the best thanks of all interested in engineering and metallurgical industries. The report deals more fully with the details of the cost of the labour of making finished iron and steel than with that of making pig iron; and directs attention to the much lower rates of wages ruling in those countries, more especially in Belgium, than here. The conclusions arrived at are that much more care and attention is given abroad than at home to details of working, that the workmen are far more industrious, and less given to strikes than ours; but the main question we have to consider after all is, what is the total labour cost per ton of material produced, rather than upon how low a rate of wages a continental workman can live, in comparison with the rates ruling here. I am always inclined to believe that, even with the higher rates paid to labour, the cost per ton is not so much more than that of the so-called cheap labour. This view would seem to be confirmed by the statement made by Mr. Herbert, Secretary to the American Navy. He says that the United States can build better warships at a cheaper rate than any other country except Great Britain, which is in that respect but slightly in the front; and he adds that American ships are, however, type for type, equal to the best in the British Navy. Now, as labour forms so large a percentage of the cost of buildin a ship, it would seem that a highly paid workman is more efficient than a cheaply paid one.

Many conflicting statements are made as to the extent to which continental countries can compete with us now, or are likely to compete with us in the near future; and this subject is of such vital importance to us as to call for an exceptional amount of attention at our hands, for we are naturally most desirous not to relinquish any of our trade in neutral markets, and especially are we anxious that material from abroad should not be sent into this country. It is necessary to bear in mind, when accusing ourselves of want of enterprise, that we should make an important and broadly marked distinction between competition which is founded on merits—that is, on the capacity of one country to produce a commodity cheaper than another by virtue of the possession of cheaper or more effective labour, cheaper materials, cheaper transport, or more modern equipment and plant—and competition which is protected by tariffs. In the examples I am about to cite, the information has been gathered by visits to the several countries, and inspection of the various works; but as such descriptions in an address of an hour's duration can only be briefly dealt with, and principal figures only can be given, it would be greatly to the advantage of the Institution if the members would take up the subjects touched upon, and contribute papers giving fuller descriptions, and so by raising discussion bring out results of working which would greatly benefit the industry.

British productions and blast furnaces.—In the years 1881-82-83, which were years of fairly good trade, the production of all descriptions of pig iron, spiegeleisen, and ferro-manganese in Great Britain averaged, in round figures, 8,500,000 tons per annum. In 1893, a year of bad trade everywhere, the production had fallen to 6,829,841 tons. In 1894 the production had increased to 7,364,841 tons, obtained from 323 blast furnaces, giving an average of 22,800 tons per furnace. As these results cannot be considered satisfactory when compared with those of other countries, the following figures show in which district the outputs were lowest. They are given in the order of production; and allowance must be made for those making cold-blast iron, and using coal, and rich or comparatively poor ores.

District.	Tons.	Furnaces.	Average per furnace.
Cleveland	2,963,419	87	34,062
South Wales	708,856	22	32,220
West Cumberland	674,840	20	23,742
Scotland	655,614	50	13,112
Lancashire	598,023	20	29,651
South Staffordshire and Worcestershire	315,924	25	12,637
Lincolnshire	287,384	13	22,106
Nottinghamshire and Leicestershire	226,950	14	16,210
Northamptonshire	212,411	14	15,172
Derbyshire	210,860	20	10,543
South and West Yorkshire	202,255	13	15,558
North Staffordshire	195,869	13	15,062

The total production of pig iron in 1895 was about 7,900,000 tons.

To the Cleveland district more than to any other must be given the credit of having greatly improved blast furnace construction and practice; and it still maintains the leading position in this country in the production of all descriptions of iron and steel.

For many years it was a school which engineers of all countries visited to their benefit. The district is much indebted to such men as Vaughan, Bell, Gjers, and many others. It was here that Cowper's fire-brick stove was brought to a practical success by Cochrane, who put up the pioneer stove to heat the blast for one tuyere only. This stove was filled with regenerative bricks, and heated from below by coal burnt on a grate, allowing the cold gases to escape through a chimney fixed on the top of the stove; it was not long before the bottom bricks proved unequal to the support of the bricks above, and the result was a collapse, but not before decided success had been attained in economy of fuel, due to the increased temperature of blast obtained. Encouraged by this success, a pair of stoves was erected sufficient to heat the blast for one furnace, and was set to work in October, 1860. Contemporaneously with these applications of fire-brick stoves, Whitwell's apparatus for heating the blast was adopted at Consett, and rapidly extended to other districts, as well as to France, Belgium, and Germany, and the United States. The adoption of this system of heating the blast effected a saving of about 2½ cwt. of coke per ton of pig iron above that obtained by cast iron pipe stoves, besides permitting a higher pressure of blast to be used, and thus increasing the output of the furnace; indeed, the invention of fire-brick stoves rendered possible the large productions of to-day.

Last year's work of Messrs. Cochrane's three furnaces, which have been fully described in the "Proceedings" of the Institution, shows highly interesting figures. With ironstone from the Cleveland mines, containing raw an average of 29 per cent. of iron and calcined 41 per cent., they made 123,594 tons of pig iron over the whole of 1895, being an average of 41,198 tons per furnace, or at the rate of 792 tons per furnace per week, with an expenditure of 21·12 cwt. of coke per ton of iron. The average temperature of the blast over the twelve months was 1490 deg. Fah.

A good and fair example of the working of a Cleveland blast furnace using native ironstone over the last twenty years is furnished by No. 8 furnace at Eston, which was put into blast in 1874, and blown out in 1894, having made from one lining 484,412 tons of pig iron. During that period the furnace was damped down thirteen weeks, in consequence of the Durham colliers' strike. The average output per annum was 24,000 tons. Formerly cast iron pipes were used for heating the blast, but latterly Cowper stoves. During the last year of its working it made 26,168·14 tons of good grey iron, using 26,891·18 tons of coke, being an average of 500 tons of iron per week and 20·55 cwt. of coke per ton of pig.

Furnaces erected at Eston in 1877 continue to produce a little under 1000 tons of Bessemer iron per week, using 50 per cent. ores. The best of these furnaces produced last year 50,800 tons of iron with 18·60 cwt. of Durham coke per ton of pig. These furnaces without any arrangements for cooling the boshes last about five years, and give about 250,000 tons of iron, and then require relining. With present engine-power the above quantity cannot be increased; it has therefore been decided to erect six vertical direct-acting high-pressure engines, as there is no water available for condensing; the air cylinders are 84in. diameter and 5ft. stroke. These engines of exceptional strength are being constructed by Messrs. Tannett Walker and Co., Leeds, and are to supply 25,000 cubic feet of air per minute at from 8 lb. to 10 lb. pressure per square inch to each of three blast furnaces. The boilers are of the Lancashire type, 30ft. long and 8ft. diameter, with two flues, 3ft. 3in. diameter, having five cross Galloway tubes, and are to work at 80 lb. pressure: so that greatly improved results in working are expected to follow shortly upon their completion.

At Jarrow-on-Tyne a blast furnace plant was constructed with all recent improvements, from which greatly improved results were expected. As these results were at first realised, it is of value to ascertain the causes, in order to avoid similar failure in future. The furnace No. 5, is 75ft. high bosh 20ft. diameter, having several cooling plates, angle of bosh 80 deg., hearth 11ft. diameter, throat 16ft., bell 11ft., capacity of furnace 14,150 cubic feet, eight gun-metal tuyeres 5½in. diameter, placed 6ft. above the hearth level. Blast of 3¼ lb. pressure per square inch, heated by four Cowper stoves, 73ft. high and 22ft. diameter, to a temperature of from 1400 deg. to 1500 deg. Fah. Durham coke with 8 per cent. ash and 1 per cent. sulphur, 19½ cwt. per ton of Bessemer pig iron. Production 1000 tons per week from Bilbao and African ores averaging 50 per cent. of iron, increased to 1100 tons during the last few weeks. Limestone 8 cwt. per ton of pig. One pair of compound condensing vertical blast engines, high-pressure cylinder 54in. diameter, low-pressure cylinder 72in. diameter, air cylinders 100in. diameter, stroke 5ft., making seventeen revolutions per minute, for 1000 tons of iron per week. From such an installation as this it would be expected that a large production would be readily obtained at a low cost; but the furnace worked with great irregularity, and was continually hanging and slipping. Increased blast pressures were tried, and failed to produce any improved results. The cause was evidently traceable to the steep boshes. So unsatisfactory and costly was the working that the furnace was blown out in June, 1893, and the boshes were altered to 68 deg. Since this alteration the furnace has worked well and economically. The engineering portion of the whole plant is well carried out. For a furnace having such a large reserve of blast and heating power, an output of only 1100 tons per week cannot be considered a good return for the large amount of money expended.

In a paper read and discussed at the Middlesbrough meeting of this Institution in August, 1893, our Past-President, Mr. Jeremiah Head, described a blast furnace of peculiar internal form, designed by Messrs. Howson and Hawdon, of Middlesbrough. On visiting last month the works of Sir Bernhard Samuelson and Co., in order to ascertain what success this new form of furnace had attained, I found there are five now in operation, giving such satisfactory results that a sixth is being prepared. Two of the furnaces were making Cleveland iron, and three hematite. No. 5 furnace, with 18ft. bosh, 70 deg. angle, 11ft. hearth, 84ft. high., had made during the previous ten weeks, with Rubio ore containing 50 per cent. of iron, an average of 1053 tons per week of good grey Bessemer iron with a consumption of 18·1 cwt. of coke per ton of iron, the coke containing 10 per cent. of ash. The blast is supplied by ordinary vertical compound condensing quick-running engines at about 4½ lb. pressure per square inch, and is heated by Cowper stoves to 1400 deg. or 1500 deg. Fah. By increasing the volume and maintaining the heat of the blast, Mr. Hawdon expects shortly to attain 1200 tons per week.

The Dowlais Cardiff new blast furnace plant is remarkable for efficient and economical working. The two furnaces, have 20ft. boshes, 10ft. hearths, are 75ft. high, and from Bilbao ores containing 50 per cent. of iron each furnace produces 1250 tons per week of good grey Bessemer iron, with a little over 19 cwt. of coke per ton. The production can be readily increased, should the state of trade require it.

From the foregoing statements and descriptions, which can be compared later with the figures obtained in other countries, it will be seen that present British practice with ores containing 50 per cent. of iron averages 1000 tons of pig per week, with a strong tendency to increase. The coke consumption varies from 18½ to 20 cwt. per ton of pig. Labour cost, including everything in connection with the blast furnaces, from unloading the ores to loading up the pig iron, but excluding establishment charges, is as low in one instance as 24d. per ton of pig, rising to 30d. for hematite iron, and to 36d. for Cleveland iron. Having described a sufficient number of works to give a fairly adequate idea of the state of blast furnace practice at home, I now pass on to the consideration of the American pig iron industry.

American blast furnaces.—Taking the same periods as before, namely, the three years 1881-82-83, we find the average production of all descriptions of pig iron for each of these years was 4,500,000 tons; and it has since increased by leaps and bounds, till in 1895 the enormous production was reached of 9,446,308 gross tons; the previous year being one of bad trade, the output was 6,657,388 gross tons. In the month of March of the present year 1896 there were 203 furnaces in operation, giving an average output of 48,000 tons per furnace per annum; so that it is probable the total production of the present year will reach ten million tons. The average production is not of much value, as in the above number there are twenty charcoal furnaces in operation. American blast furnace practice is by far the most interesting and instructive of all; it is receiving the most careful study of continental engineers, and merits our best consideration.

At South Chicago and at many other works there are furnaces doing really marvellous work. A type of furnace which has worked most satisfactorily and economically at the Edgar Thomson Works is 90ft. high, 20ft. bosh, having an angle of 75 deg., throat 16ft. diameter, crucible 13ft. diameter, eight tuyeres placed 8ft. 6in. above the level of the hearth, projecting 6in. inside the lining, and having nozzles 8in. diameter; Cowper fire-brick stoves heating the blast to about 1200 deg. Fah. Each furnace is blown by two single vertical blast engines, having steam cylinders 40in. diameter, and air cylinders 84in. diameter, together supplying about 26,000 cubic feet of air per minute at 10 lb. pressure. This furnace produces the extraordinary quantity of 11,000 tons of Bessemer pig iron per month, when using Lake ores containing 62 per cent. of iron. On many days of 24 hours the output exceeds 400 tons, using the very small quantity of 1790 lb. of Connellsville coke to 2240 lb. of iron, the coke containing 11 to 12 per cent. of ash.

The desirability and economy of these large productions of iron are questioned by many engineers and managers, owing to the hitherto great wear and tear and speedy destruction of the brickwork forming the lining of the furnace. But these objections have latterly been to a great extent surmounted, and are now best answered by the results obtained from furnace I at the Edgar Thomson Works. This furnace has been in blast for more than five years, and has made over 650,000 tons of iron, with an average coke consumption, including all stoppages through strikes and other causes, of 1889 lb. per 2240 lb. of iron. Special means of preserving the bosh lines of the furnaces are adopted, and are highly effective; indeed, the success attained is due in a great measure to this plan, which greatly prolongs the life of the furnace. Cooling plates or flat water-boxes are placed in rows about 2ft. apart, from the top of the tuyeres up to the height of the top of the boshes; they are made of gun-metal, about 5ft. long, shaped to the curves of the furnace, and placed about 6in. away from the inside line of the bosh; they are about 4in. wide by 3in. thick, and have water running continuously through. The two rows above the tuyeres, and the second and third above these, are connected together to save water; and above them three rows of plates are connected together. Before being put into position the cooling plates are tested by hydraulic pressure. Should a plate leak at any time during working, it can be readily withdrawn and another substituted. The crucible below the tuyeres is kept cool by a strong cast iron plate surrounding the furnace; a coil of 1¼in. pipe is cast therein, which serves for the circulation of water.

Another bold change has been made in the size of the bricks used in the construction of the furnace. Formerly, and as is the practice now in other countries, a huge lump of clay was used, sometimes as large as 30in. long, 15in. wide, and 6in. thick. Such a mass it was almost impossible to bake thoroughly to the core. Of late years we have reduced this thickness to 3in. with improved results; but the sizes now used in America have been reduced to 13½in. long by 3in. thick, and 9in. by 3in. to break joints, the whole 3ft. thickness of the furnace walls being made up of two 13½in. and one 9in. brick.

In order to obtain a large output with economical results, American practice adopts a large hearth, and a comparatively small diameter of bosh; the latter gives as much iron as the larger bosh, and uses less fuel per ton of iron by reason of the gases being distributed equally and rapidly over all the ore, and not working in channels as with a larger bosh. The quantity of iron produced depends on the power of the furnace to burn fuel, and in order to do this a large hearth is necessary, together with a large volume of high-pressure blast; when these are provided, the narrower the bosh the more oxygen is removed from the ores by the gases and less by solid carbon; hence lower fuel consumption.

My own practice goes to prove that a furnace rapidly driven works with greater regularity and gives a more even quality of iron, lower in silicon, than a furnace slowly driven. However much some may disagree with fast driving, every furnace manager in Europe whom I have seen for the purpose of this inquiry, whilst professing to be satisfied with the output he had already attained, was at the same time making some addition or alteration whereby he expected to obtain increased production and diminished cost.

Mr. Carnegie is so satisfied with the great economy of the results he has already obtained that he is constructing four more furnaces, and in a few weeks will have two of them in operation at his Duquesne Works near Pittsburg. The results of the working of these furnaces will be eagerly watched by all European and American engineers. The following are the leading particulars of this installation, which is to cost about £600,000. Height of furnace 100ft., bosh 22ft. diameter, angle of bosh 74 deg., crucible 14½ft. diameter, throat 17ft., bell 12½ft., ten tuyeres 8in. diameter, placed 9ft. 8in. above the level of the hearth. There are to be five pairs of blast engines, of vertical compound condensing beam type, having high-pressure cylinder 40in. diameter and low-pressure cylinder 78in. diameter, two air cylinders 76in. diameter and 5ft. stroke; the ordinary speed is to be 40 revolutions per minute, at which speed each pair of engines will deliver 25,000 cubic feet of air per minute at from 16 lb. to 18 lb. pressure per square inch; the maximum speed will be 50 revolutions, and maximum pressure of air 25 lb. A production of 500 tons in twenty-four hours is expected from each furnace, being at the rate of 180,000 tons per annum; and if the lining endures only four years of such work, the satisfactory quantity of 700,000 tons will be obtained, a quantity which an English furnace would require fourteen years to produce. There are twenty-four Babcock and Wilcox 250-horse power boilers, with two steam drums for each boiler, 36in. diameter and 23¼ft. long, and 126 tubes 4in. diameter and 18ft. long; the tubes are arranged in fourteen sections per boiler, nine tubes in each section. Each furnace has four Cowper-Kennedy stoves, with central combustion chamber, height 96ft., diameter 21ft. Every appliance for saving labour, and every improvement which their great experience has shown, will be adopted. Whilst generally in America the whole labour cost per ton of Bessemer pig iron is from 80 cents to one dollar, it is reported that this new plant will reduce the cost nearly one half.

One more example of the working of an American smaller plant. Furnace, 77ft. high; bosh, 19ft. diameter; crucible, 11ft.; six tuyeres, 6in. diameter; four Massicks and Crookes stoves. Production last year, 81,780 tons, or 220 tons per day, of Bessemer pig iron from Lake ores. Ore, 3940 lb. per ton of iron; coke, 2060 lb.; limestone, 780 lb. Total labour cost, 1·05 dol.

Germany and Luxemburg come next in production. The average of the three years 1881-2-3 was 3,254,844 metric tons of all descriptions of pig iron; and the output increased each year, till in 1894 it amounted to 5,345,632 tons, and in 1895 to 5,431,007 tons, being an average of about 28,000 tons per coke furnace per annum in the Dortmund and Bonn districts. Stimulated by the adoption of a protective tariff and by the invention of the dephosphorisation process of steel making, Germany rapidly developed all her industries, and enjoys great and increasing prosperity. Luxemburg contributes a large quantity of pig iron to German steel works, besides supplying important quantities of Minette ironstone. At Esch, in the Grand Duchy of Luxemburg, there are four blast furnaces in operation, making together about 800 tons of basic pig iron per day, which is sent by railway 120 to 150 miles to Westphalia at the low carriage rate of 10f. per ton. This blast furnace plant of the Société de Luxembourgeois is considered the most important in that region. For the last month the furnaces made their largest average of 202 tons per day, using Westphalian coke containing about 8 per cent. of ash, and Minette ironstone, the best in that district, with Greek manganiferous ore to reduce sulphur, and additions of basic slag to give phosphorus up to 2·2 per cent. A new furnace is being constructed, and will be put into operation this autumn; the height is 82ft.; bosh, 23ft. diameter; angle, 73 deg.; hearth, 11½ft.; throat, 15ft. There is much dust in the furnaces, and it is supposed to lie on the boshes, forming a protection to the brickwork, and so water cooling plates are said to be of no practical advantage. In order as much as possible to prevent the dust from passing into the stoves, there are six tubes 8ft. 2in. diameter and 66ft. high, resting in a pan of water; the dust passing alternately down and up these tubes has time to deposit itself in the water, and is scraped out without stopping the blast. Five Cowper stoves, 83ft. high and 23ft. diameter, heat the blast to 900 deg. C. or 1650 deg. Fah. Seven tuyeres of 7in. diameter. For these high stoves a powerful draught is absolutely necessary. The chimney is 270ft. high and 11½ft. diameter at the outlet. A horizontal compound condensing engine, making twenty-four strokes per minute, supplies 22,000 cubic feet of air at 7 lb. pressure per square inch, with steam at 6½ atmospheres; high-pressure cylinder 52in. diameter, low-pressure 78in., air cylinders 100in. diameter, stroke 5ft. 3in. They have never succeeded in getting these cylinders to work without cooling them with water. For the new furnace a vertical compound condensing engine is being constructed at Bayenthal.

At Uckange, in Lorraine, on the Moselle, there is a smaller and well arranged new plant of three furnaces, two in operation, each making about 123 tons per day. The furnaces use Minette ironstone containing from 33 to 34 per cent. of iron, obtained from their mines about two miles distant. A new furnace in course of construction and nearly completed is 65ft. high; bosh, 19½ft. diameter; hearth, 9ft. 9in. Four tuyeres of 7in. diameter. Four Cowper stoves 62ft. high, 21¼ft. diameter. Directly after leaving the furnace the gas is conveyed to a receiver of large diameter, the bottom part of which is tapered to receive a valve easily opened for discharging the dust thus collected. The gas is further passed through ascending and descending wrought iron tubes of considerable height and diameter, and by lowering its speed gives time for more dust to become deposited on the surface of the water receptacle below; the mud thus obtained can then be easily scraped out. By these means the large proportion of the dust is prevented from entering the stoves and boilers. There are three vertical compound blast engines.

At Ruhrort I found the largest German production, the output at two furnaces for the thirty-one days of last month—March—was 16,800 tons from ores averaging 40 per cent. of iron. The furnace was said to be 88ft. high, but the useful height would probably be nearer 80ft. Bosh 21½ft. diameter, angle 63 deg., protected by several water blocks; hearth, 12½ft. diameter. Eight tuyeres of 7in. diameter; nozzle pipes red-hot by daylight; pressure of blast, ¾ atmosphere. Four Cowper stoves 98ft. high and 26ft. diameter. The furnace was lined with carbon bricks up to the boshes only; the bricks are thus kept well below the region of carbonic acid gas, and so far are doing well. A Bayenthal compound condensing vertical blast engine, running at forty-five revolutions per minute, drove one blast furnace. It was said that this engine could run well at sixty revolutions per minute; but with the complicated cut-off gear, such a speed would soon necessitate considerable repairs. The air cylinders were 78in. diameter with 6ft. stroke.

Another set of eight blast furnaces in that district—seven in blast producing together 25,000 tons per month of basic foundry pig, ferro-manganese containing up to 80 per cent. of manganese—whilst working fairly well, offered nothing specially favourable to record, except that, being fully alive to keep to the front, they have just erected and nearly completed the first of eight pairs of horizontal compound condensing blast engines, having air cylinders 80in. diameter and 5ft. stroke; and whilst the manager expressed himself satisfied that 150 tons per day of basic iron is ample for a furnace, he is providing sufficient blast-power to give 200 tons. The Minette ironstone from Luxemburg costs 3s. 6d. per ton, and carriage 6s. 6d. This is mixed with Swedish Grängesberg ore, containing 60 per cent. of iron and 1 per cent. of phosphorus, costing 15s. 6d. f.o.b. at Ruhrort; and with puddlers' tap-cinder from England. The basic pig iron so produced, containing 0·5 per cent. of silicon and 2 per cent. of phosphorus, is conveyed to a 120-ton mixer, where the sulphur is reduced to a very low percentage by the addition of manganese. The whole of the 18,000 tons of steel produced monthly at these works is made by the dephosphorisation process; indeed very little acid steel is now made in Germany, the former being preferred.

At Mr. Fried Krupp's works at Essen, both acid and basic steels are made; but Mr. Asthöwer informed me the best steel made in their large crucible shed is manufactured from puddled iron—a somewhat despised material to-day—which is selected and cut up in suitable pieces for the crucibles. In this large casting-house they make four casts of crucible steel every day of twenty-four hours. Crucible castings up to 80 tons are made from twenty-three Siemens above-ground furnaces, which hold 100 crucibles containing 50 kilos. each. All the castings of varying weights that I examined looked perfectly solid and free from blow-holes. All rails, plates, and girders are made by the dephosphorising process, either Bessemer or Siemens. The shop containing the forging presses, plate-rolling mill, &c., is a magnificent structure. The plate mill has forged steel rolls 4ft. diameter and 13ft. long, driven by a pair of horizontal reversing engines geared 2½ to 1, the rolls making about thirty-two revolutions per minute. I saw a deck-plate rolled from an ingot 20in. thick, and reduced to 2in. in twelve minutes. Some plates for boilers lying on the floor, 12 tons weight, measured 45½ft. long, 11½ft. wide, and 1¼in. thick, made to form the complete circle of a boiler. An ingot mould to receive an 80-ton charge measured 11½ft. by 36in. by 13ft. deep. Mr. Krupp owns twelve blast furnaces, and will commence building at Rheinhausen eight of modern type, each to make 180 tons per day; three are to be at work next year. The blowing engines are to be of the same pattern as those at work at Micheville in France, described later on.

My friend, Mr. Consul Hoesch, is building some blast furnaces at his steel works near Dortmund. My powers of description will give only an inadequate idea of the magnificence of this installation. The works are laid out for four furnaces, two of which, commenced last July, are erected, and will be in operation this summer. The coal for coke-making is washed and crushed, and stocked in capacious bunkers, placed sufficiently high for it to flow into small wagons with bottom doors for charging through apertures in the tops of the ovens. The Coppée coke ovens, with some improvements by Dr. Otto, are arranged at one end of the works in two groups of fifty each. The bye-products, consisting of sulphate of ammonia, oils, and pitch, are obtained; and the cleaned gases are utilised for heating the walls of the ovens and raising steam. Each oven produces four tons of dense coke per twenty-four hours, at a cost of about 10s. per ton. The coke is conveyed by overhead railway to the blast furnaces. The ores are stocked in exceptionally large and numerous bunkers, each 230ft. long and 33ft. deep, entailing a heavy first outlay, because the Swedish ore can be obtained from the Lulea region during five months only of the year, owing to the mines being frozen up during the rest of the year. This ore is estimated to cost about 17s. per ton at the works. The two furnaces, are 75ft. high, 21ft. bosh, rising 18¾ft., angle 75 deg., crucible 10½ft. diameter, 8ft. 2in. high, throat 14ft. 8in., central tube for taking off the gases with two downcomers, six tuyeres of 5in. diameter Ten Cowper stoves, 92ft. high, 21¼ft. diameter, with chimney 245ft. high, outside diameter at bottom 16¼ft. and at top 10¾ft. Twenty-four Lancashire boilers 7ft. 2in. diameter, 34ft. long, two tubes each 30in. diameter without cross tubes, heating surface 95 square metres or 1020 square feet. The two furnaces, placed 114ft. apart from centre to centre, have separate hoists and roofed cast houses; and the hearth level is high enough above the general level for the slag and molten iron to flow into cast iron boxes and ladles, to be conveyed to the heap or to the steel works. For the two furnaces there are four compound condensing horizontal blast engines, with high-pressure cylinder 42in. diameter, low-pressure 60in., air cylinders 75in., and stroke 5½ft., to make from thirty-five to forty revolutions per minute. Steam pressure 8½ atmospheres, and blast pressure from one-half to one atmosphere, as may be required. The 100 coke ovens with bye-product plant are estimated to cost £75,000; the two blast furnaces, with all railways, bunkers, &c., £150,000.

At a works where the production of pig iron was very large, the cost of labour was as low as 1s. 9d. per ton. The total cost, including general and establishment charges, was only 3s. 3d. per ton.

In 1882 the production of Bessemer iron was 733,665 tons, and it has fallen now to 350,000 tons; whilst in 1883 the production of Thomas iron was 369,685 tons, and it has constantly and regularly increased, till it has now reached the enormous total of 2½ million tons. Germany is entitled to the highest credit for her skill, industry, and perseverance in this rapid and great development of the basic dephosphorisation process of steel making. This unexampled success has enabled her to use her own phosphoric minerals to an important extent, and to produce a material used for every purpose, where the highest quality is an absolute necessity.

France follows with an average output in the three years 1881, 1882, 1883, of 2,000,000 metric tons, which declined in 1886 to 1,516,574 tons, and gradually increased to 2,005,889 tons in 1895, when there were seventy furnaces in blast, giving an average of about 30,000 tons per furnace per annum. The furnaces in the centre, South, and North of France making Bessemer pig iron have made little, if any, progress for some years; but great impetus was given to the production of phosphoric pig iron in the East of France by the invention of the dephosphorisation process of steel making. In the Meurthe and Moselle district there are forty-three blast furnaces, which produced last year 1,264,000 tons, being an average of 30,000 tons per furnace per annum, leaving only 813,647 tons for the whole of the remaining furnaces of the country. Engineers in the whole of the Lorraine and Luxemburg districts have paid great attention to blast furnace construction and production; they state that they consider the essential points to be borne in mind for regularity of working and large production are, that every furnace should have numerous Cowper stoves, and should have its own blast power isolated from that of other furnaces. Their most economical and best results have been attained, firstly, by increased size of furnace; secondly, by higher temperature of blast; thirdly, by more powerful blast engines.

The ironstone used is the well-known minette, of three qualities—red, grey, and calcareous. These either by themselves, or mixed with one another, require neither additions of limestone in the furnace nor calcination. The ironstone in the neighbourhood of Longwy averages a little over 30 per cent. of iron. The coke is brought from Westphalia, a distance of more than 150 miles, and costs delivered 21·30f. per ton; the price into wagons in Westphalia is 10f., and the duty 1·30f. per ton. Labour cost per ton of iron varies from 25d. to 30d. The class of iron made throughout this district is mostly Thomas iron, that is, pig iron run into cast iron moulds for the Bessemer basic process, made specially low in silicon so as to contain only about 0·5 per cent.; and in order to make it high enough in phosphorus, namely, to contain about 2 per cent., an addition of phosphoric slag from the converter is necessary, as the minette by itself gives only 1·5 per cent. of phosphorus. Greek ore is also added to give about 1·8 per cent. of manganese in the iron, so as to keep the sulphur down to about 0·6 or 0·8 per cent., the iron being white. Generally, from 1150 kilos. to 1200 kilos. of Westphalian coke is required for making 1000 kilos. of iron. The forge and foundry iron is almost identical in character and analysis with Cleveland iron.

At Micheville two furnaces have recently been put in blast, which are excellent types of good construction. By the courtesy of Mr. Ferry, I am able to give the following description:—Height of furnaces, 80ft.; bosh, 22ft. diameter; angle, 72 deg.; hearth, 10ft.; throat, 16¼ft. diameter. This large diameter of throat enables capacious charging apparatus to be used, and the charges are exceptionally heavy, consisting of coke 5½ tons and ironstone 15 tons, or 1200 kilos. of coke to 1000 of pig iron. There is no greater economy found in heavy over light charges, except that the apparatus is opened less often, and there is consequently less loss of gas. A disc valve of about 16ft. diameter is lowered on the ridge of the apparatus to prevent the escape of gas when the materials are being lowered into the furnace, but as it is difficult to make so large a valve quite gas-tight, there is some escape, though not very considerable. There are only four tuyeres at work, though provision is made for seven. The average production is nearly 150 tons per day. There are four Cowper stoves to each furnace, 80ft. high and 23ft. diameter. Two pairs of vertical compound condensing blast engines, made by the Société Alsacienne of Mulhouse, are of excellent design, strongly made, and of good workmanship—high-pressure cylinders, 36in. diameter; low-pressure, 50in.; air cylinders, 78in. diameter; stroke, 5ft., and 32 revolutions per minute. The governor is adjustable to give the number of revolutions fixed upon by the manager, the pressure of the blast being disregarded. As there is not far away from the blast furnaces a steel works producing 10,000 tons of steel per month, which will soon be increased to 12,000 tons, the engineer, Mr. Hartmann, has paid the closest attention to the economical use of the furnace gases, with the view of working the engines in the whole of the works without using coal under the boilers. There are in all at Micheville four blast furnaces, producing about 3500 tons per week; one is open-topped, that is, there is a central tube taking off sufficient gas to work the blowing engine and Cowper stoves in connection with the furnace, and the remainder of the gas is allowed to escape. When the whole of this gas is utilised by cup and cone arrangement, and six more boilers now nearly ready for work are completed, there will be seen at Villerupt a steel works having a pair of vertical compound Bessemer blowing engines for the basic converters, a compound condensing cogging mill engine, a compound condensing rolling mill engine with three-high billet and bloom and slab rolls, all of which, with all the small engines, will be supplied with steam from the blast furnace gases, after these have heated the hot-blast stoves and worked the furnace blowing engines. The boilers have large combustion chambers below the level of the floor, and are of the multitubular kind, having 208 square metres or 2240 square feet of heating surface, and the tubes are so arranged that they can be brushed out whilst the boiler is at work. A thin layer of blast furnace dust deposited in the tubes largely curtails the power of the boilers to produce steam; six hours without cleaning shows a marked difference in the quantity of steam raised; two men are therefore constantly employed in brushing out the tubes of twelve boilers The gases escape from the boilers at a temperature of 280 deg. C. or 540 deg. Fah., and after passing through Green's economisers, are reduced to 160 deg. C. or 180 deg. C., or 320 deg. Fah. or 360 deg. Fah. The steam pressure is eight atmospheres.

The ingots are taken as hot as possible from the Bessemer department, placed in Gjers soaking pits, in which a small quantity of coal is used, and then rolled off. An English order for basic billets 2¼in. square has just been completed, and delivered in Antwerp at 103f. per ton, a distance of 150 miles, at a cost for carriage, wagon hire, &c., at 7f. per ton. The labour cost per ton of pig is 2·80f., and the total cost 40f. per ton. The cost varies in different districts; the Westphalian syndicate having different prices for coke for different districts, all calculations of costs are rendered most complicated and difficult. The molten metal is conveyed direct from the blast furnaces to a mixer of 120 tons capacity, and from there to three basic converters some distance away.

At the Aciéries de Longwy Mont St. Martin there is an important plant of half-a-dozen blast furnaces, with steel works, having three 15-ton basic converters and extensive rolling mills. Whilst the materials produced are of a high character, there is nothing of special importance to call for attention.

Belgium.—The average production per annum for the years 1881-82-83 was 711,705 metric tons, which declined in 1891 to 684,126 tons, and afterwards increased, till in 1895 the production was 816,039 tons from thirty furnaces in blast, the average output per furnace being about 27,000 tons. The production is still increasing. Although poor in iron ores, Belgium is advancing in blast furnace practice, and intends to hold a leading position.

The Société John Cockerill has constructed in the best possible manner, and just put into operation, a very fine blast furnace installation, having all the most recent improvements. By the courtesy of Mr. Greiner, Director-General of the Company, I had the pleasure of being present at the starting of the furnace on the 30th of last month—March—when the Minister of Public Works travelled from Brussels to light the fire, and wished success to the furnace, and increased commercial prosperity to this most successful company, and to the material interests of the Kingdom of Belgium—an instance of the great interest taken by the Government in the development of the industries of the country. The furnace is 78ft. high, bosh 20ft. diameter, angle 71½ deg. There are five tiers of water blocks above the tuyeres to protect the lining of the boshes. Hearth 10ft. diameter at the bottom, widening to 11ft. at the level of the tuyeres. Seven tuyeres of 5in. diameter, placed 9ft. apart from nose to nose, and 6¼ft. high above the level of the hearth. Throat 15ft. diameter, having two gas outlets to one large downcomer, which leads into a capacious receptacle containing water for cleaning the gases. Four Cowper stoves, lined with octagonal bricks, are 82ft. high and 22ft. diameter; the chimney, with wrought iron casing lined with bricks, is 230ft. high, with a clear outlet of 10ft. diameter.

One of the blast engines is a copy of a type adopted at some American works. It has two outside fly-wheels, an arrangement which makes it difficult to reach readily some of the working parts. It is a single vertical quick-running engine, with air cylinder 84in. diameter placed above the steam cylinder, which is 42in. diameter. The maximum steam pressure is six atmospheres, and the valve gear has somewhat complicated motions for early cut-off. The stroke is 5ft., and the speed forty revolutions per minute, with the intention of running up to sixty; if found desirable the pressure of blast may be increased to one atmosphere. A second engine is being constructed of better design, and of greater power and more strongly made, consisting of a pair of vertical compound condensing engines, with a single large fly-wheel in the centre of the shaft; high-pressure cylinder 30in., low-pressure 48in., two air cylinders each 68in. diameter, stroke 4ft., to make from forty to sixty revolutions per minute; and pressure of air from 7 lb. to 10 lb. per square inch. Great attention has been given to the boilers; they are 9ft. 10in. diameter, and have each three tubes; the two top tubes are 3ft. 3in. diameter, and the bottom one 2ft. 8in.; length 32½ft. The boilers are fired by the gas from the furnace; and each tube has a separate chamber of large capacity, to ensure complete combustion. Westphalian coke is used. The ores are principally Tafna, Rubio, and purple, all low in phosphorus, for making Bessemer pig iron. From the ordinary furnaces about 100 tons are obtained daily; and from the new furnace much better results are expected, probably 200 tons a day.

At the works of La Providence, Marchienne, Mr. Hovine has two furnaces in operation, and a new one is being constructed. Those at work each produce 110 tons daily of basic pig; and the new one, which is larger, is expected to give 140 tons daily. There are altogether seven furnaces in operation making phosphoric pig iron, the steel works using nothing but basic pig. These works are celebrated for the low prices at which they export girders, &c., to England. A rolling mill having three-cylinder engines was rolling girders in a three-high train at a high speed, direct from ingots heated in coal-fired furnaces. The labour cost per ton of Bessemer iron is 2½f.; 4f. cover all kinds of labour and salaries; and another franc is found a sufficient fund for re-lining. Labour at basic furnaces is 3f. per ton of iron, little, if any, limestone being used. Belgium, having last year reduced its tariff, has commenced to complain of Germany throwing some of its surplus production into the country at very low prices.

Several other blast furnaces are being constructed abroad, but sufficient has been said to show that they recognise the vital importance of obtaining suitable and cheap pig iron; great efforts are being made and large sums of money expended to produce it in greater quantities and at lower costs. From the foregoing figures of production and descriptions of plant, it can be seen that great progress is being made abroad, whilst our production of pig iron, compared with the average of the three years, 1881-82-83, remains stationary. America has doubled her output. Germany and Luxemburg are increasing so rapidly that probably this year will see their output also doubled, and they are steadily and rapidly advancing to our figures. France remains stationary. Belgium has increased 13 per cent.

Fuel.—With respect to our position as regards fuel, the cost of coal varies considerably in the several regions; but the following figures of values, supplied to the Secretary of the Board of Trade by Sir R. Giffen, indicate pretty accurately the relative costs of production in the five countries, and show that, as regards Germany, our costs are alike, but are considerably lower than those of France and Belgium. In 1894 the United Kingdom and the other countries here mentioned produced the following quantities of coal of the average values named per ton at the pit:—

United Kingdom	produced	188,277,000	tons at	6s. 8d.	per ton.
United States	,,	158,000,000	,,	5s. 3¼d.	,,
Germany	,,	76,741,000	,,	6s. 7¼d.	,,
France	,,	26,964,000	,,	9s. 0¼d.	,,
Belgium	,,	20,534,000	,,	7s. 5½d.	,,

Iron ores.—Swedish phosphoric and Spanish hematite are somewhat dearer on the Continent than with us; but the minette ironstone costs only about 2s. per ton at the mines, whilst similar ironstone at home costs more, being burdened by a royalty charge of about 6d. per ton.

Railway rates.—We have seen that low railway rates abroad permit of carrying low qualities of ironstone to furnaces 150 miles distant from the mines, and also of carrying coke from Westphalia to the Luxemburg, French, and Belgian blast furnaces to make pig iron, and afterwards of carrying the pig iron made in Luxemburg and Lorraine to Westphalia to be converted into finished products. In this country it must be admitted that we have a splendid railway service, and that the dividends paid are only fair and reasonable; but the rates of carriage are out of all proportion heavier than those ruling abroad.

Labour cost.—As regards the labour cost per ton of iron, there is not much difference to our disadvantage; so that it is misleading to accuse ourselves of inability to compete from this cause. But there is no doubt whatever that our labour has become far more difficult to manage, is much more ready to stop work in order to obtain an increase of wages, and is constantly agitating for fewer hours of work. Every concession made renders it more and more difficult to compete with the Continent in the markets of the world; but our workmen cannot yet be brought to see this, neither can they be persuaded to cease opposition to mechanical devices for saving labour and reducing costs; indeed, all such appliances are jealously watched, and if possible their success is prevented. Yet the favourite remedy for this state of things in many minds is to spread technical education all over the country; whereas, if the result they desire could unhappily be attained, the last state of the trade would be worse than the first, for we should have no hewers of coal nor makers of steel. The truth is that there is no lack of technical ability in this country; quite the contrary. Our continental competitors do not claim to have invented the puddling process, the rolling mill, the steam hammer, the Bessemer acid and basic processes, the hot blast stove, &c.; but they have carefully applied all these processes and inventions of ours to their own use, in a scientific and practical manner; and we are equally free to adopt their methods, if any of them are better than our own. But they can and do claim that they have trained skilful, careful, and obedient workmen. Whilst I do not concede that a continental workman understands his duties better than our workmen, I do most distinctly believe that his military training has been of great advantage to him, to his physique, and to his employers. A compulsory strict military training, to follow the sound and excellent education now given to every one, would contribute greatly to the general good of our country. Our path is strewn with difficulties; but the greatest difficulty we have to surmount, which seems insurmountable, is the barrier of tariffs set up against us. For, whilst Great Britain is free and open to attack from all the world, America demands a payment of 16s. 8d. for every ton of pig iron we send there, Germany 10s. per ton, France 15 francs minimum; and Belgium, brave little kingdom, surrounded by powerful competitors, reduced its duty in July of last year from 5 to 2 francs. In these tariffs lies the real reason of the success of foreign competition; but we have no right to complain, for these barriers have enabled those countries to develope their resources and to employ their own population. But we do complain when, after having supplied their own requirements at prices that leave them good profits, they throw their surplus products into our country and into our Colonies at lowered prices. Remove these barriers, and then the reproachful cries we are fond of raising against ourselves—of want of technical knowledge and ability, want of energy and enterprise, and decadence of our industries—would become cries of the past; and the race for supremacy would be a race run on its merits.

SOCIETY OF ENGINEERS.

AT a meeting of the Society of Engineers, held at the Royal United Service Institution, Whitehall, on Monday evening, May 4th, Mr. G. Maxwell Lawford, vice-president, in the chair, a paper was read by Mr. Arthur Rigg, past president, on "Hydraulic Rotative Engines."

The paper was devoted to the subject of "Hydraulic Rotative Engines," and took no account of any other class of hydraulic motor. Comparison was made between the great literary interest given to turbines, and the paucity of such interest concerning hydraulic engines; also between the great attention devoted to economising steam, and the little that has been done towards economising pressure water, which as a source of power is far more costly than steam.

The author next proceeded to describe all the principal types of hydraulic rotative engine by Armstrong, Westmacott, Brotherhood, and many others. This historic portion of the paper was followed by a theoretical examination of the variations which occur in the tangential driving efforts of different kinds of engines, illustrated by diagrams, and these showed how the peculiar behaviour of some of these engines can be accounted for. The loss of useful effects by contracted passages was next noticed, and the last portion of the paper was devoted to the theory and construction of the revolving cylinder type, together with the author's improvements whereby hydraulic engines are now constructed so that they can be governed automatically, so that they no longer need to use the full amount of water as if working to their maximum power, when doing little or nothing, but are governed for the first time in the history of hydraulic engines, so as to work with an economy as scientific and complete as any steam engine.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Chief engineer: Edwin J. Austen, to the Intrepid, to date April 28th. Engineers: Charles R. Hall, to the Vernon, additional; Henry S. C. Baldwin, to the Active; and Richard W. Martell, to the Intrepid, to date April 28th. Probationary assistant engineer: George H. Scullard, to the Intrepid, to date April 28th.

THE INSTITUTION OF CIVIL ENGINEERS: NEWCASTLE-UPON-TYNE ASSOCIATION OF STUDENTS.—The annual business meeting was held in the Durham College of Science, Newcastle-on-Tyne, on Wednesday, the 29th ult., when the following were elected Council for Session 1896-77:—President: John Bell Simpson, M. Inst. C.E.; past presidents: Philip J. Messent, M. Inst. C.E.; Henry H. Wake, M. Inst. C.E.; J. Watt Sandeman, M. Inst. C.E.; Charles A. Harrison, M. Inst. C.E.; Hon. Charles A. Parsons, M. Inst. C.E.; vice-presidents: J. Dobson Wardale, M. Inst. C.E.; J. Rae Baterden, A.M. Inst. C.E.; William J. Cudworth, A.M. Inst. C.E.; T. Dawson Ridley, Assoc. Inst. C.E.; E. W. de Russett, M. Inst. C.E.; members: R. E. Beavis, Stud. Inst. C.E.; A. Cole, Stud. Inst. C.E.; R. F. Drury, Stud. Inst. C.E.; G. H. Hellas, Stud. Inst. C.E.; A. G. Mackinlay, Stud. Inst. C.E.; honorary secretary, C. C. Markham, Stud. Inst. C.E., Cleveland-terrace, Darlington.

INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND—PREMIUM AWARDS.—At the closing meeting of the thirty-ninth session of the Institution of Engineers and Shipbuilders in Scotland which was held last week, the members voted premiums of books, of the value of £5 in each case, on account of three very excellent papers that were read during session 1894-95. One of the premium awards was to Professor W. H. Watkinson, M. I. Mech. E., of the Glasgow and West of Scotland Technical College, on account of his paper on "Water-tube Boilers;" another was to Mr. W. Carlile Wallace, formerly engineering partner of Messrs. Blackwood and Gordon, shipbuilders, Port Glasgow, and now a responsible member of the staff of Sir John Brown and Co., Sheffield. His paper was on "The Electrical Transmission of Power in Shipyards and on Board Merchant Steamers." The third award was to Mr. James M. Gale, M. Inst. C.E., a past president of the Institution, and engineer to the Glasgow Corporation Water Commissioners. Mr. Gale's paper was on "The Extension of Loch Katrine Waterworks." In former years, Mr. Gale read other papers on those works, the first of which has become a sort of "classic" in connection with waterworks engineering, and on account of it he received the Institution Gold Medal. On this occasion neither it nor the Railway or Marine Engineering Medal was awarded for any of the 1894-95 papers.

THE INSTITUTION OF JUNIOR ENGINEERS.—At a meeting of this Institution, held at the Westminster Palace Hotel, on April 17th, a paper on "Dredgers" was read by Mr. W. J. Hunter, member. The chair was occupied by Mr. H. B. Vorley, vice-chairman. In dealing first with the question of design, the author gave as the principal affecting considerations:—(*a*) Whether the dredger was required to work in smooth water or in a sea way. (*b*) The draught of water available to commence operations. (*c*) The depth of water to which the dredger was to work. (*d*) Mode of delivery of spoil, whether by ordinary shoots into barges alongside, by a travelling belt, by means of pipes, or over the stern by a travelling belt or a long shoot. After indicating the merits and objections of single and double ladder dredgers, and of open and closed wells, a description was given of the usual type of engine employed. It was very necessary to fit the bucket driving gear with some sort of friction apparatus, arranged to give way when any heavy obstruction was encountered. The shape and make of the buckets, and of the top and bottom tumblers and parts of gearing, were next considered. The second part of the paper contained particulars of construction of ordinary bucket ladder dredgers, of hopper dredgers, and of other classes of dredgers, including sand pump, grab, pneumatic, land, and spoon and bag. Reference was also made to machines for unloading barges by means of a bucket ladder with dredger action. Detailed descriptions followed of two dredgers presenting novel features, built by Messrs. Hunter and English, one for the Peruvian Corporation, and the other for the Leeds and Liverpool Canal Company. The cost of dredging was shown to vary with conditions of working, instances being given of a light-draught dredger in Spain, 1·8d. per cubic yard; on Lake Copias, Greece, with coal at 45s. per ton, 1·3d. per cubic yard; on the river Trent, 0·34d. per ton, the price in each case not including first cost of dredger and depreciation. A discussion followed the reading of the paper.

TESTS OF A 10-HORSE POWER DE LAVAL STEAM TURBINE.*

THE de Laval steam turbine experimented upon constitutes a part of the permanent equipment of the Engineering Laboratory of Purdue University, and the present paper is based upon data secured chiefly through the assistance of Charles E. Bruff, B.M.E.†

I.—DESCRIPTION OF THE ENGINE.

In the de Laval steam turbine, jets of steam, delivered from suitable nozzles, are made to impinge against the buckets of a light turbine wheel. The steam enters the buckets from one side of the wheel, and passing through, is discharged or "exhausted" from the opposite side. The arrangement of nozzle and wheel is shown by Fig. 1. The motion of the turbine shaft, which, under the action of the jets, is extremely rapid, is communicated by gearing to a heavier and slower moving driving shaft carrying a fly-wheel of small diameter; from this wheel the power of the engine is delivered. Regulation of speed is secured by means of a throttling governor, which controls the pressure of the steam admitted to the nozzles.

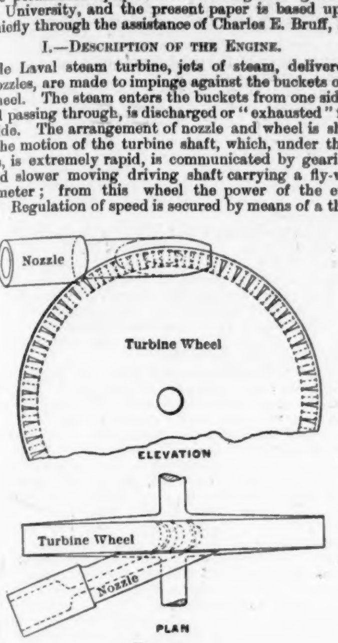


FIG. 1.

The important moving parts, with approximate dimensions, are shown by Fig. 2. The turbine wheel is built up of sixty-three steel segments, each carrying a bucket and a portion of the light outside rim. The segments are held in place by means of suitable collars, which grip them on either side. The wheel is mounted upon a long, slender shaft, having sufficient flexibility to allow the system at speed to revolve about its centre of gravity, even though this may not agree with the geometrical axis of the shaft. The gear upon the turbine shaft is of steel, solid with the shaft; that upon the drive shaft has its teeth formed in a bronze ring, which is carried by a solid iron centre. The smaller gear has twenty-one teeth, the larger one two hundred and eight teeth, giving a ratio of 1 to 9·90476.

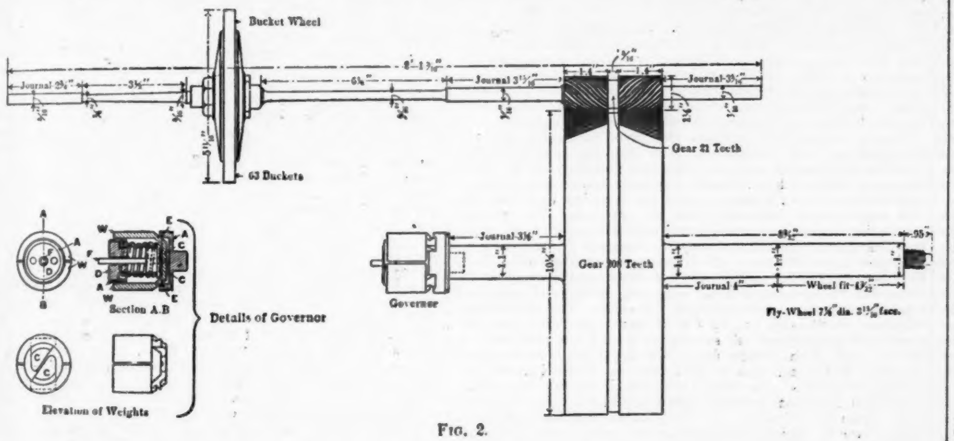

FIG. 2.

The shafts run in bronze boxes completely lined with Babbit or other soft metal. To assist in the distribution of oil, a spiral curve, the pitch of which is about half the diameter of the journal, is cut into the metal of the bearing. The outboard bearing on the turbine shaft is closed at the end, and a small pipe runs from the closed end to a point over the gears. The pumping action, resulting from the presence of the spiral oil-way, gives a constant, though small, supply of oil upon the gears. The gears do not dip in oil, though the case which encloses them receives drainage from all the bearings.

The governor is connected with the driving shaft, of which, at first sight, it appears to be but an extension. It is shown in detail in Fig. 2. The weights W W, with their arms C C, are in the form of a split cylindrical cup. Upon the outside and at the base of each weight a knife edge E E is formed, which bears upon a suitable surface in the governor frame A A. A spiral spring is fitted at its inner end with two projecting pins, which bear upon the arms C C of the governor weights. The outer end of the spring is connected with the frame by the threaded plug D. When the governor is at rest the concave surfaces of the weights are in contact with the frame, and the tension of the spring keeps the knife edges upon their seat. When the governor is revolving at speed the weights are under centrifugal action and move outward, swinging upon their knife edges, against the resistance of the spring. The motion of the weights is taken up by the pin F, by which it is communicated, through suitable mechanism—not shown—to the governor valve above the engine.

The nozzles, which serve to deliver steam to the wheel are four in number, and are so fixed in the frame of the engine as to act upon the turbine wheel at points which are equally distant from each other. Two of the four are provided with stop-cocks, which, when closed, put out of action the nozzles with which they are connected. By means of the stop-cocks, therefore, the engine may be run under the action of two, three, or four nozzles, at the will of the engineer.

The distinguishing feature of the engine, perhaps, is to be found in the form of the nozzles. All are diverging, the throat or smallest diameter being approximately 2in. from the discharge end. Three have a diameter in the throat of 0·138in., and one a diameter of 0·157in.

It is assumed that the form of the nozzles is such that the pressure of the steam as it passes from the orifice will be that of the surrounding medium, and, since the flow is nearly adiabatic, it is clear that if this condition is realised all the energy of pressure is transformed into energy of motion before the steam is allowed to impinge upon the buckets of the turbine wheel. The medium surrounding the nozzles in the machine is practically that of the exhaust, so that the expansion from the pressure of the boiler to that of the exhaust is complete before the steam has contact with any moving part of the machine.

Lateral motion of the driving shaft is limited by contact between the large gear and the bearings on either side. With this shaft fixed, the double spiral of the gears makes lateral motion of the turbine shaft impossible. All forces, therefore, tending to displace the turbine wheel laterally are transferred to the slow-moving shaft, where ample rubbing surfaces can be provided without seriously impairing the efficiency of the machine through frictional losses—a happy solution of an otherwise difficult problem. When it is remembered that the parts shown—Fig. 2—are those of a machine capable of developing 10-horse power, that the driving shaft under normal conditions makes 2500 revolutions a minute, and the turbine shaft practically ten times as many, the opportunity for the display of good design and workmanship may be better appreciated. Viewed as a piece of mechanism, the engine tested appears to merit high commendation, both as to design and workmanship, but the service which has thus far been obtained from it is not sufficient to show the effect of long-continued use.

II.—THE TESTS.

Arrangements for testing.—The power of the engine was absorbed by a Prony brake, cooled by constant streams of water. The exhaust steam was piped to a Wheeler condenser, open to the atmosphere. The water resulting from condensation was drained into tin buckets, which were changed and weighed at regular intervals.

Gauges were used to show the steam pressure both above and below the governor throttle, the former giving the pressure available at the engine, and the latter the pressure under which, in consequence of the action of the governor, the steam was admitted to the nozzles. A manometer was also attached to the exhaust pipe, but as this pipe is large—3in. diameter—and the connection with the condenser close, the observed pressure was never appreciably different from that of the atmosphere.

Conditions and results.—The boiler pressure for all efficiency tests was 130 lb. by gauge, for which pressure the particular nozzles used were designed. The rated speed of the fly-wheel is 2400 revolutions per minute—23,771 for turbine wheel—but this standard was not maintained for all the tests. The governor was adjusted several times as the work progressed, and it was not until several tests had been run that the proper speed was secured. It is believed, however, that the differences of speed recorded do not materially affect the value of results for purposes of comparison.

The tests are grouped into three series, the first including those for which all four nozzles were in action, the second those with three, and the third with two. The several tests in each series were intended to vary from each other only in amount of power delivered from the wheel. All tests were of thirty minutes' duration, and all observations were taken at five-minute intervals. The conditions of each test were maintained with such uniformity that the observations of any five-minute interval were very nearly identical with the average of all observations taken for the test.

The observed and calculated results appear in tabulated form below, Table I.:—

TABLE I.—*A Summary of Results of Tests.*

Nozzles.	Number of test.	Revolutions per minute of belt wheel.	Brake horse-power.	Steam pressures by gauge. In boiler.	Steam pressures by gauge. In engine below governor valve.	Total pounds of steam per hour.	Pounds of steam per brake horse-power per hour.
All four nozzles in action, three having a diameter in throat of 0·138in., and one a diameter in throat of 0·157in.	1	2138	0·00	130	17·1	120·8	—
	2	2545	1·63	130	42·2	210·3	128·6
	3	2038	2·36	130	48·5	230·8	99·8
	4	2118	2·97	130	55·6	254·6	85·7
	5	1917	3·46	130	61·9	275·5	79·6
	6	2072	4·38	130	70·8	313·0	71·5
	7	2128	5·10	130	76·9	328·5	64·4
	8	2576	7·52	130	99·6	403·0	53·6
	9	2453	8·24	130	104·4	422·8	51·3
	10	2411	10·33	130	126·3	491·8	47·8
Three nozzles in action, two having a diameter in throat of 0·138in., and one a diameter in throat of 0·157in.	11	2584	0·00	130	31·3	121·4	—
	12	2112	3·95	130	83·6	267·8	67·8
	13	2125	4·77	130	93·4	286·0	60·0
	14	2490	6·50	130	111·7	346·3	53·3
Two nozzles in action, each having a diameter in throat of 0·138in.	15	2546	0·00	130	42·2	99·3	—
	16	2049	1·95	130	83·5	162·6	83·4
	17	1909	3·43	130	121·1	222·9	65·0
	18	2412	3·87	130	127·0	229·6	59·3

It will be seen that, with all four nozzles in action, and with the engine developing a little more than its rated power, the steam consumption per horse-power per hour is as low as 47·8 lb. In comparing this result with results obtained from other engines, the small size of the engine tested—10-horse power—should be kept in mind, and also the fact that the rate of consumption stated is based upon brake power. The efficiency of the engine falls off rapidly as the load is decreased, and, as would be expected, the effect is most marked when all the nozzles are in action. This may best be seen by means of three heavy-lined curves given in Fig. 3. Assuming the nozzles to be cut out of action one at a time, as soon as the reduction of load becomes sufficient to permit the work to be done without them, the minimum steam consumption at different loads for the boiler pressure and speed employed is represented by the broken line *f g d e b c*, Fig. 3. Again, if instead of four nozzles, an infinite number could be employed, and if the governor could be arranged so as to regulate the number in action, rather than the pressure admitted to them, the steam consumption of the engine in question might be made to follow a line somewhat similar to the light broken line *g e c*. But the heavy lines indicate the results which were actually obtained.

The engine requires very little attention and is almost noiseless in action. The governor is quick to act, and its speed regulation appears to be fair, except when changes of load are large and suddenly made. After such a change, the engine requires a little time before settling down to steady running under the new conditions.

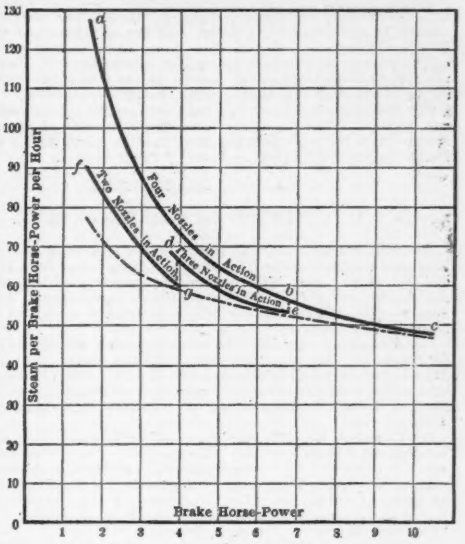

FIG. 3.

Starting power.—As the speed of the de Laval engine is high, it is evident that the force in action must be comparatively low. To determine the maximum resistance under which the engine might be expected to start, the brake was clamped upon the fly-wheel so that the latter could not turn within it. Steam was then admitted to the engine, and readings were taken from the scale under the brake arm. The result of this process, of course, depends upon the steam pressure and the number of nozzles in action. With all nozzles, and with a steam pressure of about 125 lb. by gauge, the maximum starting power is equal to a force of 30 lb. acting at a radius of 1ft. The following tabulated data—Table II.—gives the starting power for different pressures, and when two, three, or four nozzles are in action:—

TABLE II.—*Starting Power of Engine.*

	Four nozzles in action.		Three nozzles in action.		Two nozzles in action.	
Steam pressure by gauge. ..	125·2	71·1	125·2	71·1	125·2	71·1
Effective radius of brake arm, feet..	1·5	1·5	1·5	1·5	1·5	1·5
Reading of scale under brake arm, lb...	20·0	12·1	14·1	9·0	9·5	6·0
Equivalent force in pounds, acting at a radius of 1ft.	30·0	18·2	21·2	13.5	14·3	9·0

SUICIDES IN THE ENGINE-ROOM STAFF OF THE MERCANTILE MARINE.

A MEMORANDUM recently issued by the Registrar-General of Shipping and Seamen deals with the question of suicides in the engine-room staff of the mercantile marine.

In this report the Registrar-General states that it is only since the beginning of 1892 that the system has been in full working order by which officers at the ports at home and abroad hold a special inquiry into cases of deaths of firemen and trimmers reported to have committed suicide or as missing at sea, and that the memorandum is confined to deaths from above causes of firemen and trimmers which occurred since 1st January, 1892, on vessels registered under the Merchant Shipping Act in the British Islands.

An analysis of the reports of the inquiries of the officers shows that thirty firemen and trimmers serving under ordinary agreement, and nineteen Asiatic firemen and trimmers serving on vessels trading to the United Kingdom under "Asiatic" agreement—*i.e.*, special agreements terminating in India or China—committed suicide or are supposed to have committed suicide in 1894, as against twenty-seven and fourteen respectively in 1893. The figures also show that but few suicides occur in the home or coasting trade, where the voyages are short and a man feeling unwell can remain on shore.

As regards the foreign going trade, the suicides occur in no very marked degree in any particular locality, nor can it be said that suicides occur with frequency on a particular vessel or line of vessels. It should be noted, moreover, that no suicides are reported to have occurred in the record-making mail steamers running between the United Kingdom and the United States. It appears that the suicides cannot be attributed to ill-usage either by their superiors or fellow workmen, the reports in all cases being to the effect that there was no ill-treatment.

The heat of the stokehold and coal bunkers is undoubtedly very great, running in some cases to 120 deg. Fah., but to give any comparative table on this point would be misleading, as the temperature is not taken upon any system. It also appears from the reports that the number of deaths occurring either when the man was actually drunk or suffering from delirium tremens, or from the effects of a recent drinking bout, including those suffering from mental derangement, was twelve in each of the years 1894 and 1893; and the conclusion would appear to follow that the prevalence of suicide amongst firemen may to some extent be attributed to the necessity of turning to work in a hot stokehold whilst still suffering from the effects of drink.

The proportion of suicides to number employed is—as in the case among the general population—larger among the men over thirty than amongst the number under that age.

With regard to the question as to what are the number of firemen and trimmers employed in the mercantile marine of the United Kingdom amongst whom these suicides occur—when an attempt was made to obtain the numbers employed on the 5th April, 1891, on merchant ships registered in the British islands, it was found that on that day there were actually serving as firemen and trimmers—not including Lascars—on these vessels the following numbers:—

In the home trade	4,207
In the foreign trade	17,258
In the fishing trade	399
Yachting	97
	21,961

These figures—allowance being made for variation in tonnage employed—represent approximately the numbers at sea at any one time; and the total strength of the whole body of firemen and trimmers required for the mercantile marine service is obtained by adding a certain proportion to cover the number of men on shore.

The Registrar-General calculates that the rate of suicide amongst firemen and trimmers in the mercantile marine is about 1 in 900. Suicide amongst stokers in the Royal Navy is very rare. The Registrar-General concludes his report as follows:—"There can be little doubt that the figures as regards 'suicide' or 'supposed suicide' fairly represent the actual condition of things, and that though the rates of suicide I have given, based as they are on estimates, may be criticised, no amount of criticism will obscure the fact that suicide amongst firemen in our mercantile marine service is prevalent to a degree, calling for serious attention."

The rate of suicide amongst all males between the ages of twenty and fifty-five, which practically cover the active life of seamen, appears from the reports of the Registrar-General of Births and Deaths to be about 1 in 5000.—*Board of Trade Journal.*

THE INSTITUTION OF GAS ENGINEERS.

A GENERAL meeting of the Institution of Gas Engineers will take place on Wednesday, Thursday, and Friday, the 13th, 14th, and 15th of May, 1896. The first two days' meeting will be held at the Institution of Civil Engineers, Great George-street, Westminster, S.W. The third day will be devoted to a visit to the Hastings Gas Works.

On Wednesday, May 13th, the following papers will be read and discussed:—(1) "Notes on Residuals," by Chas. Hunt. (2) "The Efficiency of the London Argand at different rates of Gas Consumption, with Special Reference to its use as a Gas Testing Burner," by Lewis T. Wright. Annual Dinner at the Holborn Restaurant at 6.30 for 7 p.m.

On Thursday, May 14th, the chair will be taken at 10.30 a.m. Reading and discussion on the following papers:—(3) "Incandescent Gas Lighting," by Vivian B. Lewes. (4) "Gas, its Measurement in Relation to Temperature.—A Question for Consideration," by George Livesey. (5) "The Application of the Expansion of Fluids to the Correct Measurement of Gas," by W. Fiddes. (6) "Coal Gas Enrichment," by A. F. Browne.

On Friday, May 15th, at 9.0 a.m. the members will leave Charing Cross Station, South-eastern Railway, by the 9 a.m. train—or Cannon-street 9.5—in saloon carriages, by fast train to Hastings, *viâ* Ashford, where the first stop is made. Leaving Ashford 10.42 the train proceeds through the romantic south-eastern corner of England, passing Romney Marsh, Dungeness, the ancient cinque Port of Rye, the ruins of Camber Castle, and picturesque Winchelsea. On arriving at Hastings the party will proceed to the gas works—ten minutes' walk—where they will be received by the engineer and his staff, and conducted over the works. The Hastings Gas Works possess many points of interest, not only from their situation now, but as an example of works which have been re-constructed several times on the same site, as enlargement became necessary. At the present time the works are in a state of transition for an ultimate make of three million cubic feet per day. Attention may be directed to the gasholders, which have all been erected recently, and to No. 3 in particular, which has a steel lining placed inside the original C. I. tank, owing to the W. I. bands surrounding it having given way and being very difficult to replace. This holder has an original type of guide framing, and the inner lift of the holder rises above this. Carburetted water gas plant is also in course of erection, on somewhat novel lines, as regards arrangement. There is also a small but complete electrical installation, sulphate of ammonia works, special apparatus designed for dealing with naphthalene troubles or enrichment, a complete laboratory, and new offices and show rooms. The retorts are all 22in. by 16in., oval D 20ft. long, set in beds of sixes, which give very good results, but it is ultimately proposed to fit up No. 3 house with machinery and regenerative furnaces. The coal used is principally Newcastle, being shipped to Whitstable, conveyed thence by rail, and carted into the works. Owing to the geographical position of Hastings and the town dues on coal, it is expensive compared to other similar towns. After the inspection the members will be entertained to luncheon by the Directors of the Hastings and St. Leonard's Gas Company, in the new offices. After luncheon conveyances will be ready to proceed for a drive along the extensive sea front to West St. Leonard's, and round the charming country at the back of the town, returning along the Ridge through the old part of Hastings and fishing quarter, along the front to the Hastings pier, fifteen minutes' walk from the station. 6.0 p.m., train leaves Hastings, *viâ* Tunbridge Wells, due Charing Cross 9.7 p.m. 7.15 p.m., train leaves Hastings, *viâ* Tunbridge Wells, due Charing Cross 9.23 p.m.

LAUNCHES AND TRIAL TRIPS.

On the 1st inst. Messrs. Wm. Simons and Co., Renfrew, launched from their yard the last of the three steam hopper barges recently ordered by the Admiralty. It is of the following dimensions:—Length, 160ft.; breadth, 28ft. 6in.; depth, 12ft. 6in.; and has a hopper capacity for 570 tons of dredgings. This vessel was launched with all her machinery on board complete with steam up, and will in a few days leave for H.M. Dockyard, Devonport, where she is to be employed. Messrs. Hay, Stewart, and Scoggins, Admiralty overseers, represented the Admiralty at the launch.

Earle's Shipbuilding Company, Hull, has made a further addition to the Stettin and Copenhagen line of Messrs. Thomas Wilson, Sons, and Company, of its town, in the shape of a fine steel screw steamer, named the Zero. She is 250ft. long, 30ft. beam, by 18ft. 1in. moulded depth, and being intended for the carriage of butter and other perishable cargo, she is fitted with a Hall's patent refrigerating plant, and her main hold insulated and converted into a cold storage chamber. The vessel has a topgallant forecastle and a long poop, in the latter of which there is accommodation for twelve first-class passengers, besides quarters for the captain, officers, and engineers. The machinery is of the three-crank triple-compound type, with cylinders 18½in., 31in., and 53in. diameter, by 33in. stroke, and two boilers to work at 200 lb. steam pressure.

On Friday, May 1st, there was launched from the Cleveland dockyards of Sir Raylton Dixon and Co., Middlesbrough, a fine steel screw steamer, which has been built to the order of The Hamburg South American Steamship Co., for its passenger and general traffic to Rio Grande, under the supervision of Mr. F. G. Dietze. This is the first of two sister ships which these builders are now constructing for the same owners. The vessel is of the spar deck type, and has been built under special survey for Bureau Veritas highest class, the principal dimensions being:—Length, 310ft. 6in.; beam, 41ft. 2in.; depth moulded, 26ft.; with a deadweight carrying capacity of about 3960 tons on a light draught. The accommodation for first-class passengers is under the bridge, with dining saloon in house on bridge deck, all of which will be handsomely fitted up. Commodious and well ventilated quarters for about 326 emigrants are also provided aft in poop and 'tween decks. The decks are sheathed with teak, and all the fittings and accommodation are of a particularly complete and first-rate description. Triple-expansion engines will be supplied by Messrs. Thos. Richardson and Sons, Hartlepool, having cylinders 20in., 33in., 57in. by 45in. stroke, with two large boilers working at 205 lb. pressure. The steamer on leaving the ways was named Taquary by Mrs. R. H. Harkness, of West Hartlepool.

On Thursday, 30th ult., Messrs. Batram and Sons, of Sunderland, launched a large finely-modelled steel screw steamer for Messrs. John Herron and Co., of Liverpool. The vessel is of the spar deck type, with long bridge covering engine and boiler openings, poop, and topgallant forecastle. The following are the principal dimensions:—Length, 350ft.; breadth, 45ft.; depth moulded, 26ft. 9in.; with a carrying capacity of 5200 tons on a very light draught of water. There are six water-tight bulkheads, and the double bottom will contain about 800 tons of water ballast. The vessel is built on the deep frame principle, the hold beams being dispensed with; and the holds being particularly clear of all obstructions, and suitable for general cargoes. The deck machinery consists of six large steam winches by R. Welford, direct-acting steam windlass by Emerson, Walker, and Co., one of Riley Bros.' multitubular donkey boilers, and steam steering gear by John Lynn. The saloon and captain's room are at fore end of the bridge, and are handsomely fitted up in polished hardwood. The accommodation for officers and engineers is placed at the aft end of the bridge. The crew have comfortable quarters in the forecastle, and the poop is fitted for light cargoes. The engines will be supplied by Messrs. J. Dickinson and Sons, the cylinders being 24in., 31½in., 65in. by 42in. stroke, with two steel boilers 15ft. 6in. by 10ft. 3in., 160 lb. working pressure. In addition to the usual machinery there will be an evaporator and feed-heater, steam ash hoist, duplex feed and ballast pumps, and other modern appliances. The vessel and her machinery are being superintended during her construction by Messrs. Flannery and Gritton, consulting engineers, of Liverpool and London. As the vessel left the stocks she was named Lord Kelvin by the Mayoress of Sunderland.

At Renfrew, on April 29th, there was launched complete from the works of Messrs. Wm. Simons and Co., a large and powerful twin screw hopper dredger, constructed to the order of the Crown Agents for the Colonies, for the Government of Ceylon. It is for service at Colombo Harbour works, and was built under the direction of Messrs. Coode, Son, and Matthews, consulting engineers, Westminster, Mr. Wilson Wingate, N.A., being inspecting engineer. Its dimensions are as follows:—Length, 216ft.; breadth, 40ft.; depth, 15ft. The hopper compartments are provided on each side of well, and have a joint capacity for 900 tons dredgings, having all the necessary gear for lifting and lowering the hopper doors by steam and hand. The vessel is also adapted for loading barges of large capacity on either side when required in addition to filling its own hopper, the upper tumbler being high enough to allow sufficient angle for shoots to fill the barges when the dredger is fully loaded. The buckets have a capacity of eighteen cubic feet each, and the bucket ladder works in a central well capable of dredging to a depth of at least 36ft. under water level when the vessel is light, and the angle of the ladder does not exceed 45 deg. The weight of the bucket ladder, with buckets and mountings complete, is about 170 tons. It is propelled by two sets of triple expansion engines driving twin screws of 1000 combined indicated horse-power, and has two boilers of mild steel constructed for a working pressure of 160 lb. per square inch. An auxiliary boiler is also fitted in the stokehold to work the deck machinery when under repair. Powerful triple barrelled steam mooring winches are provided at bow and stern, each barrel working independently or conjointly as required. Steam hoisting engines are provided for lifting the bucket ladder, and also for raising the hopper doors, two independent sets of steam steering gear. Double geared anchor cranes of special construction are fitted at bow and stern. Awnings are fitted on deck fore and aft. The cabins for officers and crew are comfortably fitted up, with separate rooms for the officers, and bath rooms attached. The timber fittings throughout the vessel are of teak. On leaving the ways she was named the Sir John Coode, by Mrs. Coode, wife of the senior partner of Messrs. Coode, Son, and Matthews, whose father, the late Sir John Coode, was the founder of that well-known firm of civil engineers.

Messrs. Joseph L. Thompson and Sons, of the North Sands Shipbuilding Yard, Sunderland, have just delivered two finely modelled steel screw steamers, the Maria Rickmers and the Ellen Rickmers, to the order of Messrs. Rickmers Reismuhlen Rhederei and Schiffbau A. G., Bremen, which are intended to run in the rice trade mainly between China and Bremen. The general description of the vessels is as follows:—427ft. long, 50ft. 6in. wide, and 30ft. deep, moulded; and they are designed to carry a deadweight of over 7200 tons, with Lloyd's summer freeboard. They have been built under special survey to Lloyd's highest class, on the three deck rules, and have a full poop, long bridge, and topgallant forecastle. The poop is arranged for cargo. The officers' and engineers' berths are on the top of the bridge deck, and the passengers' state rooms and saloons are placed in a house built on the fore part of the bridge deck. On top of this house is placed the chart and wheel houses. The crew are berthed in the topgallant forecastle. The vessels are built on the web frame principle, with intercostal stringers right fore and aft. The upper and main decks are of steel, the poop, bridge, and forecastle decks being of wood. Special attention has been paid to the loading and discharging arrangements, nine derricks being fitted, six of which are of steel. Seven powerful steam winches are placed on deck at the hatches, and a patent steam windlass on the forecastle deck. The steam steering gear is placed at the after end of the engine room, and is controlled by a wheel from the steering house on the bridge forward. All the auxiliary machinery is arranged to work at the full boiler pressure. A powerful screw gear is placed at the after end of the poop. Water ballast is carried in a cellular double bottom, right fore and aft and in the after peak. The vessel is fore and aft schooner rigged, with pole masts. On the upper bridge deck amidships are placed four large boats, the two lifeboats being of seamless steel. The vessels have a graceful clipper stem finished off with a well carved figurehead, and elaborate trail boards running away from this. The engines for the Maria Rickmers have been supplied by Messrs. George Clark, Sunderland, and are of the following sizes:—27in., 43in., and 72in., with a stroke of 46in. Steam is supplied by four multitubular boilers, working at 180 lb. pressure; and all the most modern improvements in propelling machinery are fitted. The engines for the Ellen Rickmers have been supplied by Messrs. John Dickinson and Sons, Sunderland, and are of the same sizes as the above, but with three boilers only. In this vessel, Howden's system of forced draught have been adopted. The vessels, after running a most satisfactory trial, proceeded to their loading berths, and are now on their first voyage to the East. The two vessels attracted a considerable amount of interest in shipbuilding circles while being finished at the works of the builders, and are notable additions to Messrs. Rickmers' well-known fleet.

THE NEWPORT HARBOUR COMMISSIONERS' WEEKLY TRADE REPORT.

THE demand for steam coal is good, and stems are fairly filled. The shipments for the past week reached nearly 90,000 tons. Prices are firm. House coal shipments are fairly good, with prices unchanged. Tin-plates steady, with moderate inquiry. The iron and steel works in this district are fully employed.

Coal: Best steam, 8s. 3d. to 8s. 6d.; seconds, 7s. 9d. to 8s.; house coal, best, 10s.; dock screenings, 5s.; colliery small, 4s. 6d.; smiths' coal, 6s. 6d.; patent fuel, 10s. 3d. Pig iron: Scotch warrants, 46s.; hematite warrants, 47s. 5d. f.o.b. Cumberland; Middlesbrough No. 3, 37s. 5d. prompt; Middlesbrough hematite, 45s. Iron ore: Rubio, 12s.; Tafna, 11s. 3d. Steel: Rails, heavy sections, £4 12s. 6d.; light ditto, £5 f.o.b.; Bessemer steel tin-plate bars, £4; Siemens tin-plate bars, best, £4 2s. 6d.; all delivered in the district, cash less 2½ per cent. Tin-plates: Bessemer steel, coke, 9s.; Siemens, coke finish, 9s. 3d. Pitwood, 15s. 3d. to 15s. 6d. London Exchange telegram: Copper, £45 8s. 9d.; Straits tin £59 16s. 3d. Freights, firm.

THE IRON, COAL, AND GENERAL TRADE OF BIRMINGHAM, WOLVERHAMPTON AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE works were reported on 'Change in Birmingham to-day—Thursday—to be steadily engaged, and the improved Cleveland stock returns also assisted the market. Values remain much the same as a week ago. The attendance on 'Change was more limited than usual, many of the chief ironmasters being away at the Iron and Steel Institute meeting.

In finished iron, marked bars are £7, with 12s. 6d. extra for special brands; merchant bars are £6 to £6 5s.; and common bars, £5 5s. to £5 7s. 6d. The weakness in sheet iron values continues. Black sheets are quoted: singles, £6 7s. 6d.; doubles, £6 10s. to £6 15s.; and lattens, £7 15s. Hoop and thin strip are £6 7s. 6d.; angles are £5 15s.; stamping sheets are £9 10s.; and best thin sheets, £11. Galvanised sheets have strengthened with the advance in spelter, and are now about £10 5s. for 24 gauge, f.o.b. Liverpool.

Steel is in good request at £5 10s. for basic girders and angles, and £6 5s. for boiler plates. Siemens' blooms and billets, £4 15s.; Bessemer, £4 10s.; bars, £5 15s. to £6; sheets, £7 5s. to £7 10s., and angles and boiler plates, £5 12s. 6d. to £5 17s. 6d.

Pig iron prices are slightly firmer. Northampton forge pig is 40s.; North Staffordshire and Derbyshire, 41s. to 42s.; and Lincolnshire, 42s. to 43s.; Staffordshire all-mine is 55s.; part-mine, 40s. to 44s., according to quality, and cinder pigs, 35s. 6d. to 37s. 6d. Cold blast pig is 90s.

Engineers and machinists have plenty of work on their books, and the heavy ironfounders are well employed. For boiler, bridge, and general constructive works there are contracts on hand that will keep the men engaged for several weeks.

The annual meeting of the Birmingham gun trade has passed a report showing the number of barrels of all kinds proved at the Birmingham Proof-house during the year to have been 328,791, as compared with 299,273 in 1894, and 335,271 in 1893. The total amount received for barrels proved during the last three years has been:—1895, £3866; 1894, £3284; 1893, £3629. The chairman, in moving the adoption of the report, said that during the latter half of the past year there had been a considerable improvement in the gun trade, as shown by the number of barrels proved, there being an excess of 29,518 over the previous year. The exports of small-arms during the year showed an increase of £29,073. Reference was made to the proposal of the Armourers' Club of London to extend their operations so as to include the Gunmakers' Association, and it was understood that the matter would be brought up at one of the ensuing monthly meetings of the Proof-house.

In a communication to the South Staffordshire Institute of Iron and Steel Works' Managers, Mr. Thomas Morris, of Warrington, commenting upon the subject of foreign competition in the iron trade, has the following:—"The man is untruthful who says the continental puddler is as good as the English puddler, or who says the hammerman can shingle the iron better than our men; in fact, he is not truthful if he says any workman, through the whole gamut of them in the forges and mills, can equal the workman in Great Britain. Our orders leave us and go abroad to them in 99 cases out of 100 not because of better finish or better quality, or better education, but because the furnaces are kept going continuously 144 hours per week, as against our 128 to 130, and that not continuous; the puddler in Germany working for about half the wages the Staffordshire puddler gets, in Belgium for 2f. 35c. per 1000 kilos.—about 2s. for the English ton—or a little less than one-third the Englishman gets; and all others whom we term skilled workmen being paid at similar rates."

Rates of freight charged by German and United States lines to South Africa are compared with those charged by English lines by a special committee of the Wolverhampton Chamber of Commerce. It is shown that, as the result of the English shipping ring, and its agreement with the shipping companies of Germany, manufacturers of hardware in Remscheid can send their goods at 19s. 7d. per ton cheaper to Delagoa Bay than can manufacturers in Wolverhampton, and manufacturers of hardware in Berlin 21s. 6d. per ton cheaper. German competition is felt most at Delagoa Bay and north of that port, to which ports English rates of freight are practically prohibitory. For instance, the rate of freight for hardware from Wolverhampton to Tanga—German East Africa—is 75s., and the rate from Remscheid 43s. 4d. English goods to such ports are being shipped *viâ* Hamburg. The completion of the railway from Beira to Bulawayo and the development of the goldfields in Rhodesia may open up an immense trade for the Midlands, but the committee fear that German manufacturers will reap the chief benefit, the rate of freight from German manufacturing districts to Beira, the port of Rhodesia, for hardware, being 43s. 4d. against 75s. from Wolverhampton to Beira. As a result of the dissatisfaction of shippers, a joint committee of merchants and shipowners was formed some years ago to discuss all matters relating to rates, but it has been barren of results. The committee regard as increasing and serious the diversion of trade from British manufacturers which is being occasioned by the advantages derived from rates of transport not by the manufacturers of Germany alone, but by those also of America.

NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

Manchester.—The position generally throughout the iron trade here remains one of quietude as regards new business. Users, as I have previously stated, are mostly well bought for actual requirements, and the present weak tone in the market is rather an inducement to hold off from further buying. At any rate, until after the Whitsuntide holidays it is not likely there will be much buying of any weight. Makers and manufacturers, although not just now replacing the contracts running out, are in the meantime holding on to late rates, whilst merchants and dealers, where business is offered, cut in with low second-hand parcels, with the result that transactions are few and difficult, except at under current quoted rates.

The attendance on the Manchester Iron Exchange on Tuesday was about an average, with again only a small inquiry stirring generally, and an easier tone in the market as regards some brands of pig iron. Lancashire makers are still firm at their late quotations of 46s. 6d., less 2½, for No. 3 foundry delivered Manchester, and are booking renewals of contracts without difficulty on this basis. District makers are also securing a moderate business at late rates, orders being reported in some cases as coming forward rather more freely; Lincolnshire remains at 41s. to 43s. for forge and foundry, and Derbyshire foundry at 46s. to 46s. 6d. net cash, delivered Manchester. Outside brands offering here could be bought at about 3d. under last week's quotations, good foundry, Middlesbrough, not averaging above 46s. 4d. to 46s. 10d. net cash delivered by rail Manchester, whilst Eglinton is readily obtainable through merchants at 46s. 6d., and Glengarnock 47s. 3d. net, delivered Lancashire ports, with about 2s. 3d. more for delivery Dock Quays, Manchester, but makers quote above these figures.

In finished iron a falling off in new business is reported, orders now coming forward not being sufficient to replace those running out. For Lancashire bars £5 10s. is the maximum figure, with North Staffordshire qualities still quoted £5 12s. 6d. to £5 15s. delivered here. Sheets continue weak, and are obtainable at £6 17s. 6d. to £7, but Association list rates for hoops are steady at £6 2s. 6d. for random to £6 7s. 6d. for special cut lengths delivered Manchester district, with 2s. 6d. less for shipment.

In the steel trade makers are doing a fair business, and firm at late quotations, but there is a good deal of underselling on the part of merchants and dealers. For No. 3 foundry hematite makers still hold to 58s., less 2½, as the minimum, but at this figure they are altogether out of the market for new business merchants being prepared to sell at 56s. 6d. to 57s., less 2½, delivered here. Steel billets still average £4 7s. 6d., with bars obtainable a trifle under £6, whilst boiler plates, although still quoted £6 7s. 6d. by makers, are still sold by merchants in odd lots at £6 5s., delivered here.

In the metal market the demand for all descriptions is fully maintained, with prices very firm at full list rates, and the probability of some advance on brass goods at an early date is bringing forward some extra inquiry in this direction.

The reports I receive generally from representatives of the engineering trades throughout this district still show activity well maintained in practically all departments, new work coming forward freely, especially amongst machine tool makers, stationary engine builders, and boiler makers, whilst the locomotive building firms are now throughout this district well supplied with work for some time to come. Of course the decided improvement which has come over the engineering industries during the present year is, as might be expected, giving rise to some agitation amongst the workmen for advances in wages. So far any actual movement in this direction is confined to a couple of engineering centres, the pattern makers in the Bolton district and the moulders in the Oldham district having brought forward the question of placing their wages on the same level as the rates ruling in Manchester. Hitherto it has been an understanding that in outside districts such as the above, the rate of wages should be on a lower scale than those which are paid in Manchester, and whether the movement for bringing the Bolton and Oldham wages up to the Manchester level will, if successful, be simply a prelude to a move for an advance in the Manchester district, so as to maintain wages there at their higher level, of course remains to be seen. The matter is at present, I understand, under the consideration of the Employers' Association, but nothing definite has yet been actually decided upon.

Messrs. Maybrick and Ashworth, of Dickenson-street, Manchester, are introducing a patent safety apparatus for application to hoists and elevators, the object of which is to prevent the hoist from moving further, in the event of the rope breaking, and so remove the risk of serious accidents. The invention consists of a governor which controls a wedge or brake, and which is so arranged that if the rope of the hoist breaks, the governor balls fly out, and bring the wedge in contact with the guides, and with an abutment on the case of the hoist, the friction of the wedge on the guide forcing the former in between the guide and the abutment, with the result that the cage is immediately stopped. A stationary rope is fixed in proximity to the path of the cage, which, passing over suitable pulleys, drives the governor by frictional contact when the cage is in motion, one of the pulleys being adjustable to impart the required tension to the rope. The arrangement is entirely automatic in action, being simply dependent on the working of the governor and wedge, and except in the case of accidents the hoist cannot descend at a greater speed than is desirable without being instantly stopped.

This week I had an opportunity of inspecting the new wells and pumping machinery put down by the Stockport and District Waterworks Company at their Wilmslow works, for the purpose of obtaining an additional water supply for the requirements of the above district. The works, which have been carried out under the supervision of Mr. T. Molyneux, the engineer to the company, consist of a well 9ft. inside diameter and 21ft. deep, lined with 14in. brickwork, with a concrete floor 18in. thick, into which is fixed a stand-pipe, to which the delivery pipes are bolted. From the bottom of the brick well there is a bore-hole 104ft. deep, 28in. diameter, lined with steel tubes of 25in. bore. From this depth there is a 14in. bore-hole unlined, 477ft. 3in. deep, making a total depth of 602ft. 3in. Messrs. Ebenezer Timmins and Sons, of Runcorn, the contractors, commenced their portion of the works in May, 1894, and when the depths of boring obtained were 450ft., 500ft., 550ft., and 602ft. 3in. respectively, tests were made of the approximate quantity of water available, and when the last-named depth was reached Messrs. Timmins were instructed to supply and fix a lift pump to raise from 750,000 to 1,000,000 gallons per day, together with the requisite engines for driving and all accessories. The engine is compound tandem, fitted with Proell's automatic expansion gear, made by Messrs. Marshall, of Gainsborough. The cylinders are 8in. and 14in. diameter, with a 22in. stroke, and the nominal horse-power is 35. The lift pump made by Messrs. Timmins is driven by a connecting rod from a crank on the mortice wheel shaft to a double L leg, to one end of which the ram of the lift pump is connected, the other carrying the balance weight. From the bottom of the ram the pump rods pass down the rising main to the bucket, which works on a gun-metal barrel fitted on top of the clack box. The working barrel is 18⅜in. diameter, and the stroke of the pump 4ft. 6in. The tank and river wall, which form the boundaries of the company's land, were built by Messrs. Fairbrother, of Hyde, the wall being 15ft. high from the rock foundation, and the tank, which is made of concrete, faced inside with brickwork, will hold 100,000 gallons. The water from the tank passes through a 12in. cast iron pipe to the well on the bore-hole in the old engine house, and is there distributed by three force pumps, including one by Messrs. Tangye, 12in. diameter and 3ft. stroke, capable of lifting 450,000 gallons per day against 180ft. head; one by Messrs. Pearn, of Gorton, 12in. diameter and 2ft. 6in. stroke, to lift 400,000 gallons against 180ft. head; and one made by Messrs. Mather and Platt, with three rams 4in. diameter, 8in. stroke, and capable of lifting about 100,000 gallons against 400ft. head. New mains have also been laid and arrangements made so that either of the two first-named pumps can be used to distribute the water in either portion of the district between Stockport and Alderley Edge. A new main is also about to be laid between Wilmslow engine house and the Alderley Edge reservoir. The engine house, engine beds, &c., were constructed by Messrs. Massey, of Alderley, and provision is made for the housing of a duplicate plant if necessary. A new boiler, 26ft. long and 7ft. diameter, to carry 120 lb. of steam, has also been constructed by Messrs. T. Oldham and Son, of Stockport, in order to provide the necessary additional steam power for the new plant. The whole of the boring operations have turned out satisfactorily, bearing out the opinion of Mr. C. E. De Rance, F.G.S., of the Geological Survey, and Mr. J. W. Gray, F.G.S., who were first consulted on the question of sinking, and the output of the new works is expected to reach about 1,000,000 gallons per day.

In the coal trade, although there is no real improvement to report, a steady tone is being maintained generally, due perhaps to a little extra buying going on here and there as a precaution on the part of consumers in the event of another possible stoppage of the pits. For house coals the demand is necessarily slackening off, but some of the collieries are still doing a fair business, which is keeping them, especially in the Manchester district, on about full time, and prices are pretty firm at late rates. This buying may to some extent be accounted for by consumers who would usually wait till winter before replenishing their cellars, ordering in supplies in order to make themselves secure against any possible contingency. Steam and forge coals are in no better demand, whilst prices continue excessively low, and it is still exceptional where more than 5s. 9d. to 6s. is got for good ordinary steam and forge coals, with 3d. to 6d. less taken on special sales. In engine fuel consumers seem anxious to get in stocks, and are placing some considerable orders, whilst there are fairly large inquiries stirring for forward contracts, which are evidently due to precautionary measures in the event of a dispute arising between the coalowners and the men. Prices show a hardening tendency, and although there is as yet nothing like any general upward move upon late rates, slight advances are here and there being got. At the pit mouth common slack still averages 3s. 6d., with best sorts 4s. 6d. to 5s. per ton.

In the shipping trade business continues quiet, with common round coals for steam purposes readily obtainable at 7s. to 7s. 3d., delivered Mersey ports.

Barrow.—The demand for hematite pig iron is well maintained, and the prospects of the immediate future are very assuring. It seems probable there will be a very brisk business throughout the year in Bessemer descriptions of metal, but the demand for forge and foundry iron is very quiet. Prices are easier at 47s. 8d. net cash warrant sellers, 47s. 7½d. buyers. Makers quote 49s. to 50s. for parcels of mixed Bessemer Nos., net f.o.b., and orders are very well held all round. There are 38 furnaces in blast as compared with 28 in the corresponding week of last year, but Messrs. Cammell and Co., Workington, are lighting forthwith the two furnaces they bought at Maryport owned by the old Solway Company. Then there will be 48 furnaces at blast, capable of producing practically 32,000 tons of metal per week.

Iron ore is in good request, and the demand for native as well as Spanish qualities is increasing. Prices, however, remain as previously quoted.

The steel trade shows activity in all its branches. Heavy rails are in good demand, and orders are very well held. Prices are steady at £4 15s. per ton for heavy sections. Plates for shipbuilding purposes are in brisk request, and makers are in a position to secure more orders than they can execute. As a consequence, prices are firm. In billets and hoops trade keeps good. West Cumberland makers are producing a deal of steel sleepers, and the makers in Furness are busy, amongst other things, on heavy steel castings.

Shipbuilders and marine engineers are looking forward hopefully for new orders, alike in commercial and Admiralty tonnage. The shipbuilding yards especially are in want of new work.

Coal is brisk at late prices, and coke is in steady and increasing consumption at stiffening values.

There is some talk of an early start being made in the development of the Walney salt deposit.

The traffics on local railways show a marked increase as compared with the corresponding half of last year, and this is one of the best evidences of how trade has improved lately.

Shipping shows more life this week. The exports from the West Coast this week represent 9218 tons of pig iron and 8602 tons of steel, as compared with 3015 tons of pig iron and 5132 tons of steel in the corresponding week of last year, an increase of 6203 tons of pig iron and 3470 tons of steel. The total shipments this year so far have reached 106,809 tons of pig iron and 147,239 tons of steel, as compared with 89,002 tons of pig iron and 119,879 tons of steel in the corresponding period of last year, an increase of 17,807 tons of pig iron and 27,360 tons of steel.

THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

AT this season of the year the collieries are working very moderately—four days a week being the average. Many of the thick seam pits are well employed, with the exception of those producing house and gas fuel, for which there is not much demand at present. During the week interest has mainly centred around the proceedings of the Miners' Federation and Conciliation Board meetings. Although no practical agreement has been arrived at, it is not expected that any great stoppage will occur, as in 1893. No improvement has taken place in the house coal trade. The summer-like weather now being experienced is seriously depressing that class of fuel. Lowest summer prices have now been reached, but little difference seems to have been made by this concession.

Quotations remain very much the same as when last reported, although there is a serious falling off in the prices asked for inferior qualities. Best Silkstone, 8s. 3d. to 9s. 3d. per ton; ordinary, 6s. 9d.; Barnsley house, 7s. 6d. to 8s. 3d.; Flockton, 7s.; and thin seam coal, 6s. per ton. Steam fuel is in better demand, the tonnage sent to Hull being well up to the average. Quite an average amount is being taken out of the district by the various railway companies, on contract account. Quotations: Barnsley hards, 6s. 6d. to 7s. 6d.; secondary sorts, 6s. per ton. Gas coal is in poor demand. Best qualities of manufacturing fuel are rather slow in sale, although the commoner qualities realise very freely. Small nuts, 4s. 3d. to 5s. 3d. per ton; screened slack from 3s. 3d. per ton; pit slack, 2s. 6d. per ton; and smudge, 1s. to 2s. per ton. Coke is in steady demand. All the ovens are well employed. Prices range from 8s. 6d. to 10s. 6d. per ton. for ordinary sorts, and 12s. for finest qualities.

The good trade which has been a feature of the heavy industries of the city for some months still continues, and with ever increased activity. The armour plate departments at all the works are working both night and day in executing Government orders. The railway material industry is also very encouraging. A large number of orders have come in both from home and abroad for tires, buffers, axles, springs, and other descriptions of railway goods. Pig iron is in increasing request, and a number of extra furnaces have been put into blast to meet the increased trade. As compared with the lowest value ever reached, prices have risen 5s. to 6s. per ton, and are very firm at current rates. Forge iron is selling at 40s. per ton, delivered in this city, while hematite iron, West Coast brands, realise 57s., and East Coast 54s. per ton. Good business is reported from all the steel, iron, and malleable iron foundries.

The chief demand in several of the lighter departments is for castings, for use in the cycle industry. The mills where employés are engaged in rolling wire for spokes report an excellent business. It is stated that every department connected with the cycle industry is extremely well off for work. A number of cutlers have disposed of their tools and gone to Coventry, Beeston, and other important cycle centres, to obtain better employment. In the majority of cases they have been successful in getting constant work, at higher wages than they could command in the cutlery and kindred trades of this district.

Manufacturers who produce lawn mowers, rollers, and similar garden tools, are well employed on late orders. Winter accumulations have been entirely disposed of, and it is expected that a better business will soon begin. Makers of disintegrating, grinding, separating, and screening machinery are full of orders, both on home and foreign account. Coal-washing machinery is also in satisfactory demand.

During the last month Messrs. Tasker, Sons, and Co., of Sheffield, have completed a specially designed machine for grinding armour plates. This piece of machinery has been ordered by Messrs. Krupp, the well-known gun, &c., manufacturers of Essen. The principle of the machine is not new, but Messrs. Tasker had to construct such a machine as would be capable of grinding chilled armour plates and similar heavy work. The machine is constructed in such a manner that either stones or the work can be made to travel. By means of an ingenious contrivance, the spindle carrying the disc can be raised from the horizontal line to an angle of 30 deg., thus enabling the angular edges of armour plates or other heavy pieces to be ground without their being moved. It can be operated either by electricity or the ordinary motive power. Messrs. Krupp's machine will be driven by electricity, the machine itself carrying the motor. The firm, who have protected themselves abroad, have several orders in hand for similar machines.

The lighter industries continue in the same sluggish condition. Cutlery in all its branches is but poorly inquired after, while the silver and plated trades are not much more satisfactory, except in the case of the larger establishments, who were heavily booked in the early part of the year. With a settlement in the Transvaal, the new market rapidly developing there for silver goods would soon become animated. Some excellent work for other parts of South Africa is now on order.

THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

NOTWITHSTANDING that the trade statistics are altogether favourable, that the consumption of pig iron is exceeding the production, and that the exports are continuing large, the iron market is dull and disappointing. The tone is flat and somewhat despondent, and sellers are more anxious to operate, while, as is natural in a falling market, consumers are not disposed to buy, especially for forward delivery, and nearly everybody has arranged for early needs. Thus there is next to no business doing. It is difficult to account for the present unsatisfactory condition of the market. Merchants and some of the producers have this week been selling No. 3 Cleveland G.M.B. pig iron, for May delivery, at 37s. 9d. per ton, but even that buyers have not readily paid, when warrants have dropped to 37s. 4½d. No. 1 Cleveland pig iron is at 39s.; No. 4 foundry at 37s. 3d.; grey forge at 36s. 9d.; mottled at 36s. 6d.; and white at 36s., all for early delivery; and forge qualities are not quite so scarce as they were.

Cleveland warrants are weak. Last month considerably more iron was lodged in Connal's public warrant stores than might have been expected, judging from the briskness in shipping and the activity at the finished ironworks. At April 30th the quantity of Cleveland iron in Connal's stores was 193,756 tons, an increase for the month of 6282 tons, whereas the increase in March was only 1964 tons, though trade was not quite so active, and the production was certainly no less. Of hematite iron Messrs. Connal and Co. at April 30th held 154,234 tons, the increase being 3455 tons for the month, against 5383 tons in March. The price of M. Nos. of Cleveland hematite pig iron is 46s. per ton for early delivery, but consumers are backward, as they hold that the output of this description of iron is in excess of the requirements, and still easier prices are not unlikely.

The Skinningrove Iron Company, whose works are situate on the sea coast near the extreme east of Cleveland, twenty miles from Middlesbrough, on Monday shipped its first cargo of Cleveland pig iron direct to the Continent, 561 tons being sent to Ternewzen in one of the company's own steamers. Previous to 1891 they had no facilities for shipping iron, but in that year they completed the construction of a jetty in the bay opposite their works, and since then have sent nearly the whole of their output to Scotland. The make since the blowing in of their two new furnaces has amounted to about 10,000 tons per month.

A well-known Middlesbrough firm of iron merchants has just imported a quantity of pig iron from Alabama. It has, however, been brought over on very exceptional terms, the freight being little more than a merely nominal figure, as the iron was put in as stiffening to a cotton steamer. In the ordinary course the freight would prevent the importation of such iron except at a considerable loss. If the experience of another Middlesbrough merchant firm is any criterion, this iron is not likely to be taken up by founders. The firm referred to last year imported some Alabama pig, and it is still on their hands in Liverpool, except a few sample lots. Consumers on this side have not taken kindly to it, as they say it does not suit their purposes.

It is reported that a firm of capitalists in London are negotiating with Sir Christopher Furness for the purchase of the blast furnaces at the Teesside Ironworks, and if these negotiations are carried through successfully, the new company which Sir C. Furness is to bring out shortly will be formed to carry on the engineering works of the late Teesside Company and those of Westgarth, English, and Co.

The April statistics of the Cleveland Ironmasters' Association must be regarded as satisfactory, for even the most hopeful did not look for a decrease of more than 2000 tons in the stocks of Cleveland iron, but the actual decrease was 5558 tons. This decrease is also important, as it is the first that has been reported since October last. Makers reduced their unsold stock by 14,012 tons, and they now have only about three weeks' production in stock, the total stock in the district being ten weeks' output, that is of Cleveland pig iron, no statistics being published as to the stock of hematite, &c., pig iron. The rate of production of pig iron was the same in April as in March, the 8854 tons decrease reported in April being due to the month being a day shorter than March. The total production for April was 266,096 tons, of which 133,756 tons was ordinary Cleveland iron—4468 tons decrease—and 132,340 tons hematite, basic, and spiegel pig iron—4386 tons decrease. Of the 134 furnaces erected in the North of England 95 were in operation, one less than in March, Messrs. Gjers, Mills, and Co., Ayresome Ironworks, Middlesbrough, having blown out a furnace for relining. Of these 95, there were 51 producing ordinary Cleveland iron, and 44 hematite, &c. The total stock of Cleveland pig iron at April 30th was 349,997 tons, of which 87,320 tons were held unsold by Middlesbrough makers (14,193 tons decrease); 10,821 tons held unsold by other makers in the North of England (181 tons increase); 31,830 tons were in makers' stores (1872 tons increase); 26,270 tons in the North-Eastern Railway Company's store (300 tons increase); and 193,756 tons in Connal's stores (6282 tons increase).

The shipments of pig iron from the Cleveland district during April were very good; they reached 105,470 tons—2560 tons more than in March, 1896, and 5310 tons less than in April, 1895. Satisfactory increases were shown to Germany, Italy, Norway, and Sweden. The exports for the four months of the present year have exceeded those of any previous year over the same period. They have reached 347,384 tons, and the nearest approach to this was in 1889, when 319,654 tons were despatched. As compared with last year, there is an increase of 61,941 tons, or 21 per cent. Never have either coastwise or foreign deliveries been so large. The following is the record for the past four years, and for the previous best:—

	Coastwise. Tons.	Foreign. Tons.	Total. Tons.
1896	187,120	160,264	347,384
1895	157,753	127,670	285,443
1894	182,470	130,159	312,629
1893	160,100	118,232	278,332
1889	176,031	143,623	319,654

Already this year 147,519 tons of Cleveland pig iron have been sent to Scotland, and 78,000 tons to Germany, or more than in any year since 1890. To Belgium also more was forwarded than in any year since 1890.

Messrs. Bell Brothers, the owners of the Clarence Ironworks, Middlesbrough, of several ironstone mines in Cleveland, and of the Tursdale, Page Bank, and Browney Collieries, have struck out an entirely new line with respect to their workmen—they propose to constitute themselves the savings bank for the men up to a certain point. Such of the men as desire it can leave a certain proportion of their wages each week on deposit in the hands of the firm—not less than 2s. a week. The firm offer to pay 5 per cent. interest on all deposits up to £50, and 2½ per cent. on all sums above that amount, as they do not desire to have large sums accumulating on their hands. The interest on every complete pound deposited will commence on the first day of the month following deposit, and will be calculated and added to the principal half-yearly, on June 30th and December 31st, at the rate of one penny per pound per month for the first £50, and a halfpenny per pound above that sum. The proposal is a unique one, and ought to stimulate their men to thriftiness.

There is no change of moment in the finished iron and steel trades, and quotations are maintained at the figures that have ruled for several weeks, but some of the manufacturers are more ready to accept small reductions therefrom. Common iron bars are firm at £5, less 2½ per cent. f.o.t. At Sir Theodore Fry and Co.'s Rise Carr Works, Darlington, three Siemens heating furnaces have just been completed, and two more are to be added. Puddled bars are at £3 7s. 6d., net at works. There is a good demand for bolts, nuts and rivets. Ships' rivets are sold at £7, and best boiler rivets at £8, less 2½ per cent. f.o.t. Steel ship plates are realising £5 2s. 6d., less 2½ f.o.t., and a good demand is expected to continue for them, as there is so much activity in the shipbuilding industry. Heavy steel rails are steady at £4 12s. 6d. net at works.

The River Wear Commissioners, out of ninety-eight applicants, have appointed Mr. Hilton T. Welford as superintendent of their chain, cable, and anchor proving establishment at South Dock, Sunderland.

The contract for straightening the Newcastle and Carlisle branch of the North-Eastern Railway, between the mouth of Blayden Burn and the staith of the Stella Coal Company, has been let to Mr. H. M. Nowell, of Leeds. The authorities at West Hartlepool are up in arms relative to the inadequacy of the passenger station accommodation in their town. Some improvements are being made, but it is contended that these will be far from what is needed, and they propose to follow the example of the Sunderland Corporation in having a Board of Trade inspector down to inquire into the matter. There has just been constructed at the North-Eastern Railway Company's locomotive shops one of the largest engines ever built. It has cylinders of 20in. diameter, and the piston stroke is 26in. The four coupled wheels are 7ft. 7¼in. diameter, and the weight of engine and tender is 90 tons. At a trial run on Friday the engine maintained a speed of 70 miles per hour without difficulty from Newcastle to Berwick. It is said that the engine has been built in preparation for a resumption of the railway race to the North next season.

The wages question in the engineering industry is beginning to give some trouble, indeed some of the men in the Tees district have already come out on strike, and it is feared that work will be interfered with in other parts of the North of England. The dispute has arisen because the employers refuse to concede to the machine workers connected with the Amalgamated Society of Engineers the same advance of wages as was conceded to the engineers. The strike of the men on the Tees will, it is said, involve the locking out of the engineers on the Tyne and Wear also. Thus the matter is serious, and is the more to be regretted as trade is getting into a satisfactory state. The joiners at the shipyards on the Tyne, Tees, and at the Hartlepools have had their wages advanced 1s. 6d. per week, and the labourers at the boiler and engine shops and the foundries in the North of England have also had their wages advanced generally 1s., now with a promise of 6d. more in September.

The Electric Lighting Committee of the Middlesbrough Corporation have had a report from Mr. Robert Hammond, of London, who had been requested to submit an expert opinion as to the advisability of installing the electric light for public purposes. As it was estimated that £21,000 would be required, the Committee decided to go no further at present. Stockton seems to be more in favour of electric lighting. It is said the cost would be £16,000 or £17,000, and the matter is under consideration.

The coal trade is somewhat improved as regards the steam coal branch, but it is very dull in other branches. A rumour is afloat that a local firm is about to buy a group of collieries in north Durham, but particulars are not yet ripe for publication. Coal shippers at Dunston Staiths complain greatly of the inadequate accommodation for loading coal, and in some cases steamers have to go to other places, as they are unable to get a berth. Coke is in good request, and the supply has improved now that the Brancepeth Colliery is in full work again, but it is hardly up to the requirements yet. About 13s. 9d. has to be paid for good coke delivered on Tees-side.

NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market was closed on Monday, in consequence of that day being a bank holiday in Scotland. On resuming next day, the tone of business was very quiet, but steady to firm. A good effect was produced by the monthly report of the Cleveland pig iron trade, which showed a reduction in stock, notwithstanding the large output. By its means prices hardened just a little; but the amount of business was too limited to carry this impetus very far. Scotch warrants sold at 46s. 4d. and 46s. 4½d. for cash, and 46s. 6d. one month; there has been only a small business since. In Cleveland warrants there have been very few transactions, the price for a part of the week standing nominally at 37s. 8d. cash, and 37s. 10d. one month. Business was done in Cumberland hematite at 47s. 7½d. each, and 47s. 10½d. one month. There has been nothing doing in Middlesbrough hematite, while the warrant market has been exceptionally quiet; the demand for pig iron for consumption at home is large, and this remark applies equally to ordinary iron and hematite, Scotch, and Cleveland pigs.

There are 41 furnaces producing ordinary, 37 hematite, and three basic iron, the total of 81 now in operation in Scotland comparing with 75 at this time last year. At Gartsherrie twelve furnaces are in blast, seven of them making hematite pigs, and ten at Eglinton, four of these being on hematite. Summerlee ordinary is being made by six furnaces. The highest class of ordinary Scotch pig is produced at Coltness, where it is being made by three furnaces, there being six making hematite at the same place.

In the course of the past week about 100 tons more iron was withdrawn from Glasgow stores than was sent in, and the total stock now amounted to 356,000 tons, compared with 283,000 at this time last year.

Prices of Scotch makers' pig iron are steady as follows:—Carnbroe, Monkland, and Govan, Nos. 1, 47s. 6d.; Nos. 3, 46s.; Clyde, No. 1, 50s.; No. 3, 47s.; Summerlee, Calder and Gartsherrie, No. 1, 50s. 6d.; No. 3, 48s.; Coltness, No. 1, 53s.; No. 3, 48s. 6d.; Glengarnock, at Ardrossan, No. 1, 50s.; No. 3, 46s.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington, at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts, at Leith, No. 1, 52s.; No. 3, 48s. 6d.; Carron, at Grangemouth, No. 1, 52s. 6d.; No. 3, 49s. 6d.

There is no improvement in the shipments of pig iron abroad, and the deliveries in the past week by coasting vessels appear to have been considerably less than the average of recent weeks. The total shipments amounted to only 4871 tons, compared with 8897 in the corresponding week of last year. To Holland was sent 790 tons, Italy 470, United States 15, India 373, Australia 125, France 55, Germany 357, Russia 255, Belgium 50, China and Japan 150, other countries 130, the coastwise shipments being 2101 tons, against 5991 in the same week of 1895.

Finished iron is quiet but steady, a fair business being reported, with comparatively little variation in price. The steel works are very busy, many of them working to their full capacity, with good orders in hand and in prospect.

The coal trade shows comparatively little alteration. In Fifeshire business is not quite so depressed as of late, and a rather better feeling is reported from Ayrshire, where consumers are said to be storing fuel on account of its present cheapness. The Glasgow market has been quiet. There is a good inquiry for the better classes of ell coal, but steam sells slowly. The supply of splint is very plentiful, and so is that of main. Quotations are nominally as follows:—Main coal, f.o.b. at Glasgow, No. 1, 6s. 3d. to 6s. 6d.; splint, 6s. 3d. to 6s. 6d.; ell, 6s. 3d. to 6s. 9d.; steam, 7s. 6d. per ton. The week's coal shipments show remarkably well, amounting, from the whole of the Scottish ports, to 189,614 tons, which compares with 152,063 tons in the preceding week and 29,917 tons in the corresponding week of last year. The dividend of John Watson, Limited, has been announced at 6s. per share on the ordinary shares, compared with 13s. in the preceding year, this large falling off being attributed to the exceptionally low prices ruling throughout the year.

At several works in the Glasgow district the operative engineers are on strike for an advance of wages, and their demands are understood to be greater than the employers feel warranted in conceding. It is believed that the dispute will be settled by compromise, without much further delay.

During April there was launched from the Clyde shipyards new tonnage amounting to 39,557 tons, compared with 28,567 tons in April, 1895. The output for the four months is 134,223 tons, compared with 81,434 in the same period of last year. The new orders booked in the course of the month are put as high as 7000 tons.

WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

A GOOD deal of animation in the steam coal trade prevails at Cardiff, and large cargoes have again been in evidence, notably two for 7000 tons and 6000 tons for Colombo. At Newport also the second largest steamer yet despatched from that port was cleared a few days ago. Swansea coal shipments for France and home ports have not been up to the average, but those for Russia and Canada have been exceptions, and prospects of the anthracite trade are good.

In house coal the time for any chance of recovery is regarded as gone, and prices are expected soon to rank even lower than at present. Steam coal prices are well maintained, and for best qualities nothing could be had in Cardiff last week under 10s., and a prominent quotation was 10s. 6d. Mid-week prices this week are as follows:—Best steam, 10s. to 10s. 6d.; market perceptibly stiffening. Best seconds in good request at 9s. 9d. to 10s.; drys, 8s. 9d. to 9s.; best Monmouthshire is selling much more freely at 8s. 3d. to 8s. 6d.; and seconds from 7s. 9d. to 8s. Best steam small varies from 4s. 3d. to 4s. 6d.; seconds, 4s.; and drys, 3s. 6d. to 3s. 9d.; best house coal, 9s. 9d. to 10s. 3d; No. 3, Rhondda, 9s. 6d. to 9s. 7½d.; brush, 7s. 9d. to 8s.; small, 6s. 3d. to 6s. 6d.; No. 2, Rhondda, 7s. to 7s. 6d.; through, 6s. to 6s. 3d.; small, 4s. to 4s. 3d. Coke shows no decline so far, though there is more quietness in the market. Cardiff prices are, furnace, 13s. to 15s.; foundry, 15s. 6d. to 16s. 9d.; and special foundry, 19s. to 19s. 6d. A large cargo, 1600 tons, left Cardiff this week for Valparaiso.

There has been a fair inquiry for patent fuel, Cardiff and Swansea, at last prices. From Swansea last week, amongst a few moderate cargoes dispatched was one of 1250 tons for Italy. Pitwood imports heavy; prices weak. I am pleased to chronicle a still larger make of tin bar in the district, supporting the view that things are a little better in tin-plate. Considerable consignments of tin bar have been sent West during the week, and I note that Cyfarthfa, in addition to long trains for the tin-plate districts, sent Midland and North quantities of crop ends of steel. A novel cargo was dispatched this week of 1020 tons steel billets, from Cardiff to Russia.

I have referred to the fact that Messrs. Crawshay Brothers, Cyfarthfa, are getting ready to figure again in the steel rail trade, and judging from preparations and the large addition of skilled hands made to the general manager's working staff, this branch will be an important one. The chief effort, of course, will be to win as high a repute for steel rails as the works have gained for steel bars, and, as those conversant with the manufacture know, this is only attained by keenest and most unremitting effort from the laboratory to the rolls. Taking a survey generally, there is more doing in the steel trade, rails being principally in demand. Stocks of pig and ore are lessening, and substantial cargoes are coming in daily. This week Dowlais had two, Cyfarthfa two, Blaenavon two, Société Commerciale one.

Swansea Exchange reports that the pig iron market has been weak, and the quotations mid-week were about 8d. lower than last week. Shipments, however, had been fairly maintained, the only exception being a slight falling off in Cumberland. Latest prices are: Glasgow warrants, 46s. 5d. cash; Middlesbrough No. 3, 37s. 9d.; hematite, 45s. 2½d.; Welsh bars, £5 10s. to £5 12s. 6d.; sheet iron, £6 15s. to £6 17s. 6d.; steel, £6 10s. to £6 12s. 6d.; Bessemer steel, tin-plate bars, £3 17s. 6d.; Siemens bars, best, £3 18s. Tin-plates remain at the old figures. Bessemer cokes, 9s. to 9s. 1½d.; Siemens, 9s. 1½d. to 9s. 3d.; ternes, 16s. 6d., 17s. 6d., to 22s. 6d.; best charcoal, 12s. 6d. to 12s. 9d.; wasters, 6d. to 1s. less, all delivered Prince of Wales's Dock, Swansea.

Other Swansea quotations are: Copper, Chili bars: £45 6s. 3d. to £45 8s. 9d. Block tin, £59 16s. 3d. to £59 17s. 6d. Lead, English, £11 5s. to £11 7s. 6d.; Spanish, £11 2s. 6d. to £11 5s.

Anthracite, best, 11s. to 11s. 6d.; second quality, 9s. to 10s.; ordinary large, 8s. 1d. to 8s. 9d. Steam coals, 9s. to 10s. best; seconds, 8s. 3d. to 9s.; No. 3 Rhondda, 9s. 6d. to 10s.; No. 2 Rhondda, 8s. 6d. to 9s. 6d.

It is expected that the dispute at Tumble will be ended satisfactorily. This will be hailed with pleasure at Llanelly. The latest report from the tin-plate works is that a few more mills have been started, and that shipments slightly exceed make. Stocks at Swansea amount to 151,535 boxes. Reports from America are to the effect that trade is much alike in both countries; only a slight improvement.

The death of Colonel North is announced. He will be remembered in the mining districts of South Wales as having acquired the Llynvi Collieries, Maesteg, Tondu, and Ogmore in 1889, but his connection in other respects was but a slight one, as he has only once since visited the district, when in token of his interest he made the workmen a present of £500.

The latest labour difficulty, with the exception of one or two collieries in South Wales, appears to have travelled north and broken out amongst the quarrymen of Penrhyn. The latest report is that 3000 men are out. The cause appears to be suspension of some for being absent without leave, and indignation of the rest, followed by abandonment of work wholesale.

The Barry Railway Company has succeeded at length in getting access to the Monmouthshire coal fields, and when the clauses of the Bill were taken on Tuesday, it also obtained running powers for passengers from its proposed new line to Caerphilly. The Committee decided, that if any alteration of the Caerphilly station became necessary it would be left to an arbitrator to say who should pay the cost.

The great struggle now pending is the Bute and Rhymney fusion. Mr. Pember's speech in opening took over three hours, and was very effective. From this it was gleaned that amalgamation scarcely conveys the objects of the promoters of the Bill. What they seek is power to purchase the Rhymney Railway. The opposition is strong. The Great Western, Midland, Taff Vale, and Barry oppose; but it has been pointed out, cogently, that three of these are out of court; the Great Western Company, Taff Vale, and Barry have their docks and railways. The object of the Bute Company is to have its railway, and be on level terms. Further, it has been shown that both the Taff Vale and the Barry have made strenuous efforts to get the Rhymney Railway, and this further weakens their opposition.

Mr. D. A. Thomas, M.P., made a statement in the House this week that the wages of over 100,000 colliers in South Wales have been reduced 50 per cent., and that Government should take immediate steps to assist them, similar to that suggested in the agricultural interest. I do not know what lines he will go upon. Doubtless it will be contended in opposition that many cases of depression have been due to the action of the men themselves, and the extreme difficulty found by coalowners in bringing about settlements by arbitration. Late cases have been Plymouth and the Mardy. And it is quite possible that it will be urged that the distress in agricultural districts has not been brought about by similar causes to those acting in the mineral districts. Wales, unfortunately, has on several occasions brought about bad trade by labour agitation, from which the counties have been free.

NOTES FROM GERMANY.

(*From our own Correspondent.*)

VERY satisfactory accounts continue to be given of the continental iron trade, generally, all descriptions of iron and steel remaining in good demand. Changes of importance have not taken place since last week; inquiries are plentiful, and prices, on the whole, more firm than before. The business done on foreign account may also be considered pretty favourable, though heavy orders are still scarce, but makers are content with the steady, if somewhat limited, demand that is now coming forward, and hope for a more animated trade in the next quarter.

The iron business in Silesia remains in a most satisfactory state. Both raw and finished iron makers are very well off for orders, and quotations are, as a rule, extremely firm. Export has been specially brisk upon the week, and present prices are fairly remunerative.

The situation of the iron market in Austria-Hungary does not present any novel feature. A good employment is maintained at the various establishments, and makers report themselves pretty well satisfied with the present state of things, the more so because prices are showing a decidedly upward tendency, and have, in a few instances, been quite favourable compared to previous months. There is, of course, not much gained at present, but an advance in the quotations for several articles of finished iron will most likely take place in June. The works that are engaged in producing railway material have received further orders within the course of last week, one being for 450 and another for 400 goods wagons.

The French iron trade has been progressing favourably since las week; the strong tone of the market is illustrated by the fact that basis price for girders has been raised to 155f. p.t. free Paris; bars are not obtainable below 155f. p.t., while plates stand on 165f. p.t.

A most animated business continues to be transacted on the Belgian iron market. General confidence in the future of the iron trade has further increased, partly on account of the favourable results of last week's tenderings for scrap iron and steel. For old iron rails offers ranged between 82f., 86f., and 88·50f. p.t., while last year only 65f. to 70f. p.t. were obtainable. Old steel rails are to be had at 66f. p.t., last year 55f. p.t. were asked. One Government order for angles, No. 3, has been booked at 164·80f. p.t.; a short time ago prices were standing on 127·50f. p.t. Plates, which had until now not joined in the general upward movement, are also beginning to improve, and an advance of 2·50f. p.t., had last week been agreed upon for home consumption, No. 2 now fetching 155f. to 157f. p.t. Export prices are naturally a trifle less firm, but may also be considered more remunerative than before.

Some heavy rail orders have recently been booked, chiefly for East India. There is likewise a fair amount of fresh work coming in at the construction shops, and the hitherto somewhat moderate employment has changed into brisk activity. Pig iron continues scarce, but there will be an increase in production before long, two additional blast furnaces being blown in at Hourpes and Athus.

On the Rhenish-Westphalian iron market increasing activity is the general report. In the pig iron trade new contracts are coming in freely, both on home and foreign account, and in the finished iron department makers are also booking a larger weight of orders than they have been doing for many months. Prices have advanced in rather a marked way, and are now generally considered as remunerative. Here and there orders for the fourth quarter have already been placed, a fact which cannot fail to have a stiffening influence on quotations; and as the demand for all sorts of iron for structural and engineering purposes is likely to increase during the next months, prospects in the iron trade may justly be considered as highly satisfactory. Stocks in the hands of both makers and dealers are but small, generally. In the hardware and cutlery trade there has also been a much more lively occupation reported lately, and the business in tools and agricultural implements naturally shows a certain animation, and satisfactory prices are, as a rule, obtained. The only branch of the iron industry which continues weak and altogether neglected is the tube business, which does not show the slightest inclination to improve. The wagon shops continue to be reported in healthy and remunerative employment.

The production of pig iron in Germany was for March, 1896, 551,157 t., of which 159,002 t. were forge pig and spiegeleisen, 46,013 t. Bessemer, 281,465 t. basic, and 64,677 t. foundry pig. Output in March, 1895, was 481,144 t., that for February of present year amounting to 496,170 t. From the 1st of January to 31st of March, 1896, no less than 1,560,355 t. were produced, against 1,405,423 t. for the same period the year before.

Regarding German foreign trade in all sorts of raw material and finished articles, in corn, cattle, coal, dyeing materials and drugs, it has been officially stated that imports amounted to 2,561,342 t., against 1,975 981 t. in March, 1895, plus amounting to 585,361 t.; export for March of present year was 2,031,483 t., against 1,843,007 t. in March, 1895, plus being 188,476 t. Value of import was, for the first quarter of 1896, M. 1,097,423,000, against M. 965,159,000 in the previous year, which shows an increase of M. 132,264,000. Value of export for the same period was M. 861,445,000, against M. 758,895,000 in the year before, which shows an increase of no less than M. 102,550,000.

AMERICAN NOTES.

(*From our own Correspondent.*)

NEW YORK, April 30th.

FOR three weeks commercial activity has been less pronounced. The banks have been accumulating money, and are more willing to lend than borrowers are to borrow. Railroad reorganisation is progressing finely. A vast amount of dead losses will be wiped out, and unremunerative securities will soon cease to constitute a portion of the stock-in-trade of Stock Exchanges. Railroads are not making that improvement in earnings that was hoped for. The Government supply of free gold is now 126,000,000 dols. New York banks have 487,000,000 dols. deposits. Large exports of silver continue. The iron trade is rather inactive. The billet pool has not as yet succeeded in forcing consumers to pay the higher prices, except for small lots. Steel makers are hesitating, and there is some vague uncertainty as to the position of coke and ore in July, though both these interests claim there is no possibility of a break in prices. An unusual amount of work is projected in all channels. In railroad work, the projected mileage is between 30,000 and 40,000 miles, but very little work is under construction. Much of this mileage is needed and would earn dividends, but the capital cannot be had to enter on construction. There are hundreds of big enterprises, and it might be said without exaggeration, thousands of little enterprises all ready for prosecution, but influences check action—just what, it is not easy to intelligently define. The two great political conventions are the absorbing topic of the hour; there is great uncertainty as to the outcome. Municipal improvements, such as for light, water, street railways, drainage and other matters, will absorb a larger sum of money than in any two former years. Electric roads by the hundred will be built before the close of the year. Machine shops and large engine shops are gathering in a great deal of work.

THE GLASGOW LOCOMOTIVE TRADE.—In the locomotive trade of the Glasgow district, which is certainly the headquarters of the branch of the mechanical engineering industries, so far as this country is concerned, there is a very decided "boom" just now, more especially in the works of the private firms. Report has it that Messrs. Neilson and Co., of Hyde Park Locomotive Works, Springburn, have at least 170 engines on order or in course of construction, which means full and continuous employment for a large army of skilled workmen for upwards of a twelvemonth, even though no more orders should be booked during that time. But that is not actually the "record" of work at Messrs. Neilson's establishment, for at the beginning of the year 1885 there were upwards of 200 locomotives on the order books. With fairly good prices for the engines turned out, it was but natural to expect that the late head of the concern, Mr. James Reid, ex-Lord Dean of Guild of the City of Glasgow, should have been a wealthy man at his death.

8539. Lifts, S. Skerritt and J. Hibbert, Sheffield.
8540. Measure, J. W. Hannah, North Shields.
8541. Electric Lamps, W. Woodhead, Halifax.
8542. Centrifugal Machines, J. Laidlaw and J. W. Macfarlane, Glasgow.
8543. Spindles, R. Brodie, Glasgow.
8544. Chimney Cans, T. Daly, Glasgow.
8545. Smoke Cowl with Steam Injector, W. Boyes, jun., Birmingham.
8546. Cycle Lamps, W. Hunter and H. Hunter, Birmingham.
8547. Maximum Thermometer, A. Luraschi, London.
8548. Boring and Planing Machine, C. R. Iorns, Altrincham.
8549. Construction of Ladders, W. Hayward, sen., Wolverhampton.
8550. Construction of Hurdles, W. Hayward, sen., Wolverhampton.
8551. Bicycle and Tricycle Appliances, C. M. P. H. Triscott, London.
8552. Reversible Shirt Fronts, J. Reynolds, jun., Nottingham.
8553. Ships' Anchors, J. Evans and A. Evans, Liverpool.
8554 Steam and Hydraulic Vacuum Gauge, J. Jackson, Wallingford.
8555. Internal Combustion Motor Engines, G. McGhee, Glasgow.
8556. Preventing Fraud in Bottling Liquors, C. E. Lefaux, Swansea.
8557. Preserving Flesh, Fruit, Fish, &c., H. Winks, Parkstone.
8558. Using Mine Dust of Iron from Kilns, G. Fisher, Shotts, Lanark.
8559. Advertising Device, R. H. H. Baird, Glasgow.
8560. Aerial Toy, J. E. Livsey, London.
8561. Drain or Pipe Stoppers, A. W. Bullen, Hampton Wick.
8562. Writing Apparatus for the Blind, H. C. A. Krüger, Birmingham.
8563. Window Fittings, J. Lumsden, London.
8564. Flower Pots, J. Black.—(*J. B. and E. Chéron, France.*)
8565. Folding Chair, G. D. Wilhelm, London.
8566. Preparing Jellies in Tablet Form, J. H. Payne, London.
8567. Latch Locks, E. P. O'Kelly, London.
8568. Racquet and Lawn Tennis Bats, W. Cutler, London.
8569. Making Electric Contacts by the Passing of Railway Trains, E. Tyer, London.
8570. Umbrellas, S. A. Parkes, London.
8571. Steering Lock for Cycles, R. Woodhouse, London.
8572. Fastening for Lawn Tennis Posts, &c., R. Bell, London.
8573. Bicycle Support, G. Spencer, London.
8574. Cinder Sifter and Ash Collector, H. Paine, London.
8575. Soap for Chemical Cleaning, &c., O. Schöning, London.
8576. Checking the Consumption of Stamps, J. Hart, London.
8577. Combined Washstand and Dressing Table, C. F. Turner, London.
8578. Grip for Fencing Wire, F. Kirby, Norwich.
8579. Tires for Cycles, F. I. Gibbs and W. Wright, Birmingham.
8580. A New Preparation of Tea, H. Boisselier, Enfield.
8581. Latch Keys, E. Ingram, Hereford.
8582. Tanning Extracts, H. H. Lake.—(*The Firm of Leptit, Dollfus, and Gansser, Italy.*)
8583. A New Metal Box, A. J. Spry, London.
8584. Pedal Action for Cycles, J. and H. M. Copeland, New Zealand.
8585. Dress Skirts, &c., F. Thenn and G. Souder, London.
8586. Rotation of Wheels, A. E. Woodhouse and R. B. Bristed, London.
8587. Swivels for Chains, Cuff Links, &c., H. Edmonds, London.
8588. Cultivation of Orchids, &c., A. G. C. Stollery, London.
8589. Elastic Tires for Cycles, J. Smyth, London.
8590. Pneumatic Tires, E. Hale, Liverpool.
8591. Apparatus for Turning Articles, J. Ruscoe, Manchester.
8592. Tires for Road Vehicles, F. W. R. Scott, Liverpool.
8593. Devices for Opening Oysters, J. B. Gastaldi, Liverpool.
8594. Carrier Frame for Pot Plants, G. H. Shoults, London.
8595. Fusible Metal or Alloy, T. Smith, London.
8596. Speed Regulating Mechanism, A. Paget, London.
8597. Advertising Device, W. H. Bradley, London.
8598. Stroke Counting Apparatus, J. U. Meier, London.
8599. Pill Machine, W. L. Wise.—(*P. J. Noyes, United States.*)
8600. Sewing Machines, H. H. Lake.—(*J. W. Smith, United States.*)
8601. Hydraulic Engineering, P. A. Waller, London.
8602. Preventing Deposit in Kettles, W. L. Dash, London.
8603. Type Line Justifiers, G. W. Sherer, London.
8604. High-pressure Valves, &c., E. J. Preston, London.
8605. Cycles, J. E. Bousfield.—(*E. Worms and J. P. Bonicard, France.*)
8606. Steam Engines, P. Giffard, London.
8607. Straining and Splicing Fencing Wire, J. Dalziel, London.
8608. Lookouts for Use on Board Ship, R. Türr, London.
8609. Cuffs, C. C. Clark and H. C. Barber, London.

24th April, 1896.

8610. Wheel for Vehicles, R. J. Churchill, Derbyshire.
8611. Pilot Light, W. Wright and F. J. P. Reed, Plymouth.
8612. Operating Levers or Cocks, C. E. G. Simons, Merthyr Tydfil.
8613. Pre-payment Apparatus for Meters, J. Brightman, Rotherham.
86'4. Water-closet Traps and Moulds, P. J. Davies, London.
8615. Metallic Eyes of the Handles of Trees of Spades, J. Mills, Lye, near Stourbridge.
8616. Napkin Rings for Table Purposes, W. White, London.
8617. Driving Belts, W. E. Sharples, Manchester.
8618. Side Scuttles, G. T. Temple, H. B. and J. S. Watson, Newcastle-on-Tyne.
8619. Beetle Traps, H. Whittaker, Manchester.
8620. Metal Edged Cardboard Boxes, M. Heinemann, Birmingham.
8621. Foul Linen Shoots, D. K. Tullis, Glasgow.
8622. Waste or Discharge Valves, T. Law, Glasgow.
8623. Mud Guards for Wheels, J. G. A. Kitchen, Manchester.
8624. Combined Chair and Musical Box, E. Schacht, Glasgow.
8625. Ships' Side Lights, R. Brown, Newcastle-on-Tyne.
8626. Cycles, L. and W. Hanson, and J. Sanders, Halifax.
8627. Bearings for Forge Trains, C. Billington, sen., and J. Newton, Longport.
8628. Chain Wheels used with Cycles, H. J. Heinze, London.
8629. Securing Handles to Hammers, J. R. Cooper, Birmingham.
8630. Magnetic Motors, J. Chandler, Liverpool.
8631. Driving Gear for Cycles, J. B. King, Stonehouse.
8632. Wind Musical Instruments, J. A. Kappey, Chatham.
8633. Cycle Mud Guards, H. J. Lingwood, Stafford.
8634. Manufacture of Chlorine, S. A. Sadler and R. H. Wilson, Middlesbrough.
8635. Winders, T. Holcroft and Sons, and A. H. Mould, Wolverhampton.
8636. Curling the Hair, J. Taylor and W. A. Lloyd-Davies, Wolverhampton.
8637. Folding Chair, W. Blackwell, S. Ball, and J. Mitchell, Birmingham.
8638. Screw-cutting Lathes, F. W. Walker, Bradford.
8639. Furnaces, R. A. Lewis, Lemington-on-Tyne.
8640. Broadcast Manure Distributor, R. and W. Wallace, Ayr.
8641. Chain Adjuster for Cycles, G. Wright, Nottingham.
8642. Composition Roller, G. B. Ford, Burslem.
8643. Strain Reducer for Draught Animals, F. J. Wilkinson, London.
8644. Coin-freed Mechanism, J. Tourtel, London.
8645. Pneumatic Tires, J. B. Price and E. T. Whitelow, Manchester.
8646. Memorandum or Scribbling Desk, W. Gun, Manchester.
8647. Induction Electrical Machines, F. Tudsbury, Sheffield.
8648. Tube Cleaner, A. Willis, London.
8649. Seal and Fastener, J. G. and R. T. Glover, London.
8650. Tea Baskets, A. Clark, London.
8651. Mechanical Ventilating Apparatus, J. L. Purdy, London.
8652. Oxalic Acid, C. F. Wülfing, London.
8653. Closets, F. W. Golby.—(*F. Dumay and E. Sauvegarde, Belgium.*)
8654. Auto-motor Carriage, W. March, London.
8655. Brake Apparatus, A. A. Tyler, W. March, and H. Penn, London.
8656. Conveying Cycles in Railway Vans, C. Casman, London.
8657. Cleaning Chaff and the like, S. Trewin, Watford.
8658. Brakes, E. E. Shearburn, London.
8659. Paste Carrying Plates, F. W. Schneider, London.
8660. Cells for Electric Accumulators, F. W. Schneider, London.
8661. Ornamenting Celluloid Ferrules, T. E. Weaver, Wolverhampton.
8662. Bottle Stands, M. H. H. King, London.
8663. Producing Colour Photographs, W. White, London.
8664. Cutting and Bagging Chaff, G. Bowmar, London.
8665. Construction of Vessels, G. Hough, London.
8666. Battery Electrodes, The Battery and Motor Company, Ld., and H. T. Barnett, London.
8667. Cards for Holding Buttons, J. Proskauer, London.
8668. Tires for Cycles, S. G. Coulson, London.
8669. Appliances for Sharpening Pencils, W. Pair, London.
8670. Means for Stretching Trousers, C. White, London.
8671. Covering or Wrap for the Neck, G. Szuhanek, London.
8672. Substitutes for Celluloid, S. W. Wilkinson and The Grove Company, Ltd., London.
8673. Ships' Propellers, W. P. Thompson.—(*H. Brinkmann, Germany.*)
8674. Reversing Gear, W. P. Thompson.—(*H. Brinkmann, Germany.*)
8675. Appliance for Velocipedes, F. A. Skidmore, Birmingham.
8676. Pneumatic Tires, R. Reid, London.
8677. Non-refillable Bottles, G. W. Johnson, London.
8678. Lubricating Cycles, S. Chandler, jun., and J. Chandler, London.
8679. Gas Combustion Chambers, J. Hartmann, London.
8680. Support or Stays for Cycles, A. F. Aberg, London.
8681. Cranes, S. W. A. Noble and C. H. Murray, London.
8682. Electrical Firing Apparatus, C. A. McEvoy, London.
8683. Driving Gear for Velocipedes, A. Hollands, London.
8684. Telephones, F. L. Muirhead, London.
8685. Wheels and Tires for Cycles, M. Lachman, London.
8686. Manufacturing Pipe-shaped Cigars, S. Veit, London.
8687. Apparatus for Propelling Boats, H. Barcroft, London.
8688. Chair Sleepers for Railways, A. R. Jones, London.
8689. Making Holes in Brush Backs, C. E. Flemming, London.
8690. Metallic Alloys, S. O. Cowper-Coles and S. Learoyd, London.
8691. Ores, A. J. Boult.—(*Salisbury-Jones, Bidwell, and Co., South Africa.*)
8692. Corks for Closing Bottles, W. R. Maud, London.
8693. Railway Signalling Apparatus, A. J. Boult.—(*A. Becker, Belgium.*)
8694. Folding Binocular Glasses, S. H. Cobb, London.
8695. Electrodes for Accumulators, W. Majert, London.
8696. Pneumatic Tires for Cycles, A. Pulbrook, London.
8697. Steam Turbine Blades, The Hon. C. A. Parsons, London.
8698. Steam Turbine Blades, The Hon. C. A. Parsons, London.
8699. Improved Whist Marker, A. G. C. Stollery, London.
8700. Supports for Blotters, C. E. Locke, London.
8701. Venetian Blinds, J. Manttan, London.
8702. Lamp Shades, W. R. Hitchcock, London.
8703. Union Nuts, E. Martin, London.
8704. Acetylene Gas, F. L. and E. T. Perken and A. Rayment, London.
8705. Loom Heald Shafts, G. G. M. Hardingham.—(*Felten and Guilleaume, Germany.*)
8706. Furniture Polish, W. I. Grylls, London.
8707. Charging Valve for Furnaces, J. Hartmann, London.
8708. Combined Bed and Sofa or Couch, G. Silberblatt, London.
8709. Forgings, F. Radcliffe, London.
8710. Matrix Making Machines, E. Latham, London.

25th April, 1896.

8711. Radioscope and Heat Motor, A. R. Bennett, London.
8712. Disinfecting and Cleansing Mixture, W. Hanlon, Innishannon.
8713. Elastic Tires, J. Pickles, Bradford.
8714. Duplicate Saddle for Velocipedes, T. H. Wem, Lichfield.
8715. Pumps for Tires, T. Humpage and H. I. Jaques, Bristol.
8716. Pneumatic Tires for Velocipedes, W. F. Taylor, Croydon.
8717. Spades, A. and J. Perks and W. C. Salmon, Wolverhampton.
8718. Nathaline, E. Morrice, London.
8719. Ball Castors, A. Cubitt and N. A. Thompson, Ipswich.
8720. Driving Gear, A. J. Lehmann, J. Hillyard, and G. T. Haigh, Liverpool.
8721. Weaving, J. G. Barnes, Manchester.
8722. Blind Tape Fastener, A. Cameron and H. E. Skinner, Sunderland.
8723. Tires, S. Roberts, Halifax.
8724. Tables for Surgical Purposes, J. W. Ward, Halifax.
8725. Tools for Marking Timber, J. Brawn, Birmingham.
8726. Geographical Diagram Charts, F. Cox, Liverpool.
8727. Kettles for Boiling Water, &c., H. Blandy, Nottingham.
8728. Moulding the Soles of Boots, W. H. Dorman, Stafford.
8729. Teaching Shaping, Sewing, &c., R. Greenhalgh, Manchester.
8730. Securing Picking Straps to Pickers, J. Whittaker, Manchester.
8731. Cans for Perishable Goods, J. W. Brooke, London.
8732. Cotton Yarn, L. W. Roberts and J. C. Wood, Manchester.
8733. Cycles, W. H. Dawson, Manchester.
8734. Vent Pegs, J. Magee, Glasgow.
8735. Transplanting Instruments, W. W. Richards, Birmingham.
8736. Method of Heating Liquids, L. Classey, Ireland.
8737. Fastenings for Drawers, &c., R. McTaggart, Glasgow.
8738. Potato Lifters, J Chalmers and W. Addie, Glasgow.
8739. Cycles, J. Cockburn, W. H. Luther, and J. Millar, Glasgow.
8740. Cook's Adjustable Set-square, W. V. Cook, Ipswich.
8741. Cycle Saddles, W. Wingate, London.
8742. Folding Bed Screen, A. Lange and W. Fleher, London.
8743. Speaking Tube Receivers, H. A. Cutmore, London.
8744. Cooking Stoves, F. J. Duggan and C. Isaac, London.
8745. Cotton Reels, E. A. Houchin, London.
8746. Sash Fasteners, A. Line, London.
8747. Cycles, C. H. Maleham, Sheffield.
8748. Ink Ducts, F. C. Taylor and J. Cooke, London.
8749. Pneumatic Tires for Road Wheels, B. Ljungstrom, London.
8750. Nut Locking Device, W. P. Thompson.—(*E. Meller, Austria.*)
8751. Aerial Machines, H. S. Booth, Manchester.
8752. Composition for Roads, Paths, &c., G. H. Sharpe, London.
8753. Vaporiser for Oil Engines, T. Myers, London.
8754. Subduing Noxious Odours of Oils, T. Myers, London.
8755. Silencing the Exhaust from Gas Engines, T. Myers, London.
8756. Manufacture of Rims of Cycles Wheels, H. Hill, London.
8757. Compressed Gas Cylinders, J. Airs, London.
8758. Steering Wheels of Ships, A. W. F. Bennik, London.
8759. Chain Swivels, T. Keetman, London.
8760. Footballs, W. Dalgleish and H. A. Cook, London.
8761. Mechanical Toy, W. Bottrill, London.
8762. Pocket Case for the use of Cyclists, J. W. Tysoe, London.
8763. Reversible Water Motor, A. T. Thompson, London.
8764. Self-propelling Vehicles, A. R. Sennett, London.
8765. Cure of Gout, W. J. Baker and F. W. Roloff, London.
8766. Ladies' Garments for Cycling, F. H. Müller, London.
8767. Pipes for Smoking Tobacco, A. H. B. Sharpe, London.
8768. Hardening Iron and Steel, J. A. Mays, London.
8769. Piston Slides, C. D. Abel.—(*Dingler'sche Machinen Fabrik, Germany.*)
8770. Manufacture of Alkyl Glycolic Acid, H. Imray.—(*Basle Chemical Works Bindschedler, Switzerland.*)
8771. Apparatus for Collecting Refuse, A. Hartwich, London.
8772. Gun Cleaning Implements, &c., J. Hinne, London.
8773. Producing High-speed Gaseous Currents, R. Haddan.—(*E. Chesmay, France.*)
8774. Boiler Furnaces, J. Brown and Co., and J. Nodder, London.
8775. Boiler Furnaces, J. Brown and Co., and J. Nodder, London.
8776. Incandescent Gas Burners, E. W. Hampton and J. R. Wright, London.
8777. Pneumatic Tires, S. Chandler, jun., and J. and J. C. Chandler, London.
8778. Tipcats, C. Crouch, London.
8779. Tires for Wheels of Velocipedes, J. M. Herschell, London.
8780. Boxes for Packing Biscuits, F. Vinten, London.
8781. Reduction of Composite Lead, C. T. J. Vautin, London.
8782. Refrigerating Apparatus, W. Hampson, London.
8783. Auto-cars for Road Traffic, W. S. Simpson, London.
8784. Preventing Vibration of Cycles, W. S. Simpson, London.
8785. Manufacture of Arsenic, W. Bevan, London.
8786. Device for Use with Umbrellas, H. N. Powell, London.
8787. Exhaust Steam Injectors, R. G. Brooke, London.
8788. Driving Gear, W. S. Smith, London.
8789. Appliance for Modulating Tones, F. J. Smith, London.
8790. Photographic Apparatus, T. d'Oksza and G. Bourrelly, London.
8791. Centrifugal Separators, H. H. Lake.—(*T. T. A Hansen, Denmark.*)
8792. Back Linings for Books, G. B. Soelberg, London.

27th April, 1896.

8793. Gas Cooker, W. P. Thompson.—(*G. Horn, Germany.*)
8794. Rail Cleaner for Tramways, D. E. Hipwell, London.
8795. Tires, D. E. Hipwell, London.
8796. Pneumatic Tires, J. B. Scammell, London.
8797. Dead-beat Sectioner, H. Creegan, Chester.
8798. Bicycle Standing Gear, B. Phelan, London.
8799. Clips for Cordage, R. R. Macnee, Glasgow.
8800. Hair Curlers, G. H. Twigg, Birmingham.
8801. Fastening Metallic Cork Stoppers, A. Millin, Belfast.
8802. Switchboards, C. Shore and C. Heap, Rochdale.
8803. Cutting V-pieces from Paper, &c., J. Bennett, Bristol.
8804. Frames for Photographs, &c., R. B. Miller, Dundee.
8805. Cocks or Taps, C. H. J. Rudd, Newcastle-on-Tyne.
8806. Heating Domestic Water Supply, W. Wilson, Leigh.
8807. Gas Lighting, A. Köhler, Hamburg.
8808. Picnic Knife and Fork, E. Lapp, Hamburg.
8809. Operating Window Blind Rollers, H. Lomax and Lomax, Limited, Halifax.
8810. Dynamo-electric Machines, J. Edmondson, Halifax.
8811. A Force Accumulating Motor, E. Walker, Yorks.
8812. Gas Lighting, H. G. Frost, Deal.
8813. Gas and Oil Engines, H. N. Bickerton, Manchester.
8814. Rolling Continuous Bands of Metal, H. and H. W. Guthrie, Manchester.
8815. Electric Light Switches, G. Davis, London.
8816. Rotary Engines, R. Studdert, Manchester.
8817. Automatic Locking Apparatus for Doors, H J. Hayes, Norwich.
8818. Detachable Covers for Pneumatic Tires, J. Newhouse, Lancashire.
8819. Railway Pilotman's Substitute Apparatus, J. W. Mitcherd, Merioneth.
8820. Advertising, A. E. Taylor, Manchester.
8821. Ticket Holder for Railway Wagons, E. Platt, Manchester.
8822. Station Indicator for Passenger Trains, W. Baxendale and E. Platt, Manchester.
8823. Pans of Water-closets, J. E. and W. H. Place, Manchester.
8824. Spindles for Locks and Latches, W. H. Baynes, London.
8825. Letter-boxes, &c., S. Hill and R. Hodges, London.
8826. Cyanides, J. A. Wanklyn and W. J. Cooper, Surrey.
8827. Centrifugal Governors, J. N. and W. Paxman and J. C. Peache, London.
8828. Affixing Shafts to Dog-carts, G. and J. Hayward, London.
8829. Motor, R. Quigly, London.
8830. Locking Cycles, A. H. Dickinson and H. J. Fisher, London.
8831. Manufacture of Coffee, H. Boisseleir, Enfield.
8832. Turbines, H. A. House, sen., and R. R. Symon, London.
8833. Anchors, H. A. House, sen., and R. R. Symon, London.
8834. Tea-leaf Rolling Machines, S. C. Davidson, London.
88 5. Tubulous Steam Generators, B. H. Thwaite, London.
8836. Cisterns, C. T. Lee, London.
8837. Colander, E. C. Johnston, London.
8838. Pneumatic Tires, G. F. Redfern.—(*R. Reid, Australia.*)
8839. Apparatus for Exhibiting Play-bills, L. C. Cropper, London.
8840. Tires for Wheels of Bicycles, W. Cutler, London.
8841. Device for Burning Tobacco, J. Conning, London.
8842. Tongs, W. Brittain, London.
8843. Cycle and other Lamps, W. B. L. G. Toler, London.
8844. Rafts for Use in Water Velocipedes, J. T. Harris, London.
8845. Head for Otter Trawl Net, W. Walker, London.
8846. Dynamo-electric Machine, H. Sandwith, London.
8847. New Steering Lock for Cycles, A. Gower, London
8848. Pneumatic Tires, S. B. Archdeacon and B. McA. Bannatyne, Liverpool.
8849. Drive Chain for Cycles, A. Appleby, Birmingham.
8850. Device for Wire-drawing Machines, H. Pieper, London.
8851. Pumps, Air Compressors, &c., J. G. Walker, London.
8852. Manipulating Ventilators, &c., J. G. Walker, London.
8853. Improved Generator of Electricity, H. Arzt, London.
8854. Screw Nails, E. Edwards.—(*J. Schumann, Germany.*)
8855. Propulsion of Vessels, J. F. Green, London.
8856. Cushion for Billiard Tables, W. Buttery, London.
8857. Colouring Matters, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
8858. Working Single Lines of Railway, E. Tyer, London.
8859. Apparatus for Propelling Boats, H. Barcroft, London.
8860. Discharging Colour, O. Imray.—(*The Farbwerke vormals Meister, Lucius, and Brüning, Germany.*)
8861. Purifying Acetylene, O. Imray.—(*E. Rousseau, Belgium.*)
8862. Substitution for Bolt, M. D. Martindale, London.
8863. Eaves' Gutters, W. R. Pryke and W. Palmer, London.
8864. Finger Rest for Penholders, J. T. Ahrens, London.
8865. Colour Photographs, B. J. Edwards, London.
8866. Musical Instruments, N. Calace and R. Calace, London.
8867. Thermometers, G. H. Zeal, London.
8868. Device for Speedy Locomotion, H. S. Halford, London.
8869. Pneumatic Tires for Cycles, H. S. Halford, London.
8870. Chimney for Gas Incandescent Light, M. Raphael, London.
8871. Shock Covers, H. Walker, London.
8872. Machines for Making Casks, &c., G. Rettig, London.

8873. Condensing Steam Engines, K. Lundkvist, London.
8874. Ratchet Drills, V. Kuchar, London.
8875. Brakes for Cycles, Vehicles, &c., J. McRae, London.

28th April, 1896.

8876. Manufacturing Boot Welts, A. C. Spencer, London.
8877. Machines for Printing Colours, V. Turati, London.
8878. Cloth Caps, J. G. Hudson, London.
8879. Hames of Horse Collars, H. T. Simpson, London.
8880. Pneumatic Tubes for Cycles, T. H. Williams, London.
8881. Cycle Tire, J. C. Kenwood, St. Leonard's-on-Sea.
8882. Non-slipping Floor Covering, A. Tracy, Retford.
8883. Reels, C. A. Rickards and A. Richmond, Bradford.
8884. Detecting Punctures in Tires, H. Branter, Bradford.
8885. Timing-in Clocks for Pigeon Races, J. Pitt, Bradford.
8886. Advertising, W. C. Lister, Wolverhampton.
8887. Tiles, Slabs, Wallings, &c., J. S. Rigby, Liverpool.
8888. Apparatus for Obtaining Cyanides, J. B. Readman, Glasgow.
8889. Engines, R. G. Morton, Glasgow.
8890. Electricity and Water Supply, T. Meacock, Birmingham.
8891. Joints of Cornice Poles, W. A. Bibb, Birmingham.
8892. Securing Pneumatic Tires to Rims, A. S. Cartwright, Birmingham.
8893. Regulating Steam Engines, D. Robertshaw, Halifax.
8894. Attachment of Filigree Metal Work, M. Watts, Birmingham.
8895. Bandages, M. Arnold. Manchester.
8896. Pneumatic Tires, J. Mosely and B. Bluudstone, Manchester.
8897. Tires for Vehicle Wheels, R. Hunt, Liverpool.
8898. Catching Plates, H. J. Ridley and D. Davies, Carmarthen.
8899. Round Buddle, G. Robson, Merioneth.
8900. Apparatus for Propelling Bicycles, H. A. Poole, Rochdale.
8901. Magnetising Boxes, J. Y. Johnson.—(*Electric Hardware Manufacturing Company, United States.*)
8902. Leaf Turner for Music, &c., J. Beauchamp, London.
8903. Gear Case, J. Fielding, Manchester.
8904. Valves for Gas and Oil Motors, D. Mottershead, Manchester.
8905. Saddles, H. D. Pearsall, London.
8906. Generating Electricity, L. B. Atkinson and F. G. Treharne, Penarth.
8907. Alloy of Iron, T. Twynam, Egham.
8908. Wheels, A. H. Gorsuch, J. Crowther, and G. H. Richmond, Manchester.
8909. Dress Retainer for Lady Cyclists, E. Overend, Dublin.
8910. Valves, J. Scowcroft and E. Nightingale, Manchester.
8911. Steam Traps, R. Nightingale and J. Scowcroft, Manchester.
8912. Cycle Wheels, M. Conlan and W. Moores, Manchester.
8913. Pneumatic Tires, J. Adair, Waterford.
8914. Boxes for Holding Millinery, J. Bennett, Bristol.
8915. Combined Clip and Invoice File, S. Learoyd, Huddersfield.
8916. Driving Gear for Cycles, A. E. Cotton, Nottingham.
8917. Sleeve Grip, G. Sherlock, London.
8918. Explosion Engines, D. Young.—(*L. S. Gardner, United States.*)
8919. Fixing Detonators, D. Slade and C. Tayler, Liverpool.
8920. Fare Registers, F. C. Boyd and C. E. Gierding, London.
8921. Cycles, C. A. Jensen.—(*Bolte Cycle Manufacturing Co., United States.*)
8922. Cycle Lamps, J. G. Halford, London.
8923. Cigar Holder, F. L. Schmitz.—(*F. H. Schmitz, Austria.*)
8924. Adjustable Cycle Support, M. Goodman, London.
8925. Frames for Doubling Yarns of Cotton, F. Wood, London.
8926. Brake Mechanism, G. Conaty and J. F. Mason, Manchester.
8927. Advertising Apparatus, F. Prestwich, Manchester.
8928. A New Method of Dispersing Fog, F. Frey, London.
8929. Pneumatic Tires for Cycles, J. C. Lighthouse, London.
8930. Merry-go-rounds or Roundabouts, W. Reynolds, London.
8931. Pulp Strainers, J. White and A. W. Allan, Glasgow.
8932. Hasp and Staple, W. F. Woolfenden and F. H. Greaves, Liverpool.
8933. Stop Runaway Check, C. Hillen and D. Smith, Southport.
8934. Mechanical Toy, R. H. Bishop and A. W. Pocock, London.
8935. Mantles, &c., Heated by Gas, W. B. Smith, London.
8936. Rag Dolls, J. R. Mally, London.
8937. Faces of Dolls, J. R. Mally, London.
8938. Pneumatic Tires, J. T. Trench, London.
8939. Pneumatic Tires, J. T. Trench, London.
8940. Masks, G. Lams, London.
8941. Appliance for Riding Cycles, W. Wingate, London.
8942. Propelling Apparatus for Ships, R. A. Smith, London.
8943. Metal Caps, R. Williams, Chiswick.
8944. Umbrellas, R. P. Hull, H. K. Beck, and H. M. Hawley, London.
8945. Printing on Envelopes, &c., J. S. Duncan, London.
8946. Purifying Iron, H. H. Lake.—(*Hawkins Steel Company, United States.*)
8947. Making Gear Teeth, H. G. Warren, London.
8948. Signalling Apparatus, H. H. Lake.—(*G. E. Painter, United States.*)
8949. Steam Boilers, D. and F. D. Almy, London.
8950. Boots, H. H. Lake.—(*E. B. Seaver, United States.*)
8951. Steam Generators, D. M. Thompson, London.
8952. Bottling Gaseous Liquors, J. Fletcher and Ryder and Co., London.
8953. Transportable Scaffolding, &c., P. Schulz, London.
8954. Holders for Stretching Machines, A. A. Whitley, London.
8955. Motive Power Engines, G. Gascoine, London.
8956. Grain Elevators, E. Blanchard, London.
8957. Reel for Water Tubes, H. W. Handcock and A. H. Dykes, London.
8958. Turning Over Leaves of Music, W. J. Pitt, London.
8959. Preparing Sheet Iron and Steel, J. D. Grey, London.
8960. Smoke-consuming Devices, H. H. Lake.—(*P. Sertschansky, France.*)
8961. Wrench for Turning Pipes, M. D. Martindale, London.
8962. Musical Instruments, O. Imray.—(*N. Merrill and A. W. Jones, United States.*)
8963. Musical Instruments, O. Imray.—(*N. Merrill and A. W. Jones, United States.*)
8964. Electrical Furnaces, O. Imray.—(*D. Graham, Canada.*)
8965. Drilling Holes in Brush Bodies, C. E. Flemming, London.
8966. Boot Tree or Boot Stretcher, M. Renault, London.
8967. Recovery of Precious Metals, S. Vivian, London.
8968. Cork-cutting Machines, J. A. Lafrance, London.
8969. Unfastening Doors, E. Edwards.—(*H. Hufschmidt, Germany.*)
8970. Braces, T. Parkin, London.
8971. Defensive Works for Laagers, P. B. Tod, London.
8972. Gear Chains for Bicycles, C. A. McCombie, London.
8973. Organs, R. P. Strand, D. B. Carritte, and C. A. Stockton, London.
8974. Fire Extinguishers, C. R. Arents and W. R. Johnston, London.
8975. Bottles, R. S. Dickerson, London.
8976. Sewing Machines, J. W. Mackenzie.—(*W. H. Boyer and The American Special Machinery Company, Limited, United States.*)
8977. Sanitary Paper for Toilet Purposes, A. Pitt and D. Stuart, London.
8978. Coal Crushers, S. Evans and F. J. Morgan, London.
8979. Typewriting Machines, A. M. Clark.—(*The Wagner Typewriter Company, United States.*)
8980. Motors, &c., A. J. Boult.—(*K. Henschel, Germany.*)
8981. Substitute for White Lead, &c., S. Ganelin, London.
8982. Artificial Hair Constructions, G. and H. Lichtenfeld, London.
8983. Stoppering Bottles, J. Prince and S. Higton, London.
8984. Machines for Opening Meat Tins, &c., G. Steer, London.
8985. Covers for Tobacco Pipes, T. Hooper, S. G. Moore, and F. R. Baker, London.
8986. Handle-bars of Bicycles, W. E. Webb, London.
8987. Water Gauges, J. Hopkinson and J. Lowis, London.
8988. Arc Lamps, W. P. Thompson.—(*M. Wholess, United States.*)
8989. Bicycles, W. P. Thompson.—(*H. N. Timms, United States.*)
8990. Grinding Flats in Carding Engines, W. P. Thompson.—(*J. C. Potter, United States.*)
8991. Field Glasses, W. P. Thompson.—(*E. Toussaint, Germany.*)
8992. Turbines, G. Kürtösi, London.
8993. Weighing Appliances, J. Trantom, Liverpool.
8994. Hook for Curtain Draperies, G. H. Hill, Birmingham.
8995. Incandescent Gas Lamps, J. Bartels, Liverpool.

29th April, 1896.

8996. Cycles, F. H. Keene, Ireland.
8997. Lamp Stoves, G. Salter and C. J. Holdship, Birmingham.
8998. Separating Solutions from Materials, C. J. Ellis, Glasgow.
8999. Multiplex Telephony, A. M. Rosebrugh, Canada.
9000. Wheels, W. Ives, Halifax.
9001. Increasing the Buoyancy of Ships, R. Baird, Glasgow.
9002. Regulators for Steam Engines, R. Gee, Huddersfield.
9003. Treatment of Alimentary Substances, J. Hogarth, Glasgow.
9004. Valves, C. H. Holgate, Leeds.
9005. Pneumatic Tires, J. Birtwistle, Manchester.
9006. Boat Disconnecting Gear, &c., F. S. Pett, Dover.
9007. A Non-fillable Bottle, T. Dawson, Birkdale.
9008. Attaching Flexible Coil Tires, C. Challiner, Manchester.
9009. Introduction of Different Colours, H. Fothergill, Leeds.
9010. Means for Carrying Coal, G. Simpson, London.
9011. Appliances for Carrying Bags, E. J. Pinder, Sheffield.
9012. Cycle Tires, R. H. Edmundson, Manchester.
9013. Bells, C. B. Wright and F. L. Sanders, Nottingham.
9014. Electric Temperature Alarms, G. J. Baird, Glasgow.
9015. Raising Vessels, J. B. Murray and J. P. Turnbull, Glasgow.
9016. Motor-driven Velocipedes, J. J. H. Sturmey, Coventry.
9017. Adjustable Lock Jaw Spanner, J. Reid, Millom.
9018. Machine Tool or Cutter Holders, S. Griffin, Bath.
9019. Signals for Railways, W. H. Hallsworth, Ashton-under-Lyne.
9020. Fastener for Wearing Apparel, M. Bach, Manchester.
9021. Bar to Prevent Entanglement of Cotton, L. Martindale, London.
9022. Head-lights for Railway Cars, F. E. Huntress, London.
9023. Clips, F. S. Rippingille, London.
9024. Stoves, F. S. Rippingille, London.
9025. Self-acting Tip Box, &c., J. H. Simpson, London.
9026. Apparatus for Holding Plates, W. O. Bailey, London.
9027. Pneumatic Tires, J. Pearson, J. B. Price, and E. T. Whitelow, Manchester.
9028. Holding Bobbins, J. H. Smith, O. H. Hartley, and R. N. Wailes, London.
9029. Bicycle Apparatus, F. E. Macmahon and A. J. Postans, London.
9030. Automatic Electrical Cut-out, W. W. Channon, London.
9031. Manufacture of Hats, T. Lees, T. H. Lees, and W. Morgan, London.
9032. Voxometer, A. A. North, P. Nind-Ward, and E. W. Pidgeon, London.
9033. Wire-drawn Benches, C. Bremicker, Germany.
9034. Hydrostatic Engines, C. Stimpson, London.
9035. Coin-freed Apparatus, G. Haydon and Haydon and Urry, Limited, London.
9036. Rocking and Folding Chair, C. Vogel, jun., London.
9037. Conveying Coke from Gas Retorts, J. Browne and J. Rice, London.
9038. Ploughs, J. Hornsby, J. Money, and W. Grice, London.
9039. Pear-shaped Steel Spring Truss, J. Robinson, Bucks.
9040. Pedals for Bicycles, J. Monteith, London.
9041. Treatment of Tin Ore, S. O. Cowper-Coles, London.
9042. Feed-water Heaters, W. P. Thompson.—(*J. F. Hauser, Germany.*)
9043. Electric Transmitting Apparatus, T. S. Baltazzi, Liverpool.
9044. Rotary Flat Sieves, J. Higginbottom, Liverpool.
9045. Brakes for Bicycles, G. Bradley and J. Moorhouse, Manchester.
9046. Pneumatic Tires, G. Williams, jun., Liverpool.
9047. Heating by Electricity, T. D. Farrall, London.
9048. Electric Fog Signalling Apparatus, H. Tomlins and C. R. Gurr, London.
9049. Pile-fabric Cutting Frames, J. Welsby and J. Whittaker, Liverpool.
9050. Holding or Supporting Fabrics, W. B. Mulligan, London.
9051. Cycle Saddles, T. Middlemore and T. Evans, London.
9052. Motors, A. A. Loyal, London.
9053. Tennis Rackets, E. R. Butler, London.
9054. Presser Clamp, Hope-street Factory, Ld., and J. Laird, London.
9055. Fireproof Cements and Varnishes, I. A. Timmis, London.
9056. Automatic Gas Lighting Devices. G. Loewenberg, London.
9057. Attachment for Beer Engines, W. Granville, London.
9058. Race Courses or Race Tracks, S. E. Moss, London.
9059. Bicycle Supports, J. J. McKanna and C. Lindstrom, London.
9060. Telephones, G. L. Anders and J. E. Wedekind, London.
9061. Giving Sound and Light as Alarums, M. Wilson, London.

30th April, 1896.

9062. Vertical and other Steam Boilers, J. R. Robson, Leeds.
9063. Door Latch, D. Smith, Blackburn.
9064. Lubricating Bearings, G. Kyte and Co., Cardiff.
9065. Fire-lighter, T. S. Blakeway, Manchester.
9066. Knitting Material Holders, W. J. Simmons, Bristol.
9067. Pneumatic Tires, V. Brown and R. J. Royle, Lancashire.
9068. Wick for Burners, &c., H. W. Scothon, Nottingham.
9069. Consuming Furnace Smoke, Starkey Bros., Ld., and F. Hinchliffe, Huddersfield.
9070. Cutting Gelatinous Substances, J. W. Atkinson, G. Bramley, and J. Todd, Bradford.
9071. Improved Motor, C. E. Agar and H. Ainsworth, Manchester.
9072. Needle Threaders, J. Darling and T. Clarke, Glasgow.
9073. Railway Carriage Windows, H. Macaulay, Glasgow.
9074. Sunshades, &c., for Bicycles, J. J. Wagstaff, Newport, Pagnell.
9075. Coating Pills, R. Gibbins, Derby.
9076. Making White Arsenic, T. P. Sims and W. Terrill, Swansea.
9077. Uncoupling Cattle, W. Straube and The Actiengesellschaft Maschinenfabrik Landsberg-on-the-Lech, London.
9078. Glass Wares, W. Straube and The Actiengesellschaft Maschinenfabrik Landsberg-on-the-Lech, London.
9079. Incandescent Lamps, W. R. Lane and Winfields, Ld., London.
9080. Taking Pills from Vials, C. Toft, Staffordshire.
9081. Tires for Vehicles, C. E. Harrison, Birmingham.
9082. Machine for Perforating Cheques, S. Draper, London.
9083. Propelling Cycles, F. O. Ferguson, Ilfracombe.
9084. Apparatus for Distilling, J. Longshaw, Manchester.
9085. Preparing Fluid Extracts, J. Longshaw, Manchester.
9086. Staple to Fasten to Deeds, J. L. Phillips, Llanelly.
9087. Tag for Fixing Plants to Walls, J. H. Gibson, Southport.
9088. Sheep Trucks, J. J. McMurdo and G. Symington Glasgow.
9089. Mechanically Unloading Lorries, C. Flower, Glasgow.
9090. Taps for Hot and Cold Water, A. Clifford, Kent.
9091. Key-ring Appliances G. H. Laxton, London.
9092. Oil and Gas Engines, H. Tubb and A. E. Mondey, Southampton.
9093. Cycles, J. Corp, London.
9094. Constructing Bicycle Tires, J. C. Cole, London.
9095. Washing Machines, W. Smith, D. Marks, and R. Watson, Keighley.
9096. Propelling Apparatus for Ships, G. D. Macdougald, Dundee.
9097. Tires for Cycle Wheels, S. B. Wilkins, Edinburgh.

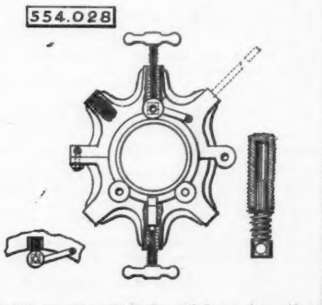
SELECTED AMERICAN PATENTS.

From the United States Patent Office Official Gazette.

554,028. Pipe-cutter, *J. N. Marso, Joliet, Ill.—Filed November 29th*, 1895.

Claim.—(1) In a pipe-cutter, the combination of the frame A formed in two parts and hinged together and having the nut and bolt G for locking the two parts of said frame together on the pipe to be cut, and having the bar-holes F, the bit H, screw I attached to said bit, the screw E having a hollow inner end, the rod K having its inner end arranged in the chamber of screw E, coil spring J sleeved on said rod between its head and screw E, friction wheels B' and their axle attached to rod K, links C for pivotally connecting said wheels with frame A, and the friction wheels B and their axles all arranged to operate substantially as and for the purpose set forth. (2) In a pipe-cutter, the combination of the jointed frame A, and the means for clamping it on a pipe to be cut, the adjustable bit H, the friction wheels B, the hollow screw E, rod K fitting the hollow of said screw and having an axle attached to its outer end, the friction wheels B′ on said axle, the links for pivotally connecting said wheels and their axle with the frame A, and the coil spring sleeved on said rod between its head and screw E, all arranged to operate substantially as and for the purpose set forth.

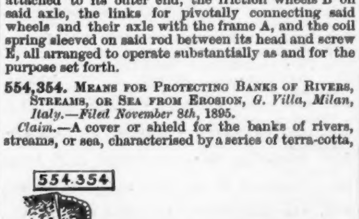
554.028



554,354. Means for Protecting Banks of Rivers, Streams, or Sea from Erosion, *G. Villa, Milan, Italy.—Filed November 8th*, 1895.

Claim.—A cover or shield for the banks of rivers, streams, or sea, characterised by a series of terra-cotta, or cement—or other suitable material—plates *a*, connected with each other by means of wires *b*, the longitudinal layers of which are held together at the bottom of the river by a wooden—or like—bar *c*, while they are fixed at the top of the bank by wires fastened to trees, piles, or the like, driven into the bank.

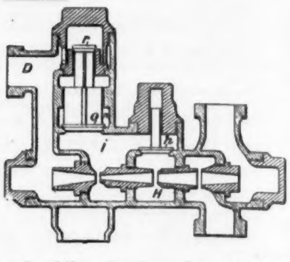
554.354



554,415. Injector, *J. Desmond, Detroit, Mich.—Filed November 11th*, 1893.

Claim.—(1) In an injector, the combination of the casing, partitions therein to form the communicating chambers H I, having an overflow common to both, the combining and delivery tubes having a spill-opening into the chamber I, the valve *h* in the passage between the chambers and the valve *o* for the overflow located between the chamber I and the overflow passage, substantially as described. (2) In an injector, the combination of the casing, partitions therein to form the chambers H I, the overflow passage *n*, discharge D, of the valves *h o* and *r*, substantially as described. (3) The combination of the combining and delivery chambers having a spill-passage therefrom, communicating with the chamber I, the valve *o* being constructed to permit fluid above the same to enter the chamber I and the valve *r* subject to pressure from the delivery and adapted to close the valve *o*, substantially as described.

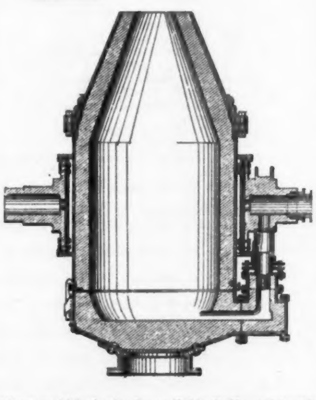
554.415



554,457. Pneumatic Converter, *C. S. Price, Westmont, Pa.—Filed April 10th*, 1895.

Claim.—(1) In a pneumatic converter, a bottom section lined solidly in its lower portion with refractory material, provided with a side blast inlet at or near the upper surface of said bottom lining, and a removable elbow lined with refractory material in which is formed part of the blast inlet, said latter portion of the blast inlet being connected at one end to a suitable blast pipe and at the other to the main body of the bottom, said elbow being removably secured to said bottom and blast pipe by suitable bolts, substantially as described. (2) In a pneumatic converter, a bottom section lined with refractory material, and a side blast inlet formed in the side lining of said bottom and connected to a suitable source of air supply, by means of an elbow lined with refractory material and provided at or near its upper end with a perforated tuyere block, said tuyere being so arranged as to be readily removed and replaced, substantially as set forth.

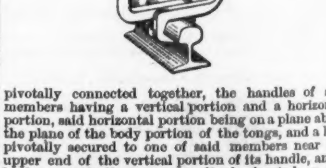
554.457



554,461. Rail Tongs, *E. Schrantz, Warrington, Mo.—Filed November 6th*, 1895.

Claim.—(1) A rail tongs, comprising two members, one of said members carrying the pivot pin and the other of said members being formed with a slot to receive said pin, said slot being somewhat enlarged at one end, substantially as described. (2) A rail tongs, comprising two members which are slidingly and pivotally connected together, the handles of said members having a vertical portion and a horizontal portion, said horizontal portion being on a plane above the plane of the body portion of the tongs, and a link pivotally secured to one of said members near the upper end of the vertical portion of its handle, and a hook or projection correspondingly located on the other member, and with which said link is adapted to engage, substantially as described.

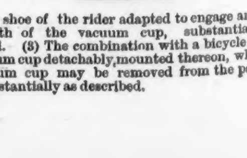
554.461



554,686. Vacuum Cup Bicycle Pedal, *E. T. Harris and A. S. Reed, Chicago, Ill.—Filed July 24th*, 1895.

Claim.—(1) The combination with a bicycle pedal, of a vacuum cup provided thereon, adapted to be engaged by the foot of the rider, substantially as described. (2) The combination with a bicycle pedal, of a vacuum cup provided thereon and a plate provided upon the shoe of the rider adapted to engage and seal the mouth of the vacuum cup, substantially as described. (3) The combination with a bicycle pedal, of a vacuum cup detachably mounted thereon, whereby the vacuum cup may be removed from the pedal at will, substantially as described.

554.686



AUXILIARY ENGINES IN SCREW STEAMERS.

IN a series of articles which we published last year—see vol. lxxx., pages 228, 299, 379, 448, 522, 543—most of the details connected with the fitting of the main engines and boilers on board a screw steamer were explained. In this article we intend to draw attention to some of the more important engine-room accessories.

In the early days of high-pressure steam, it was thought desirable to use sea-water in the boilers, in order that the heating surfaces might become covered with scale, which was thought to prevent, or at least minimise, corrosion; and as long as such views prevailed, the idea of fitting distilling appliances, or evaporators as they are more commonly called on board, was scouted as being ridiculous. It was the inventors of water-tube boilers who discovered to their cost that sea water was fatal to their creations. Fresh-water tanks had therefore to be fitted in such steamers, but as the loss of water from a marine engine and boiler may amount to one ton a day per 100 indicated horse-power, it was soon found that such tanks would have to be of enormous dimensions if used on long voyages, and it proved to be more convenient and also more profitable to fit evaporators. Originally these were small boilers heated by fires and exhausting either into one of the receivers or into the condenser, but this arrangement was a troublesome one, and soon gave way to an apparatus in which the evaporation is effected by steam which passes through coils submerged in salt water. As soon as this water begins to boil, the steam thus generated passes either into one of the receivers or into the condenser. Many alternative arrangements may be, and are being, worked. Thus some evaporators receive their steam from No. 1 receiver, and the generated steam is delivered into No. 2 receiver, while the condensed steam is drained into the hot well; the three quantities being equal, there is a loss of about 2 per cent. of power, because of the reduced quantity of steam in the intermediate cylinder, but there is a gain of about 1½ per cent. of heat in the feed. On account of the comparatively small difference of temperature between the two receivers, which is still further reduced in the evaporator, its heating surface will only evaporate about 20 lb. of water per sq. ft. per hour, or approximately one quarter ton per day. By connecting the steam coils to the main boiler, and the exhaust pipe to the condenser, the performance of such an evaporator could be increased fourfold, or for the same sized engine its heating surface could be diminished to one-fourth, because each square foot would now evaporate about one ton per day, but the external size of the evaporator could not be reduced; in fact, it would doubtless have to be increased, for, on account of the low pressure in the condenser, the volume of the generated steam would be enormous, and with a low crown to the evaporator, priming would be sure to take place; as the water in the evaporator ultimately contains much salt, it might happen that the newly formed steam would prime over as much salt, or sometimes more, than is contained in the sea. This arrangement must also be considered an uneconomical one, for the steam which is condensed in the evaporator does no work, and as its final temperature is only slightly higher than that of the condenser, no benefit is derived by leading it into the feed. The total loss of steam amounts to about 7 per cent., which is a heavy price to pay for distilling 7 per cent. of sea water.

Much uncertainty prevails as to how to determine the quantity of water produced in an evaporator, but it is really a very simple matter. First of all, the evaporator is filled with water to the usual working level in the gauge glass; this water is then run out into gallon measures, and the internal capacity up to any given mark is thus found. The evaporator is then refilled and set to work. Every time before blowing it out a sample is drawn off, and its density measured. Should this be found to contain, say, 25 oz. of salt to the gallon, whereas sea water only contains 5 oz., then evidently four times as much water as is still contained in the evaporator has been distilled. Another plan is to shut off the supply and to note the speed with which the water level in the evaporator is reduced, but this must necessarily be a short and unsatisfactory experiment. The usual method of working an evaporator is to fill it with sea water up to a certain height, which can be seen on the gauge glass; then the exhaust pipe is opened, then the drain to the hot-well, and then the steam stop valve is opened. The amount of steam condensed depends not only on the available differences of pressure or temperature, but also on the openings of the various valves, &c. The maximum quantity is of course produced if the stop valve and drain cock are full open, but the sea water would soon dry up, and has to be added to by a small separate feed pump whose suction valve can be regulated so that just sufficient more water is admitted. If less water has to be evaporated, this suction valve and also the steam stop valve or the drain cock are partially closed. If the exhaust pipe is a small one, particularly when connected to the condenser, the evaporation will be somewhat reduced. After a few hours' working, and when the saltness of the water has increased considerably, the feed is stopped and the blow-off cock opened. The pressure in the evaporator will, of course, drive out the concentrated brine. If, however, the exhaust pipe is connected to the condenser, then this pipe must first be closed, and a little time will elapse before the pressure has risen sufficiently to overcome the external head of sea water. When this point has been reached the blow-off cock is opened and the brine ejected. The evaporator is then refilled and the process repeated about once every watch. After working like this for a few days, the proceeding is altered a little. The concentrated brine is blown out, the blow-off closed until the pressure and temperature in the evaporator has risen as high as circumstances will allow. The steam is then shut off and the blow-off cock opened, and after a very short period the sea will be drawn in, and coming into contact with the hot steam coils and the scale which adheres to them, will cause the latter to crack off and fall to the bottom. Contrary to expectations, no injury seems to accrue to the evaporator by this proceeding, and it is therefore better to clean it in this manner than to nurse it carefully and ultimately to chip the scale off in port, whereby the tubes are soon worn through.

In addition to an evaporator, passenger ships carry a distilling apparatus, or small independent condenser. The necessary steam is supplied by the evaporator, and the condensed water has therefore no oily taste. The cooling water is taken from the circulating pump of the main engine. Of course the evaporator may not in this case be connected to the main condenser, otherwise there will be no tendency for the condensed water to flow out of the still.

Another very necessary engine-room fitting is the oil filter; its object is to free the feed of all oil before it enters the boilers, whereby the heating surfaces are kept clean, their heat-transmitting power maintained, and all danger of overheating reduced to a minimum. Oft repeated experiments have proved that even very thin films of oil, with which a heating surface may have become coated, add enormously to the heat-resisting power of the plates. Whether this is due to the very low thermal conductivity of oils, or whether it is due to the artificial smoothness or greasiness of the surface, whereby the formation of bubbles is discouraged, has not been decided, but there can be no doubt that a far greater amount of oil may be tolerated in a boiler whose heating surface is well covered with scale, than in one where no scale has been allowed to form, this may perhaps account for the fact that collapses of furnaces due to oil are relatively more frequent in new boilers than in old ones. That a very slight amount of oil will seriously interfere with the evaporation can easily be demonstrated by pouring samples of fresh water and milky feed-water from a marine engine into two new saucepans and boiling them. The fresh water will boil quite steadily, while the oily feed-water will boil spasmodically. If after a short time the feed-water is poured away and fresh water placed in its saucepan, the boiling will still be irregular, showing that this is due to an oily deposit, which, although it is invisible, can be shown to exist by rubbing the inside of the pan with a white rag.

The general principle of an oil filter is that the feed is made to pass through several thicknesses of some woven material, to which the oil is supposed to adhere. It is needless to say that as soon as the advantages of oil filters had been demonstrated, numerous designs were at once got out. At first all other considerations were sacrificed to the one of efficiently removing all the grease out of the water, which was, therefore, made to pass through many membranes, but it has been found that all the grease does not get removed, and that the best filtering medium is the grease itself, which collects on the membranes—or, in other words, the dirtier a filter is, the better it acts. But this is only true so long as the pressure which is required to force the feed through the filter is not excessive. Should it rise too high, the accumulated grease is forced through the membrane, or the latter bursts. This is, perhaps, one of the reasons why most filters are fitted with safety valves, which are set to a pressure of about 30 lb. in excess of the boiler pressure. By-pass valves, set to about 30 lb. per square inch, have been tried, and certainly do not waste any water when the maximum pressure has been reached, because it then goes straight into the boiler; but they have to be fitted with signalling appliances, which inform the engineer when the filter requires cleaning, and these appliances either get out of order or are disconnected, and the filter is not attended to as thoroughly as it should be. If an escape valve is fitted, the overflowing water compels attention.

In the early filters the cleaning of the membranes was a very troublesome and dirty job, each one having to be removed, scraped, and replaced. For convenience they were fitted with flat frames, and consequently took up much room. The more modern practice is to clean the filter by passing a reverse current, either of steam or water, through the filter and blowing the mud overboard. Under such conditions the flat membranes need not of course be adhered to, and the aim with all modern filters seems to be to make their bulk as small as possible, with the largest possible surface. Lenticular, cylindrical, and star-shaped frames, on which the membranes are stretched, have since then become quite common. On the other hand, as these filters are subjected to great heat, flannel, which is certainly a very good filtering material, has had to be replaced by linen, cotton, and cocoa-nut fabrics; the latter, in particular, seems to be a great favourite.

When the boilers are fed direct by the main engine pumps, the filter is invariably fitted between the two, although of course pipes could be led from the hot-well to the filter, and thence to the pumps, but in this case the available head of pressure would not be great, and the filter would have to be cleaned very often, or its area would have to be a very large one. If independent slow-working feed pumps are used, together with an overhead tank, the filter is frequently connected either to the pipes leading to this tank, or to those coming from the tank, so that the water is as pure as it can be made before it reaches the pumps. In neither case is a safety valve necessary, except as a safeguard for the filtering material, as it might tear if too great a thickness of grease were allowed to accumulate. Its amount will, of course, depend on the quantity of oil injected into the cylinders, which in modern engine-room practice has been reduced to a minimum, absolutely no oil being injected; in fact, the only points where the steam now comes in contact with the grease is at the piston-rods. At first sight it would appear that this quantity is too small to be worth troubling about, but it is a fact that even under these circumstances considerable deposits of grease collect in the filters, and the feed-water, even after being thus cleared, has a slightly milky appearance and an oily taste. By some it is believed that the coarse grease, which is easily separated from the water by the filter, is not dangerous to the boiler, as it is this portion which at once rises to the water level and adheres to the shell plates and steam stays, whereas the greasy coating on the heating surfaces, and particularly on the furnace tops, is believed to be due to the finely divided or dissolved oil in the water, which seems to pass through all filtering materials that have yet been tried. However, as no case of collapsed furnaces has occurred in vessels fitted with oil filters, and their number is daily increasing, it is but reasonable to suppose that this invention is a real safeguard.

Mention has already been made of automatic feed pumps. They owe their introduction to a well-grounded belief that the internal corrosion of marine boilers is mainly due to the air which is forced into them by the feed pumps. These, as is well known, are made twice as large as need be, even when the engine is working full power, and under ordinary conditions they deliver quite twice as large a volume of air as of water, or about ¼ per cent. of its weight. One way of keeping this air out of the pumps would be to partially close their suctions, but the inconveniences attending this method are so many and so self-evident that it has probably never been tried. However, the principle has survived, and has been adopted in automatic feed-pumping arrangements. The water, after it leaves the hot-well is forced up into a tank placed near the skylights, where it parts with its air. This tank contains a powerful float, which actuates the stop valve of the automatic feed pumps and causes them to stop if the water level sinks, whereas, if suddenly a large volume of feed-water enters the tank, the float rises, opens the stop valve, and sets the pumps working full speed. These pumps are, of course, direct-acting. It will thus be seen that on account of the great height of the tank above the pumps, these are always full of water, and as they are of the slow working type, and are not fitted with snifting valves, every possibility of introducing air into the boiler has been removed, and, as far as can be judged, with beneficial results.

Automatic pumps are generally fitted with counters, which record the number of strokes and enable one to estimate the volume of feed, but only approximately, for the leakages are considerable, they increase with age, and are affected by the speed at which the pumps are worked; the stroke also varies considerably in the same pump. From an economical point of view, particularly as a check on the coal consumption, a knowledge of the feed supplied is valuable, and some modern ships are fitted with feed meters, but they can only be used together with automatic pumps, for the air which is delivered by the main feed pumps would in passing through the meter also be measured and recorded.

The overhead tank is frequently so arranged that it receives steam from one of the intermediate receivers, whereby the temperature of the feed-water passing through it is raised, but if we are not mistaken, this causes fluctuations, not only in the water level but also to a slight extent in the power developed by the engine, as will be seen if one supposes that through some external but temporary cause an excess of steam passes through the engine, it will, after being condensed, reach the tank and feed-heater just when the main engines are slowing down again, but the larger volume of water which just then passes through the feed-heater causes a larger volume of steam to be condensed, and as this is drawn out of one of the receivers the engine will be slowed down still more. Withdrawing the steam for a feed-heater from the main engine has, therefore, the contrary effect of a governor. Independent feed-heaters are sometimes fitted. Of course it is well known that the drains from the jackets add heat to the feed, and also that it is advantageous to draw off the water which accumulates in the various receivers, but this can easily be done by leading the pipes into the hot-well.

Neither the evaporator nor the oil filters, nor the automatic feed pump, are absolutely necessary in an engine-room, but as they add to the life and to the security of the boilers, most large steamers are now fitted with them. There are, however, other auxiliary engines which may not be omitted; these are the ballast pump in tank vessels, which has, of course, to be used chiefly in port, a separate donkey pump which has to be relied upon for clearing the bilges of water when the main engine is stopped, or its pumps out of order. It is also used for filling the boilers in port, and its suctions are arranged so that water can be drawn both from the bilges, the sea, hot well, tanks, and the boiler; and the deliveries are overboard, on deck, into the boiler, and into the condenser. In small steamers the ballast and donkey pump are sometimes, but not frequently, fused into one. Passenger ships are also supplied with a sanitary pump, which ought, of course, to be kept perfectly distinct from the bilge pipes, yet, strange to say, the fatal connection is very frequently insisted upon by the owners' representative, with the disastrous result that the baths are accidentally supplied with greasy bilge water. Even the bare idea that sanitary water is made to pass through the same pipes which occasionally draw filthy water ought to lead to an entire separation of the two.

Some small steamers, particularly those engaged in the fishing trade, have powerful ejectors, which, if they are not very economical, are certainly very effective in clearing the bilges, not only of water, but also of fish refuse and other substances that find their way there, which could not be done by pumps, on account of the restricted areas at the valves. Ash ejectors are worked on the same principle, but are little used because of the rapidity with which their ducts are said to corrode. Steam ash hoists have, of course, to be fitted to all large steamers, and seem to work very satisfactorily.
